He returned to Rome in 77 B.C., and appears to have married at this time Terentia, a rich woman with a domineering temper, to whom many of his subsequent embarrassments were due.¹ He engaged at once in forensic and political life. He was quaestor in 75, and was sent to Lilybaeum to supervise the corn supply. His connection with Sicily let him to come forward in 70 B.C., when curule-aedile elect, to prosecute Gaius Verres, who had oppressed the island for three years. Cicero seldom prosecuted, but it was the custom at Rome for a rising politician to win his spurs by attacking a notable offender (*pro Caelio*, 73). In the following year he defended Marcus Fonteius on a charge of extortion in Gaul, using various arguments which might equally well have been advanced on behalf of Verres himself.

In 68 B.C. his letters begin, from which (and especially those to T. Pomponius Atticus, his "second self") we obtain wholly unique knowledge of Roman life and history. In 66 B.C. he was praetor, and was called upon to hear cases of extortion. In the same year he spoke on behalf of the proposal of Gaius Manilius to transfer the command against Mithridates from Lucullus to Pompey (*de Lege Manilia*), and delivered his clever but disingenuous defence of Aulus Cluentius (*pro Cluentio*). At this time he was a prospective candidate for the consulship, and was obliged by the hostility of the nobles towards "new men" to look for help wherever it was to be found. In 65 B.C. he even thought of defending Catiline on a charge of extortion, and delivered two speeches on behalf of Gaius Cornelius, tribune in 67 B.C., a leader of the democratic party. In 64 B.C. he lost his father and his son Marcus was born. The optimates finally decided to support him for the consulship in order to keep out

Catiline, and he eagerly embraced the "good cause," his affection for which from this time onward never varied, though his actions were not always consistent.

The public career of Cicero henceforth is largely covered by the general article on ROME: *History*. The year of his consulship (63) was one of amazing activity, both administrative and oratorical. Besides the three speeches against Publius Rullus and the four against Catiline, he delivered a number of others, among which that on behalf of Gaius Rabirius is especially notable. The charge was that Rabirius (*q.v.*) had killed Saturninus in 100 B.C., and by bringing it the democrats challenged the right of the senate to declare a man a public enemy. Cicero, therefore, was fully aware of the danger which would threaten himself from his execution of the Catilinarian conspirators. He trusted, however, to receive the support of the nobles. In this he was disappointed. They never forgot that he was a "new man," and were jealous of the great house upon the Palatine which he acquired at this time. Caesar had made every possible effort to conciliate Cicero,¹ but, when all overtures failed, allowed Publius Clodius to attack him. Cicero found himself deserted, and on the advice of Cato went into exile to avoid bloodshed. He left Rome at the end of March 58, and arrived on May 23 at Thessalonica where he remained in the deepest dejection until the end of November, when he went to Dyrrhachium (Durazzo) awaiting his recall. He left for Italy on Aug. 4, 57, and on arriving at Brundisium (Brindisi) found that he had been recalled by a law passed by the *comitia* on the very day of his departure. On his arrival at Rome he was received with enthusiasm by all classes, but did not find the nobles at all eager to give him compensation for the loss of his house and villas, which had been destroyed by Clodius. He was soon encouraged by the growing coolness between Pompey and Caesar to attack the acts of Caesar during his consulship, and after his successful defence of Publius Sestius on March 10 he proposed on April 5 that the senate should on May 15 discuss Caesar's distribution of the Campanian land. This brought about the conference of Luca (Lucca). Cicero was again deserted by his supporters and threatened with fresh exile. He was forced to publish a "recantation," probably the speech *de Provinciis Consularibus*, and in a private letter says frankly, "I know that I have been a regular ass." His conduct for the next three years teems with inconsistencies which we may deplore but cannot pass over. He was obliged to defend in 54 Publius Vatinius whom he had fiercely attacked during the trial of Sestius; also Aulus Gabinius, one of the consuls to whom his exile was due; and Rabirius Postumus, an agent of Gabinius. On the other hand, he made a violent speech in the senate in 55 against Lucius Piso, the colleague of Gabinius in 58. We know from his letters that he accepted financial aid from Caesar, but that he repaid the loan before the outbreak of the civil war. There is no doubt that he was easily deceived. He was always an optimist, and thought that he was bringing good influence to bear upon Caesar as afterwards upon Octavian. His actions, however, when Caesar's projects became manifest, sufficiently vindicated his honesty. During these unhappy years he took refuge in literature. The *de Oratore* was written in 55 B.C., the *de Republica* in 54, and the *de Legibus* at any rate begun in 52. The latter year is famous for the murder of Clodius by T. Annius Milo on the Appian Way (on Jan. 18), which brought about the appointment of Pompey as sole consul and the passing of special laws dealing with rioting and bribery. Cicero took an active part in the trials which followed both as a defender of Milo and his adherents and as a prosecutor of the opposite faction. At the close of the year, greatly to his annoyance, he was sent to govern Cilicia under the provisions of Pompey's law (*see POMPEY and ROME: History*). His reluctance to leave Rome, already shown by his refusal to take a province, after his praetorship and consulship, was increased by the inclination of his daughter Tullia, then a widow, to marry again.

¹According to Plutarch she urged her husband to take vigorous action against Catiline, who had compromised her half-sister Fabia, a vestal virgin; also to give evidence against Clodius, being jealous of his sister Clodia.

¹Caesar, at one time, offered him a place on the coalition, which on his refusal became a triumvirate (*Att.* ii. 3. 3; *Prov. Cons.* 41), and afterwards a post on his commission for the division of the Campanian land, or a *legatio libera*.

During his absence she married the profligate spendthrift, P. Cornelius Dolabella.

The province of Cilicia was a large one. It included, in addition to Cilicia proper, Isauria, Lycaonia, Pisidia, Pamphylia and Cyprus, as well as a protectorate over the client kingdoms of Cappadocia and Galatia. There was also danger of a Parthian inroad. Cicero's legate was his brother Quintus Cicero (below), an experienced soldier who had gained great distinction under Caesar in Gaul. The fears of Parthian invasion were not realized, but Cicero, after suppressing a revolt in Cappadocia, undertook military operations against the hill-tribes of the Amanus and captured the town of Pindenissus after a siege of 46 days. A *supplicatio* in his honour was voted by the senate. The early months of 50 were occupied by the administration of justice, chiefly at Laodicea, and by various attempts to alleviate the distress in the province caused by the exactions of his predecessor, Appius Claudius. He had to withstand pressure from influential persons (e.g., M. Brutus, who had business interests in his province), and refused to provide his friends with wild beasts for their games in Rome. Leaving his province on the earliest opportunity, he reached Brundisium on Nov. 24, and found civil war inevitable. He went to Rome on Jan. 4, but did not enter the city, since he aspired to a triumph for his successes. After the outbreak of war he was placed by Pompey in charge of the Campanian coast. After much irresolution he refused Caesar's invitations and resolved to join Pompey's forces in Greece. He was shocked by the ferocious language of his party, and himself gave offence by his bitter jests (Plut. *Cic.* 38). Through illness he was not present at the battle of Pharsalus, but afterwards was offered the command by Cato the Younger at Corcyra, and was threatened with death by the young Cn. Pompeius when he refused to accept it. Thinking it useless to continue the struggle, he sailed to Brundisium, where he remained until Aug. 12, 47, when, after receiving a kind letter from Caesar, he went to Rome. Under Caesar's dictatorship Cicero abstained from politics. His voice was raised on three occasions only: once in the senate in 46 to praise Caesar's clemency to M. Claudius Marcellus (*pro Marcello*), to plead in the same year before Caesar for Quintus Ligarius, and in 45 on behalf of Deiotarus, tetrarch of Galatia, also before Caesar. He suffered greatly from family troubles at this period. In 46, he divorced Terentia, and married his young and wealthy ward, Publilia. Then came the greatest grief of his life, the death of Tullia, his beloved daughter. He shortly afterwards divorced Publilia, who had been jealous of Tullia's influence and proved unsympathetic. To solace his troubles he devoted himself wholly to literature. To this period belong several famous rhetorical and philosophical works, the *Brutus*, *Orator*, *Partitiones Oratoriae*, *Paradoxa*, *Academica*, *de Finibus*, *Tusculan Disputations*, together with other works now lost, such as his *Laus Catonis*, *Consolatio* and *Hortensius*.

His repose was broken by Caesar's murder on March 15, 44, to which he was not a party. On March 17 he delivered a speech in the senate urging a general amnesty like that declared in Athens after the expulsion of the Thirty Tyrants. When it became apparent that the conspirators had removed only the despot and left the despotism, he again devoted himself to philosophy, and in an incredibly short space of time produced the *de Natura Deorum*, *de Divinatione*, *de Fato*, *Cato maior* (or *de Senectute*), *Laelius* (or *de Amicitia*), and began his treatise *de Officiis*. To this period also belongs his lost work *de Gloria*. He then projected a journey to Greece in order to see his son Marcus, then studying at Athens, of whose behaviour he had heard unfavourable reports. He reached Syracuse on Aug. 1, having during the voyage written from memory a translation of Aristotle's *Topica*. He was driven back by unfavourable winds to Leucopetra, and then, hearing better news, returned to Rome on Aug. 21. He was bitterly attacked by Marcus Antonius (Mark Antony) in the senate on Sept. 1 for not being present there, and on the next day replied in his First *Philippic*. He then left Rome and devoted himself to the completion of the *de Officiis*, and to the composition of his famous Second *Philippic*, which was never

delivered, but was circulated, at first privately, after Antony had made his departure from Rome on the way to Cisalpine Gaul on Nov. 28.

Cicero returned to Rome on Dec. 9, and from that time forward led the republican party in the senate. His policy, stated briefly, was to make use of Octavian, whose name was all-powerful with the veterans, until new legions had been raised which would follow the republican commanders. Cicero pledged his credit for the loyalty of Octavian, who styled him "father" and affected to take his advice on all occasions. Cicero, an incurable optimist in politics, may have convinced himself of Octavian's sincerity. The breach, however, was bound to come, and the saying, maliciously attributed to Cicero, that Octavian was an "excellent youth who must be praised and—sent to another place," neatly expresses the popular view of the situation. Cicero was sharply criticized by M. Junius Brutus for truckling to Octavian while showing irreconcilable enmity to Antony and Lepidus (*ad Brut.* i. 16. 4, i. 15. 9); but Brutus was safe in his province, and it is difficult to see what other course was open to a politician in Rome. Whether Cicero was right or wrong, none can question his amazing energy. He delivered his long series of *Philippics* at Rome, and kept up a correspondence with the various provincial governors and commanders, all short-sighted and selfish, and several of them half-hearted, endeavouring to keep each man in his place and to elaborate a common plan of operations. He was naturally included in the list of the proscribed, though it is said that Octavian fought long on his behalf, and was slain near Formiae on Dec. 7, 43. He had a ship near in which he had previously attempted to flee, but being cast back by unfavourable winds he returned to his villa, saying, "Let me die in the country which I have often saved." His head and hands were sent to Rome and nailed to the rostra, after Fulvia, wife of Antony and widow of Clodius, had thrust a hairpin through the tongue.

Works.—The literary works of Cicero may be classed as (i.) rhetorical; (ii.) oratorical; (iii.) philosophical and political; (iv.) epistolary.

(i.) *Rhetorical.*—His chief works of this kind are: (a) *de Oratore*, a treatise in three books dedicated to his brother Quintus. The discussion is conducted in the form of a dialogue which is supposed to have occurred in 91 B.C. chiefly between the two orators L. Crassus and M. Antonius. The first book deals with the studies necessary for an orator; the second with the treatment of the subject matter; the third with the form and delivery of a speech. Cicero says of this work in a letter (*Fam.* i. 9. 23) that it "does not deal in hackneyed rules and embraces the whole theory of oratory as laid down by Isocrates and Aristotle." (b) *Brutus*, or *de claris oratoribus*, a history of Roman eloquence containing much valuable information about his predecessors, drawn largely from the *Chronicle* (*liber annalis*) of Atticus. (c) *Orator*, dedicated to M. Brutus, sketching a portrait of the perfect and ideal orator, Cicero's last word on oratory. The sum of his conclusion is that the perfect orator must also be a perfect man. Cicero says of this work that he has "concentrated in it all his taste" (*Fam.* vi. 18. 4). The three treatises are intended to form a continuous series containing a complete system of rhetorical training.

It will be convenient to mention here a feature of Ciceronian prose on which singular light has been thrown by recent inquiry. In the *de Oratore*, iii. 173 *sqq.*, he considers the element of rhythm or metre in prose, and in the *Orator* (174–226) he returns to the subject and discusses it at length. His main point is that prose should be metrical in character, though it should not be entirely metrical, since this would be poetry (*Orator*, 220). Greek writers relied for metrical effect in prose on those feet which were not much used in poetry. Aristotle recommended the pæan — — — —. Cicero preferred the cretic — — —, which he says is the metrical equivalent of the pæan. Demosthenes was especially fond of the cretic. Rhythm pervades the whole sentence but is most important at the end or *clausula*, where the swell of the period sinks to rest. The ears of the Romans were almost incredibly sensitive to such points. We are told that an assembly

was stirred to wild applause by a double trochee— $\cup\cup$.¹ If the order were changed, Cicero says, the effect would be lost. The same rhythm should be found in the *membra* which compose the sentence. He quotes a passage from one of his own speeches in which any change in the order would destroy the rhythm. Cicero gives various *clausulae* which his ears told him to be good or bad, but his remarks are desultory as also are those of Quintilian, whose examples were largely drawn from Cicero's writings. It was left for modern research to discover rules of harmony which the Romans obeyed unconsciously. Other investigators had shown that Cicero's *clausulae* are generally variations of some three or four forms in which the rhythm is trochaic. Dr. Thaddaeus Zielinski of Warsaw, after examining all the *clausulae* in Cicero's speeches, finds that they are governed by a law. In every *clausula* there is a basis followed by a cadence. The basis consists of a cretic or its metrical equivalent.² This is followed by a cadence trochaic in character, but varying in length. The three favourite forms are (i.) $\cup\cup\cup$, (ii.) $\cup\cup\cup\cup$, (iii.) $\cup\cup\cup\cup\cup$. These he styles *verae* (V). Other frequent *clausulae*, which he terms *licitae* (L), are those in which a long syllable is resolved, as in verse, into two shorts, e.g., *essē vidēātūr*. These two classes, V and L, include 86% of the *clausulae* in the orations. Some rarer *clausulae* which he terms M (= *malae*) introduce no new principle. There remain two interesting forms, viz., S (= *selectae*), in which a spondee is substituted for a trochee in the cadence, e.g., $\cup\cup\cup\cup\cup$, this being done for special emphasis, and P (= *pessimae*), where a dactyl is so used, e.g., $\cup\cup\cup\cup\cup$, this being the *heroica clausula* condemned by Quintilian. Similar rules apply to the *membra* of the sentence, though in these the S and P forms are more frequent, harmony being restored in the *clausula*.

These results apply not only to the speeches but also to the philosophical writings and the more elaborate letters, and with modifications to other rhythmical prose, e.g., that of Pliny and Seneca. Rhythm was avoided by Caesar who was an Atticist, and by Sallust, who was an archaist. Livy's practice is exactly opposite to that of Cicero, since he has a marked preference for the S forms, thereby exemplifying Cicero's saying that long syllables are more appropriate to history than to oratory (*Orator*, § 212).

(ii.) *Speeches*.—These were generally delivered before the senate or people, if political in character, and before jurors sitting in a *quaestio*, if judicial. The speech against Vatinius was an attack upon a witness under examination; that *de Domo* was made before the Pontifices; that *pro C. Rabirio perduellionis reo* in the course of a *provocatio* to the people; and those *pro Ligario* and *pro rege Deiotaro* before Caesar. The five orations composing the *Actio Secunda in Verrem* were never spoken, but written after Verres had gone into exile. The Second *Philippic* also was not delivered but issued as a pamphlet. Cicero's speech for Milo at his trial was not a success, though, as Quintilian (ix. 2. 54) quotes from it, as taken down by shorthand reporters, an example of a rhetorical figure well used, it cannot have been such a failure as is alleged by later writers. The extant speech was written by Cicero at his leisure. None of the other speeches is in the exact form in which it was delivered. Cicero's method was to construct a *commentarius* or skeleton of his speech, which he used when speaking. If he was pleased with a speech he then wrote it out for publication. Sometimes he omitted in the written speech a subject on which he had spoken. A record of this is sometimes preserved: e.g., "de Postumi criminibus" (*Mur.* 51), "de teste Fufio" (*Cael.* 19). These *commentarii* were published by his freedman Tiro and are quoted by Asconius (*ad Orat. in Toga Candida*, p. 87).

Cicero in his speeches must be given all the privileges of an

¹*Orator*, § 214: "patris dictum sapiens temeritas fili cōprobāvit"—hoc dichoreo tantus clamor contionis excitatus est ut admirabile esset. Quaero, nonne id numerus efficerit? Verborum ordinem immuta, fac sic: 'Comprobavit fili temeritas' jam nihil erit."

²This theory is partly anticipated by Terentianus Maurus (c. A.D. 290), who says of the cretic (v. 1440 sqq.):—

"Plurimum orantes decebit quando paene in ultimo
Obtinet sedem beatam, terminet si clausulam
Dactylus spondeus imam, nec trochaicum respuo;
Plenius tractatur istud arte prosa rhetorum."

advocate. Sometimes he had a bad client; he naïvely confesses the straits to which he was put when defending Scamander (*Clu.* 51; cf. *Phil.* xiii. 26). He thought of defending Catiline, though he says that his guilt is clear as noon-day (*Att.* i. 1-2 and ii. 1). Sometimes the brief which he held at the moment compelled him to take a view of facts contrary to that which he had previously advocated. Thus in the *pro Caecina* he alleges judicial corruption against a witness, Falcus, while in the *pro Cluentio* he contends that the offence was not proved (*Caec.* 28, *Clu.* 103). He says quite openly that "it is a great mistake to suppose that statements in his speeches express his real opinions" (*Clu.* 139). It is therefore idle to reproach him with inconsistencies, though these are sometimes very singular. Thus in the *pro Cornelio* he speaks with praise of Gabinius, who, when a colleague vetoed his proposal, proceeded to depose him after the precedent set by Tiberius Gracchus (Asconius in *Cornel.* p. 71). In the *pro Cluentio*, 111, he contends that nothing is easier than for a new man to rise at Rome. In the *pro Caelio* he says that Catiline had in him undeveloped germs of the greatest virtues, and that it was the good in him that made him so dangerous (*Cael.* 12-14). He sometimes deliberately puts the case upon a wrong issue. In the *pro Milone* he says that either Milo must have lain in wait for Clodius or Clodius for Milo, leaving out of sight the truth, that the encounter was due to chance. He used to boast that he had cast dust into the eyes of the jury in the case of Cluentius (*Quintil.* ii. 17-21).

Cicero had a perfect mastery of all weapons wielded by a pleader in Rome. He was specially famous for his pathos, and for this reason, when several counsel were employed, always spoke last (*Orat.* 130). A splendid specimen of pathos is to be found in his account of the condemnation and execution of the Sicilian captains (*Verr.* [Act. ii.] v. 106-122). Much exaggeration was permitted to a Roman orator. Thus Cicero frequently speaks as if his client were to be put to death, though a criminal could always evade capital consequences by going into exile. His enemies scoffed at his "tear-drops." He indulged in the most violent invective, which, though shocking to a modern reader, e.g., in his speeches against Vatinius and Piso, was not offensive to Roman taste (*de Orat.* ii. 216-290). He was much criticized for his jokes, and even Quintilian (ii. 17-21) regrets that he made so many in his speeches. He could never resist the temptation to make a pun. It must be remembered, however, that he was the great wit of the period. Caesar used to have a collection of Cicero's *bons mots* brought to him. Cicero complains that all the jokes of the day were attributed to himself, including those made by very sorry jesters (*Fam.* vii. 32. 1). A fine specimen of sustained humour is to be found in his speech *pro Murena*, where he rallies the jurisconsults and the Stoics. He was also criticized for his vanity and perpetual references to his own achievements. His vanity, however, as has been admirably remarked, is essentially that of "the peacock, not of the gander," and is redeemed by his willingness to raise a laugh at his own expense (Strachan-Davidson, p. 192). Some critics have impugned his legal knowledge, but probably without justice. It is true that he does not claim to be a great expert, though a pupil of the Scaevolae, and when in doubt would consult a jurisconsult; also, that he frequently passes lightly over important points of law, but this was probably because he was conscious of a flaw in his case.

(iii.) *Political and Philosophical Treatises*.—These are generally written in the form of dialogues, in which the speakers sometimes belong to bygone times and sometimes to the present. The first method was known as that of Heracleides, the second as that of Aristotle (*Att.* xiii. 19. 4). There is no reason to suppose that the speakers held the views with which Cicero credits them, or had such literary powers as would make them able to express such views (*ib.*, xiii. 12. 3). The political works are *de Republica* and *de Legibus*. The first was a dialogue in six books concerning the best form of constitution, in which the speakers are Scipio Africanus Minor and members of his circle. He tells us that he drew largely from Plato, Aristotle, Theophrastus and writings of the Peripatetics. The famous "Dream of Scipio" recalls the "Vision of Er" in Plato's *Republic* (Book x. *ad fin.*). The *de*

Legibus, a sequel to this work in imitation of Plato's *Laws*, is drawn largely from Chrysippus.

Cicero as a philosopher belonged to the New Academy. The followers of this school were free to hear all arguments for and against, and to accept the conclusion which for the moment appeared most probable (*Acad.* ii. 131). Thus in the *Tusculan Disputations* v. he expresses views which conflict with *de Finibus* iv., and defends himself on the ground that as an Academic he is free to change his mind. He was much fascinated by the Stoic morality, and it has been noticed that the *Tusculan Disputations* and *de Officiis* are largely Stoic in tone. He has nothing but contempt for the Epicureans, and cannot forgive their neglect of literary style. As Cicero's philosophical writings have been severely attacked for want of originality, it is only fair to recollect that he resorted to philosophy as an anodyne when suffering from mental anguish, and that he wrote incredibly fast. He issued two editions of his *Academica*. The first consisted of two books, in which Catulus and Lucullus were the chief speakers. He then rewrote his treatise in four books, making himself, Varro and Atticus the speakers. His works are confessedly in the main translations and compilations (*Att.* xii. 52. 3); all that he does is to turn the discussion into the form of a dialogue, to adapt it to Roman readers by illustrations from Roman history, and to invent equivalents for Greek technical terms. This is equally true of the political treatises. Thus, when Atticus criticized a strange statement in *de Republ.* ii. 8, that all the cities of the Peloponnese had access to the sea, he excuses himself by saying that he found it in Dicaearchus and copied it word for word (*Att.* vi. 2. 3). In the same passage he used an incorrect adjective, *Phliuntii* for *Phliasii*; he says that he had already corrected his own copy, but the mistake survives in the single palimpsest in which this work has been preserved. The only merits, therefore, which can be claimed for Cicero are that he invented a philosophical terminology for the Romans, and that he produced a series of manuals which from their beauty of style have had enduring influence upon mankind.

The most famous of these treatises are the following:

De Finibus, on the Supreme Good. In Book i. L. Manlius Torquatus explains the Epicurean doctrine, which is refuted in ii. by Cicero. In iii. and iv. M. Porcius Cato sets forth the doctrine of the Stoics which is shown by Cicero to agree with that of Antiochus of Ascalon; in v. M. Pupius Piso explains the views of the Academics and Peripatetics.

Tusculanae Disputationes, so called from Cicero's villa at Tusculum in which the discussion is supposed to have taken place. The subjects treated are:—in Book i., the nature of death and the reasons for despising it; Book ii., the endurance of pain; pain is not an evil; Book iii., wisdom makes a man insensible to sorrow; Book iv., wisdom banishes all mental disquietude; Book v., virtue is sufficient to secure happiness. The materials are drawn largely from works of Dicaearchus.

De Deorum Natura.—The dialogue is placed in 77 B.C. In Book i. Velleius attacks other philosophies and explains the system of Epicurus. He is then refuted by Cotta. In Book ii. Balbus, speaking as a Stoic, discusses the existence of the gods, nature, the government of the world and providence. In Book iii. Cotta criticizes the views of Balbus. The statement of the Epicurean doctrine is drawn from the work of Phaedrus, *περὶ θεῶν* the criticism of this from Posidonius. The Stoic teaching is derived from Cleanthes, Chrysippus and Zeno, and is criticized from the writings of Carneades and Clitomachus.

De Officiis, addressed to his son Marcus. In this the form of dialogue was not employed. The material is chiefly drawn from Stoic sources, e.g., works of Panaetius in Books i. and ii., of Posidonius and Hecato in Book iii.

The *Academica*, as they have come down to us, are a conflation from the two editions of this work. They consist of the second book from the first edition, and a portion of the first book from the second edition.

Cato maior, or *de Senectute*, a dialogue placed in 150 B.C., in which Cato, addressing Scipio and Laelius, set forth the praises of old age. The idea is drawn from Aristo of Chios, and the

materials largely derived from Xenophon and Plato.

Laelius, or *de Amicitia*, a dialogue between Laelius and his sons-in-law, in which he sets forth the theory of friendship, speaking with special reference to the recent death of Scipio. Cicero here draws from a work of Theophrastus on the same subject and from Aristotle.

(iv.) *Letters*.—Those preserved are (1) *ad Familiares*, i.-xvi.; (2) *ad Atticum*, i.-xvi.; (3) *ad Quintum*, i.-iii., *ad Brutum*, i.-ii. Some 35 other books of letters were known to antiquity, e.g., to Caesar, to Pompey, to Octavian and to his son Marcus.

The collection includes nearly 100 letters written by other persons. Thus, the eighth Book *ad Fam.* consists entirely of letters from Caelius to Cicero when in Cilicia. When writing to Atticus Cicero frequently sent copies of letters which he had received. There is a great variety in the style not only of Cicero's correspondents, but also of Cicero himself. Caelius writes in a breezy, school-boy style; the Latinity of Plancus is Ciceronian in character; the letter of Sulpicius to Cicero on the death of Tullia is a masterpiece of style; Matus writes a most dignified letter justifying his affectionate regard for Caesar's memory. Several of his correspondents are indifferent stylists. Cato labours to express himself in an awkward and laconic epistle, apologizing for its length. Metellus Celer is very rude, but gives himself away in every word. Antony writes bad Latin, while Cicero himself writes in various styles. We have such a *cri de coeur* as his few words to one of the conspirators after Caesar's murder, "I congratulate you. I rejoice for myself. I love you. I watch your interest; I wish for your love and to be informed what you are doing and what is being done" (*Fam.* vi. 15). When writing to Atticus he eschews all ornamentation, uses short sentences, colloquial idioms, rare diminutives and continually quotes Greek. This use of Greek tags and quotations is also found in letters to other intimate friends, e.g., Paetus and Caelius; also in letters written by other persons, e.g., Cassius to Cicero; Quintus to Tiro, and subsequently in those of Augustus to Tiberius. It is a feature of the colloquial style and often corresponds to the modern use of "slang." Other letters of Cicero, especially those written to persons with whom he was not quite at his ease or those meant for circulation, are composed in his elaborate style with long periods, parentheses and other devices for obscuring thought. These are throughout rhythmical in character, like his speeches and philosophical works.

We know from Cicero's own statement (*Att.* xvi. 5. 5) that he thought of publishing some of his letters during his lifetime. On another occasion he jestingly charges Tiro with wishing to have his own letters included in the "volumes" (*Fam.* xvi. 17. 1). It is obvious that Cicero could not have meant to publish his private letters to Atticus in which he makes confessions about himself, or those to Quintus in which he sometimes outsteps the limits of brotherly criticism, but was thinking of polished productions such as the letters to Lentulus Spinther or that to Lucceius which he describes as "very pretty" (*Att.* iv. 6. 4).

It is universally agreed that the letters *ad Familiares* were published by Tiro, whose hand is revealed by the fact that he suppresses all letters written by himself, and modestly puts at the end those written to him. That Cicero kept copies of his letters, or of many of them, we know from a passage in which, when addressing a friend who had inadvertently torn up a letter from him, he says that there is nothing to grieve about; he has himself a copy at home and can replace the loss (*Fam.* vii. 25. 1). Tiro may have obtained from Terentia copies of letters written to her. It has been suggested that he may also have edited the letters to Quintus, as he could obtain them from members of the family. The letters *ad Familiares* were generally quoted in antiquity by books, the title being taken from the first letter, e.g., *Cicero ad Varronem epistula Paeti*.

While the letters *ad Familiares* were circulated at once, those to Atticus appear to have been suppressed for a considerable time. Cornelius Nepos (*Att.* 16) knew of their existence but distinguishes them from the published letters. Asconius (p. 87), writing under Claudius, never quotes them, though, when discussing Cicero's projected defence of Catiline, he could hardly have

failed to do so, if he had known them. The first author who quotes them is Seneca. It is, therefore, probable that they were not published by Atticus himself, who died 32 B.C., though his hand may be seen in the suppression of all letters written by himself, but that they remained in the possession of his family and were not published until about A.D. 60. At that date they could be published without expurgation of any kind, whereas in the letters *ad Familiares* the editor's hand is on one occasion (iii. 10. 11) manifest. Cicero is telling Appius, his predecessor in Cilicia, of the measures which he is taking on his behalf. There then follows a lacuna. It is obvious that Tiro thought the passage compromising and struck it out. In the letters to Atticus, on the other hand, we have Cicero's private journal, his confessions to the director of his conscience, the record of his moods from day to day, without alterations of any kind.

Cicero's letters are the chief and most reliable source of information for the period. It is due to them that the Romans of the day are living figures to us, and that Cicero, in spite of, or rather in virtue of his frailties, is intensely human and sympathetic. The letters to Atticus abound in the frankest self-revelation, though even in the presence of his confessor his instinct as a pleader makes him try to justify himself. The historical value of the letters, therefore, completely transcends that of Cicero's other works. It is true that these are full of information. Thus we learn much from the *de Legibus* regarding the constitutional history of Rome, and much from the *Brutus* concerning the earlier orators. The speeches abound in details which may be accepted as authentic, either because there is no reason for misrepresentation or on account of their circumstantiality. Thus the *Verrines* are our chief source of information for the government of the provinces, the system of taxation, the powers of the governor. They tell us of the monstrous system by which the governor could fix upon a remote place for the delivery of corn, and so compel the farmer to compound by a payment in money which the orator does not blame, on the ground that it is only proper to allow magistrates to receive corn wherever they wish (iii. 190). From the speech *pro Cluentio* (145-154) we gain unique information concerning the condition of society in a country town, the extraordinary exemption of *equites* from prosecution for judicial corruption, the administration of domestic justice in the case of slaves examined by their owner (*ib.*, 176-187). But we have always to be on our guard against misrepresentation, exaggeration and falsehood. The value of the letters lies in the fact that in them we get behind Cicero and are face to face with the other *dramatis personae*; also that we are admitted behind the scenes and read the secret history of the times. One of the most interesting documents in the correspondence is a despatch of Caesar to his agent Oppius, written in great haste and in disjointed sentences. It runs as follows: "On the 9th I came to Brundisium. Pompey is at Brundisium. He sent Magius to me to treat of peace. I gave him a suitable answer" (*Att.* ix. 13, A). In the *de Bello civili*, on the other hand, Caesar who wishes to show that he did his best to make peace, after stating that he sent his captive Magius to negotiate, expresses mild surprise at the fact that Pompey did not send him back (*Bell. Civ.* i. 26). We hear of the extraordinary agreement made by two candidates for the consulship in Caesar's interest with the sitting consuls of 54 B.C., which Cicero says he hardly ventures to put on paper. Under the terms of this the consuls, who were *optimates*, bound themselves to betray their party by securing, apparently fraudulently, the election of the candidates while they in turn bound themselves to procure two ex-consuls who would swear that they were present in the senate when supplies were voted for the consular provinces, though no meeting of the senate had been held, and three augurs who would swear that a *lex curiata* had been passed, though the *comitia curiata* had not been convened (*Att.* iv. 18. 2). But perhaps the most singular scene is the council of three great ladies presided over by Servilia at Antium, which decides the movements of Brutus and Cassius in June 44 B.C., when Cassius "looking very fierce—you would say that he was breathing fire and sword"—blustered concerning what he considered an insult, viz., a commission which had been laid upon him to supply

corn. Servilia calmly remarks she will have the commission removed from the decree of the senate (*Att.* xv. 11. 2).

(v.) *Miscellaneous*.—It is not necessary to dwell upon the other forms of literary composition attempted by Cicero. He was a fluent versifier, and would write 500 verses in one night. Considerable fragments from a juvenile translation of Aratus have been preserved. His later poems upon his own consulship and his exile were soon forgotten except for certain lines which provoked criticism, such as the unfortunate verse:

"O fortunatam natam me consule Romam."

He wrote a memoir of his consulship in Greek and at one time thought of writing a history of Rome. Nepos thought that he would have been an ideal historian, but as Cicero ranks history with declamation and on one occasion with great *naïveté* asks Lucius Lucceius (*q.v.*), who was embarking on this task, to embroider the facts to his own credit, we cannot accept this criticism (*Fam.* vi. 2. 3).

(vi.) *Authenticity*.—The genuineness of certain works of Cicero has been attacked. It was for a long time usual to doubt the authenticity of the speeches *post reditum* and *pro Marcello*. Recent scholars consider them genuine. As their rhythmical structure corresponds more or less exactly with the canon of authenticity formed by Zielinski from the other speeches, the question may now be considered closed. Absurd suspicion has been cast upon the later speeches in *Catilinam* and that *pro Archia*. An oration *pridie quam in exilium iret* is certainly a forgery, as also a letter to Octavian. There is a "controversy" between Cicero and Sallust which is palpably a forgery, though a quotation from it occurs in Quintilian (iv. 1. 68). Suspicion has been attached to the letters to Brutus, which in the case of two letters (i. 16 and 17) is not unreasonable since they somewhat resemble the style of *suasoriae*, or rhetorical exercises, but the latest editors, Tyrrell and Purser, regard these also as genuine.

After Cicero's death his character was attacked by various detractors, such as the author of the spurious *Controversia* put into the mouth of Sallust, and the calumniator from whom Dio Cassius (xlv. 1-28) draws the libellous statements which he inserts into the speech of Q. Fufius Calenus in the senate. Of such critics, Asconius (in *Tog. Cand.* p. 95) well says that it is best to ignore them. His prose style was attacked by Pollio as Asiatic, also by his son, Asinius Gallus, who was answered by the emperor Claudius (Suet. 41). The writers of the silver age found fault with his prolixity, want of sparkle and epigram and monotony of his *clausulae*. A certain Largius Licinius gained notoriety by attacking his Latinity in a work styled *Ciceromastix*. His most devoted admirers were the younger Pliny, who reproduced his oratorical style with considerable success, and Quintilian (x. 1. 112), who regarded him as the perfect orator, and draws most of his illustrations from his works. At a later period his style fascinated Christian writers, notably Lactantius, the "Christian Cicero," Jerome and St. Augustine, who drew freely from his rhetorical writings.

(2) QUINTUS TULLIUS CICERO, brother of the orator and brother-in-law of T. Pomponius Atticus, was born about 102 B.C. He was aedile in 67, praetor in 62, and for the three following years propraetor in Asia, where, though he seems to have abstained from personal aggrandizement, his ill-temper gained him an evil notoriety. After his return to Rome, he heartily supported the attempt to secure his brother's recall from exile, and was nearly murdered by gladiators in the pay of Clodius. He distinguished himself as one of Julius Caesar's legates in the Gallic campaigns, served in Britain, and afterwards under his brother in Cilicia. On the outbreak of the Civil War between Pompey and Caesar, Quintus, like Marcus, supported Pompey, but after Pharsalus he deserted and made peace with Caesar, largely owing to the intercession of Marcus. Both the brothers fell victims to the proscription which followed Caesar's death, Quintus being put to death in 43, some time before Marcus. His marriage with Pomponia was very unhappy, and he was much under the influence of his freedman Statius. Though trained on the same lines as Marcus he never spoke in public, and even said,

"One orator in a family is enough, nay even in a city." Though essentially a soldier, he took considerable interest in literature, wrote epic poems, tragedies and annals, and translated plays of Sophocles. There are extant four letters written by him (one to his brother Marcus, and three to his freedman Tiro) and a short paper, *de Petitione Consulatus* (on canvassing for the consulship), addressed to his brother in 64. A few hexameters by him on the 12 signs of the zodiac are quoted by Ausonius.

(3) **MARCUS TULLIUS CICERO**, only son of the orator and his wife Terentia, was born in 65 B.C. At the age of 17 he served with Pompey in Greece and commanded a squadron of cavalry at the battle of Pharsalus. In 45 he was sent to Athens to study rhetoric and philosophy, but abandoned himself to a life of dissipation. It was during his stay at Athens that his father dedicated the *de Officiis* to him. After the murder of Caesar (44) he attracted the notice of Brutus, by whom he was offered the post of military tribune, in which capacity he rendered good service to the Republican cause. After the battle of Philippi (42), he took refuge with Sextus Pompeius in Sicily, where the remnants of the Republican forces were collected. He took advantage of the amnesty granted by the Treaty of Misenum (39) to return to Rome, where he took no part in public affairs, but resumed his former dissipated habits. In spite of this, he received signal marks of distinction from Octavian, who not only nominated him augur, but accepted him as his colleague in the consulship (30). He had the satisfaction of carrying out the decree which ordered that all the statues of Antony should be demolished, and thus "the divine justice reserved the completion of Antony's punishment for the house of Cicero" (Plutarch). He was subsequently appointed proconsul of Asia or Syria, but nothing further is known of his life. In spite of his debauchery, there is no doubt that he was a man of considerable education and no mean soldier, while Brutus, in a letter to his father (*Epp. ad Brutum*, ii. 3), even goes so far as to say that the son would be capable of attaining the highest honours without borrowing from the father's reputation.

(4) **QUINTUS TULLIUS CICERO** (c. 67–43 B.C.), son of Quintus Tullius Cicero (brother of the orator). He accompanied his uncle Marcus to Cilicia, and, in the hope of obtaining a reward, repaid his kindness by informing Caesar of his intention of leaving Italy. After the battle of Pharsalus he joined his father in abusing his uncle as responsible for the condition of affairs, hoping thereby to obtain pardon from Caesar. After the death of Caesar he attached himself to Mark Antony, but, owing to some fancied slight, he deserted to Brutus and Cassius. He was included in the proscription lists, and was put to death with his father in 43. In his last moments he refused under torture to disclose his father's hiding-place. His father, who in his concealment was a witness of what was taking place, thereupon gave himself up, stipulating that he and his son should be executed at the same time.

BIBLIOGRAPHY.—It is impossible to mention more than a few works as the literature is so vast. (1) *Historical.*—J. L. Strachan-Davidson, *Cicero and the Roman Republic* (Heroes of the Nations series, 1894); G. Boissier, *Cicéron et ses amis* (1865); W. Warde Fowler, *Social Life at Rome* (1908); introduction to R. Y. Tyrrell and L. C. Purser's edition of the letters (1904–18); Th. Zielinski, *Cicero im Wandel der Jahrhunderte* (3rd ed., Leipzig, 1912). (2) *Literary.*—M. Schanz, *Geschichte der römischen Literatur*, i., 194–274 (München, 1890). (3) *Linguistic.*—H. Merguet, *Lexikon zu den Schriften Ciceros* (Jena, 1887–94); J. Le Breton, *Études sur la langue et la grammaire de Cicéron* (1901); E. Norden, *Die antike Kunstprosa* (Leipzig, 1898); Th. Zielinski, "Das Clausegesetz in Ciceros Reden" in *Philologus* (Leipzig, 1904); L. Laurand, *Études sur le style des discours de Cicéron* (1907). Much information on points of Ciceronian idiom and language will be found in J. S. Reid's *Academica* (London, 1885), *de Finibus*, i.–ii. (Cambridge, 1925) and G. Landgraf's *Pro Sext. Roscio* (Erlangen, 1884). (4) *Legal.*—A. H. J. Greenidge, *The Legal Procedure of Cicero's Time* (Oxford, 1901). (5) *Philosophical.*—An excellent account of Cicero as a philosopher is given in the preface to Reid's editions of the *Academica*. (6) *Editions* (critical) of the complete texts.—Baitter-Halm (1845–61); C. F. W. Müller (1880–96); Oxford Classical Texts. (A. C. C.)

CICERO, a town of Cook county (Ill.), U.S.A., 7m. W. of the "Loop," and bounded by Chicago on the north, east, and south.

It is served by the Burlington, the Baltimore and Ohio, Chicago Terminal, the Belt of Chicago, and the Manufacturers' Junction railways. In 1900 the population was 16,310; in 1920 it was 44,995 (34.4% foreign-born white), and in 1930 it was 66,600 by Federal census. Cicero is an important industrial centre, manufacturing electrical equipment, pumps, engines, windmills, malleable iron castings and enamelled ware. The aggregate factory product in 1925 was valued at \$175,000,000. The assessed valuation of property was \$13,761,734 in 1926. Cicero was settled about 1849, and was incorporated in 1867.

CICERONE, a guide, one who conducts visitors to museums, galleries, etc., and explains matters of historic or artistic interest. The word is presumably taken from Marcus Tullius Cicero as a type of learning and eloquence. According to a quotation (1762) cited by the *New English Dictionary* the word seems first to have been applied to "learned antiquarians who show and explain to foreigners the antiquities and curiosities of the country."

CICHLID. The fishes of the family *Cichlidae* are perches with a single nostril on each side and with the lower pharyngeals coalesced or united by suture. They are found in lakes, rivers and brackish lagoons of Central and South America, Africa and Syria, Madagascar and India. This distribution was formerly considered to favour the idea of the persistence of the connection between South America and Africa into the Eocene, but the value of the Cichlids in this relation is discounted by the fact that many species enter brackish water and some the sea. Their presence in Madagascar, where none of the true freshwater African families is represented, indicates that their dispersal has been accomplished in a manner different from these.

The American species number about 250, the African 400; none of the genera is common to the two continents. The Indian *Etroplus* is an isolated genus, related only to *Paretroplus* of Madagascar, in which island the genera are peculiar, the two others being related to African genera. In the African Cichlid fauna an extraordinary diversity and specialization is attained in the great lakes, Tanganyika having 100 species, nearly all belonging to genera found only in the lake, and Nyassa having nearly as many endemic species, some of which have evolved on parallel lines to those of Tanganyika. The lacustrine genera differ from each other, especially in modifications of the mouth and teeth, enabling these fishes to make use of every kind of animal and vegetable food available in the lakes. Many Cichlids are beautifully coloured, and are favourite aquarium fishes. *Herichthys cyanoguttatus* of Mexico, covered with bright blue spots, is one of the really handsome species. *Pterophyllum scalare* of the Amazon has the body very deep and strongly compressed and the dorsal and anal fins high. *Tilapia nilotica*, the bolti of the Nile, reaches a length of 18 inches.

In many Cichlids the female fish keeps the eggs in her mouth until they hatch, and for a time swims with her brood, opening her mouth for the little fishes to swim in when danger threatens. In other species the eggs are laid in a hollow scooped out by the male; both parents guard the nest until the eggs hatch, when the mother takes the young into her mouth. (C. T. R.)

CICISBEO (chī-chis-bā'ō), the term in Italy (17th century onwards) for a dangler about women. The cicisbeo was the professed gallant of a married woman, who attended her at all public entertainments, it being considered unfashionable for the husband to be her escort.

CICOGNARA, LEOPOLDO, COUNT (1767–1834), Italian archaeologist and writer on art, was born at Ferrara. A residence of some years at Rome, devoted to the study of the antiquities and galleries, was followed by visits to Naples and Sicily. He then visited Florence, Milan, Bologna and Venice, acquiring a complete archaeological knowledge of these and other cities. In 1795 he took up his abode at Modena, and was for 12 years engaged in politics, becoming minister plenipotentiary of the Cisalpine Republic at Turin. Napoleon decorated him with the Iron Crown; and in 1808 he was made president of the Academy of the Fine Arts at Venice. In 1808 appeared his treatise *Del bello ragionamenti*. This was followed (1813–18) by his *magnum opus*, the *Storia della scultura dal suo risorgimento in Italia al*

secolo di Napoleone. The book was designed to complete the works of Winckelmann and D'Agincourt, and is illustrated with 180 plates in outline. His *Fabbriche più cospicue di Venezia*, two superb folios, containing some 150 plates, was published (1815-20) under the auspices of Francis I. of Austria. Charged by the Venetians with the presentation of their gifts to the Empress Caroline at Vienna, Cicognara added to the offering an illustrated catalogue of the objects it comprised; this book, *Omaggio delle Provincie Venete alla maestà di Carolina Augusta*, has since become of great value to the bibliophile. In 1821 he published at Pisa a *catalogue raisonné*, rich in bibliographical lore, of his fine library, the result of 30 years of loving labour, which in 1824 was purchased *en bloc* by Pope Leo XII., and added to the Vatican library. Cicognara's work in the academy at Venice, of which he became president in 1808, led to the foundation of a gallery for the reception of Venetian pictures.

See Zanetti, *Cenni biografici di Leopoldo Cicognara* (Venice, 1834); Malmani, *Memorie del conte Leopoldo Cicognara* (Venice, 1888).

CICONIIDAE: see JABIRU; STORK.

CID, THE (sid, Spanish *thêth*), Diaz de Bivar (d. 1099), the favourite hero of Spain, and the most prominent figure in her literature. The name, however, is so obscured by fable as scarcely to belong to history. The Jesuit Masdeu denies that he existed, and this heresy has not wanted followers even in Spain. The truth of the matter has been expressed by Cervantes, through the mouth of the Canon in Don Quixote: "There is no doubt there was such a man as the Cid but much doubt whether he achieved what is attributed to him."

The Cid of history is still the foremost man of the heroic period of Spain—the greatest warrior of the long struggle between Christian and Muslim, and the perfect type of the Castilian of the 12th century. Rodrigo Diaz, called de Bivar, from the place of his birth, better known by the title given him by the Arabs as the *Cid* (*El Seid*, the lord) and *El Campeador*, the champion, was born of a noble family about 1040, being first mentioned (as Rodrigo Díaz de Vivar) in a charter of Ferdinand I. of 1064. He rose to great distinction in the war between Sancho of Castile and Sancho of Navarre, in which he won his name of *Campeador* by slaying the enemy's champion in single combat. In the quarrel between Sancho and his brother Alphonso, he espoused the cause of the former, and suggested the perfidious stratagem by which Sancho eventually obtained possession of León. Sancho having been slain in 1072, while engaged in the siege of Zamora, the exiled Alphonso returned and occupied the vacant throne. The Cid accepted the new monarch, was entrusted with high commissions of State, and in 1074 married Ximena, daughter of the count of Oviedo, and granddaughter of Alphonso V. Some time afterwards he was sent to collect tribute from Motamid, the king of Seville, who was at war with Abdullah, the king of Granada. During the battle which ensued under the walls of Seville, Abdullah and his auxiliaries were routed, the Cid returning to Burgos with many prisoners and a rich booty. Garcia Ordoñez then accused him to Alphonso of keeping part of the tribute, and the king took advantage of the Cid's absence on a raid against the Moors to banish him from Castile in 1081.

Henceforth Rodrigo Diaz lived that life of a soldier of fortune which has made him famous, sometimes fighting with the Christians, sometimes with the Moors, but always for his own hand. At the head of 300 free lances he offered his services to the count of Barcelona; then, failing him, to Moktadir, the Arab king of Saragossa, under whose successors he fought for nearly eight years, against Mohammedan and Christian, being admitted almost to a share of their royal authority. His overtures towards Alphonso being rejected, he extended the Arab dominions at the expense of the Christian States of Aragon and Barcelona, and harried even the borders of Castile. Among the enterprises of the Cid the most famous was that against Valencia, where he appeared at the head of 7,000 men, chiefly Mohammedans. In defiance of a relief army, under Yusuf the Almoravide, the Cid took Valencia after a siege of nine months, on June 15, 1094—the richest prize which had been recovered from the Moors. The conditions of the surrender were all violated—the *cadi* Ibn Djahhaff burnt alive, many citizens

slaughtered, and the possessions divided among the Cid's companions. The Cid ruled his kingdom, which now embraced nearly the whole of Valencia and Murcia, for four years, with vigour and justice. At length the Almoravides defeated him at Cuenca, and the blow led to his death in July, 1099. His widow maintained Valencia against the Moors till 1102, when she evacuated the city, taking with her the body of the Cid to be buried in the monastery of San Pedro at Cardena, near Burgos. The bones have since been removed to the town hall of Burgos.

The Cid of romance is not the historical rebel, the consorter with infidels and the enemies of Spain. He is the type of knightly virtue, the mirror of patriotic duty, the flower of all Christian grace, the Roland, the King Arthur, and Bayard in one. In a barbarous Latin poem, written in celebration of the conquest of Almeria by Alphonso VII. in 1147, the bard sings of the supereminence of the Cid among his country's heroes:—

Ipse Rodericus *Mio Cid* semper vocatus,
De quo cantatur quod ab hostibus haud superatus,
Qui domuit Mauros, comites domuit quoque nostros.

The *Poema del Cid*, of the latter half of the 12th century, the oldest extant Spanish epic, written in a barbarous style, in rugged assonant rhymes, and a rude Alexandrine measure, full of a noble simplicity and a true epic grandeur, is invaluable as a living picture of the age, though it is silent about the Cid's cruelties. The ballads relating to him number nearly 200, most of which date from the 16th century and are of inferior merit. They all take very great liberties with history. Such of the ballads as are not genuine relics of the 12th century are either poetical versions of episodes in the hero's life as contained in the *Chronicle*, which itself was composed out of still earlier legends, or later inventions inspired by the romance of chivalry. In these last the ballad-mongers, not to let their hero be outdone by Amadis of Gaul and the other heroes of romance, engage him in the most extravagant adventures—making war upon the king of France and upon the emperor, receiving embassies from the sultan of Persia, or bearding the pope. The last and the worst of the Cid ballads are those which betray by their frigid conceits and feeble mimicry of the antique the false taste and unheroic spirit of the age of Philip II. The influence of the Spanish Cid cycle in France first appeared in Du Périer's novel: *La Hayne et l'Amour d'Arnoul et de Clairemonde* (1600), and more notably in Corneille's *Cid* (1636), which was greatly indebted to the drama by Guillen de Castro, *Las Mocedades del Cid* (1614?).

BIBLIOGRAPHY.—The chief sources for the story of the Cid are the Latin chronicle discovered by Risco in the convent of San Isidro at León, which appears, from internal evidence, to date from before 1258; the *Cronica General*, composed by Alphonso X. (d. 1284), partly (so far as relates to the Cid) from the above, partly from contemporary Arab histories, partly from tradition; the *Cronica particular del Cid* (first pub. 1512 by Juan de Velorado), a compilation from the last, interlarded with pious fictions; lastly, various early Arabic manuscripts, discussed in Dozy's *Recherches sur l'histoire politique et littéraire de l'Espagne pendant le moyen âge*, vol. ii. (Leyden, 1849). The *Chronicle* was translated into Eng. by R. Markham (1883), and with elaborations by Robt. Southey (1883). The last edition and translation of the *Poem of the Cid* is by A. M. Huntington (The Hispanic Socy. of America, 1921). The largest collection of the Cid ballads is that of Duran in the *Romancero general*, vol. x., xvi. of Rivadeneyra's *Biblioteca de autores españoles* (1849-51). Huber, Müller, and F. Wolf are among the authorities for the history and literature of the Cid. See also J. Fitzmaurice-Kelly, *History of Spanish Literature* (1926); H. Butler Clarke, *The Cid Campeador* (1897); Hämel, *Der Cid im Spanischen Drama* (1910).

CIDER or CYDER, as made outside of the United States, is an alcoholic beverage made from apples. It is produced by the vinous fermentation of the expressed juice of the fruit. Although any kind of apples can be used for the purpose, special vintage varieties distinguished by chemical and other characters which render them unsuited for the most part for table use are required for a beverage of fine quality. The making of cider has been attempted wherever the apple is grown extensively, but a flourishing commercial industry has hitherto been established only in those countries where true vintage fruit can be obtained.

The Cider Districts.—The cider apple orchards of the world are mainly confined to certain districts of France and England.

The former country possesses the largest acreage and ranks as the chief producing centre, its average annual output of fruit being sufficient to permit of a considerable export trade to adjacent countries after home requirements have been satisfied. The cider orchards of France are chiefly concentrated in Normandy and Brittany, where the soil and other local conditions are particularly well suited to produce fruit of a high order of vintage quality. The average annual output of cider in France for the years 1915-24 was 18.4 million hectolitres. In England, where the acreage under cider fruit is also extensive, the orchards are almost entirely confined to the western and south-western counties. The belt of country extending from the counties of Hereford and Worcester in the north and passing through Gloucester and Monmouth to Somerset and Devon in the south contains by far the greatest number of orchards. In that area, according to the returns of the Ministry of Agriculture and Fisheries, the extent of grass orcharding is approximately 100,000 ac., of which the major part is planted with cider apple trees. Cider fruit growing has also spread into the counties bordering that area. In other parts of Great Britain the cider industry is limited to a few scattered localities, of which parts of Norfolk, Suffolk and Kent are the most important. Efforts have been made to develop the industry in Ireland with some success, but in this case the quantity of fruit grown specially for the purpose is small. The cider-making industry in Germany has attained considerable dimensions, but it has been in the past to some extent dependent on supplies of imported French fruit. Of the other European countries Spain and Switzerland have obtained some repute as cider producers.

Farm Cider and Factory Cider.—While in France and Germany the cider industry has long been of considerable commercial importance and the manufacture of the beverage has been carried on in factories of some magnitude, in England prior to the beginning of the present century cider making was chiefly confined to the farms upon which the fruit was grown. The product was mainly consumed on the farm and the surplus disposed of in the immediate locality. Except for the output of a few old-established factories the distribution and consumption of cider were confined almost exclusively to the west of England. Since then there has been a remarkable change. The introduction of improved methods of making as the result of research and education has led to a marked improvement in the quality of the article placed upon the market, which has been followed by the widespread adoption of cider as a popular beverage throughout the country generally. Many new factories in the cider-making area have been established and a large part of the fruit which used to be made into cider on the farms is now sold by the farmers to the factories. There has been a gradual elimination of making on farms where the product used to be indifferently prepared, and on many of the farms where making is still practised the process now receives the skilled attention necessary.

Legal Standards.—As a commercial article English cider has been handicapped by its extreme variability in character. No legal definitions or standards have been imposed and a wide variety of types has therefore been placed upon the market. In France, where hitherto the industry has been of much greater commercial importance, cider has to conform to a series of regulations defining the respective standards of the beverage to which the name may be applied. These regulations, which came into force in 1908, lay down that no beverage may be offered for sale under the name of cider unless produced exclusively by the fermentation of the juice from fresh apples, or a mixture of fresh apples and pears extracted with or without the addition of pure water. The term *Cidre pur juice* is reserved for cider made without addition of water. The name *Cidre* may only be applied to a beverage containing at least 3.5% by volume of alcohol, actual or potential, 12 grams of dry extract at 100° C (sugar not included) per litre, and 1.2 grams of mineral matter (ash) per litre. All ciders containing smaller quantities of alcohol, extract and ash than those limits or any of them must be designated as *petite cidre*. In England, though no corresponding regulations exist, the application of the name of cider to beverages other than those of which

apple juice is the basis is an offence under the Merchandise Marks Acts, as illustrated by cases where legal proceedings have been taken successfully against the use of the name for synthetic aerated drinks flavoured with artificial apple essence. The above legal standards do not apply to the United States.

Constituents of Cider.—Even in the most strictly restricted class, that for "pure juice" cider, the French regulations permit a great elasticity in the nature of the beverage offered for sale. The primary reason for variability lies in the nature of the raw material. The more important constituents of apple juice are sugars, malic acid and tannin. Allowing for seasonal effects on composition and the kinds of apples used, and without taking account of extreme cases, the total sugar content of a freshly expressed juice may range from 6 to 20%, the acid from 0.1 to 1.25%, and the tannin from 0.05 to 0.75%. Further, since the extent of the ensuing fermentation is determined by the nitrogenous content of the juice, which also varies widely, it proceeds in some cases till the whole of the sugar is fermented (unless prevented by special treatment), and in others ceases prematurely and leaves more or less of the sugars unfermented. According to the nature of the juice used, therefore, the finished article may be sweet or dry, strongly or very lightly alcoholic, highly acid or of a very low grade of acidity, and strongly astringent and bitter or almost entirely lacking in that character.

The variations here indicated are attributable primarily to the varieties of apples from which the juice is derived. By a suitable blending of different sorts, juices of any desired standard of composition can be secured. In practice individual makers aim at definite standards suited to the taste of their customers and some degree of uniformity is thus attained: but since the predominating kinds of apples grown in different areas vary widely, and other local influences, such as those of soil and climate, come into play, the ciders of different districts tend to show marked distinctive local characters. French ciders generally are characterized by low acidity and a "bittersweet" flavour. Those of the English cider area north of Bristol are usually light and brisk as compared with the typical heavy sub-acid and bittersweet Somerset ciders and the less heavy but luscious Devon type of rather low acidity and astringency.

Classification of Cider Apples.—The varieties of cider apples are grouped into three classes, commonly termed "sharp," "sweet" and "bittersweet" respectively. The classification is based upon chemical composition. The "sharp" class includes all varieties yielding the juices which normally contain not less than 0.45% of total acid, expressed as malic acid. The latter is the predominating acid, but various other organic acids are also present in very small amounts. Varieties of the "sweet" class are characterized by juices containing normally less than 0.45% of total acid, expressed as malic acid, and also less than 0.2% of "tannin." "Bittersweet" apples contain normally in their juices acids in corresponding amount to those of the "sweet" class, and are specially characterized by a relatively large quantity of "tannin," which normally exceeds 0.2%. The term "tannin" is used comprehensively by cider makers to include a group of constituents giving an astringent and bitter flavour to the juice. Chemically they may not all be true tannins.

According to this classification all table varieties of apples, dessert and culinary, fall within the "sharp" class and form a distinct section of it characterized by an extremely low "tannin" content, which rarely exceeds 0.1% in the juice. The typical "sharp" vintage apple contains generally a substantially larger amount. This high-acid, low-tannin character of the eating apple and other features usually associated with that type of composition render it inferior for cider making. The number of varieties of cider apple occurring in the orchards of England and France is very large, certainly running into thousands. Many are of very low vintage quality and are being eliminated gradually in favour of those proved by research and experience to be worthy of more extended cultivation. A complete list of the latter is too lengthy for inclusion here, but the following selection is representative of the better English and French varieties.

English varieties: *Sharp*: Cap of Liberty, Cherry Pearmain, Kingston Black, Old Foxwhelp, Yellow Styre, Skyrme's Kernel, Backwell Red, New Foxwhelp, Ponsford and Dymock Red. *Sweet*: Woodbine, Eggleton Styre, Sweet Alford, Killerton Sweet and Sweet Coppin. *Bittersweet*: Belle Norman, Chisel Jersey, Dabinett, Royal Wilding, Strawberry Norman, Yarlington Mill Jersey, Knotted Kernel, Silver Cup, White Close Pippin and Royal Jersey. French varieties: Bedan des Parts, Binet Rouge, Reine des Pommes, Doux Amer, Ecarlatine, Frequin Rouge, Amère de Berthecourt, Reinette Obry, Muscadet, Michelin and Tardive Forestier.

Cider Making.—Modern methods of cider making differ greatly from those of a century ago. Then the fruit was crushed to a pulpy mass by heavy revolving stone rollers in a circular stone trough, similar to a mortar mill, and the pulp transferred by shovels to a clumsy wooden press worked by hand, the time occupied in milling and pressing a single lot of fruit often extending over 24 hours. The modern grater form of mill now in general use is a steel cylindrical revolving drum in which are fixed toothed knives in such fashion that their edges project about one-sixteenth of an inch above the surface of the drum. The latter is power-driven at 2,000 revolutions a minute. The fruit falling upon it is grated almost instantaneously to a very fine pulp, from which owing to its extreme state of disintegration the juice can be expressed with great ease and speed. This pulp, technically termed "pomace," is delivered from the mill direct on to the bed of the press, where it is built up into a "cheese," consisting of a series of layers, each wrapped in an open-meshed cloth or net of cotton or other strong fibre and separated from its neighbours by slatted wooden racks to facilitate the drainage of the juice. Power-driven hydraulic presses have now largely superseded the old screw-type. With machinery of this type the whole series of operations can be completed within 20 minutes after the delivery of the fruit to the mill. With fruit in good condition, a yield of juice varying from 75 to 80% of weight of the fruit can be obtained.

Juice extracted by this method is comparatively clear and free from fragments of pulp and can therefore be placed directly into fermenting vats or casks without any intervening treatment being required to remove the suspended solid matter. The operation of "keiving," formerly an important stage in the clearing of the juice, is thus no longer necessary and the risk of taint from acetic fermentation greatly reduced.

Subsequent treatment is determined by the type of cider to be produced. If a sweet cider is required, the fermenting juice must be filtered at a comparatively early stage to make it possible to retain the desired percentage of unfermented sugar. If a dry cider is wanted, fermentation is allowed to proceed till the whole or the greater part of the sugar is converted into alcohol: filtration is then required for the purpose of clarifying the liquor rather than for checking fermentation. Various types of filters are in use: they differ in constructional details rather than in principle, which consist in the forcing under pressure of the turbid liquor through a thick layer of paper pulp or other suitable fibrous material. In many cases a single filtration suffices to clear the cider to a brilliant condition: occasionally for sweet ciders a second filtration is necessary to prevent further fermentation.

After filtration the cider is fit for consumption at any time, though age, within limits, brings improvement in flavour. Made by the process here outlined, cider generally requires filtration within three months of the time of milling and is in its best condition for consumption during the summer following making. Specialized forms of treatment are sometimes practised for the production of a more fully matured article, which may require two or three years to reach prime condition.

In some factories a diffusion process, analogous to that used in the extraction of sugar from sugar-beet, is substituted for that of direct expression of the juice by pressure already described.

Cider "Disorders" and Preservatives.—Attempts have been made to eliminate the risks of various bacterial disorders by pasteurization of the freshly expressed juice and subsequent

fermentation by added pure cultures of selected kinds of yeasts and some measure of success has been achieved. Most makers, however, still adhere to the older method of natural fermentation resulting from the wild yeasts naturally present on the surface of the apples and rely on strict attention to cleanliness at all stages of production to minimize the risks of disorders. The practice of washing the fruit in running water prior to milling is being increasingly adopted to ensure the maximum of cleanliness.

The chief disorders to which cider is subject are acetification, ropiness and "sickness," each due to specific micro-organisms, and discoloration, attributable generally to contamination with iron. To check fermentation and prevent the development of bacterial disorders preservatives such as salicylic acid were formerly largely used. Under the regulations relating to the use of preservatives in foods and drinks which came into force in Great Britain in 1927 no preservative other than sulphur dioxide is permissible for cider. The maximum allowed is 14 grains of free and combined sulphur dioxide per gallon. Preservatives as controlled in the United States are described below.

The wholesome properties of pure cider are widely recognized. In affections of a gouty or rheumatic nature positive benefit frequently results and regular cider drinkers are rarely troubled by stone, gravel and similar disorders. The malic acid of cider is regarded as a powerful diuretic which stimulates the kidneys and prevents accumulation of uric acid within the system.

The improved position of the cider industry and the marked developments in technique have been greatly assisted by the researches and educational work on the subject conducted in France at the *Station pomologique* at Caen, in Germany and Switzerland at the research stations of Geisenheim-am-Rhein and Wädenswil respectively, and in England at the National Fruit and Cider Institute established at Long Ashton, near Bristol, and now associated with Bristol university.

Warcollier, "Pomologie et cidricerie" in G. Wery, *Encyclopédie Agricole* (1920). (B. T. P. B.)

UNITED STATES

The consumption of unfermented apple juice, "sweet cider," in America, according to the U.S. Department of Agriculture, probably exceeds that of all other beverage juices. Confusion exists regarding the word "cider" applied, as it has been, to fermented and unfermented juices. In 1928 "cider" was widely used in the United States to refer to the unfermented juice, distinct from English and French practice. This article will not discuss "hard cider," a fermented product which is prohibited by law, except under special conditions. The wide-spread character of cider-making as a farm industry outlet for surplus fruit is shown by the 1922 average production per farm, which was very nearly 100 gallons. Apples are widely grown in the United States, but sweet cider is virtually a seasonal product, usually consumed within a few days after the apple harvest. It is practically unobtainable after the pressing season except in small quantities sold through soda fountains and stores. This is due largely to the failure of small-scale producers of apple juice to practice pasteurizing so as to make their product available for use in a sweet condition at any season. Various chemical preservatives have been more or less used to prevent fermentation, but are entirely unnecessary if the juice is properly pasteurized and sealed. However, benzoate of soda, under certain conditions may be employed under the food and drug act.

To pasteurize, on a small scale, place the filled bottles in an ordinary tin wash boiler on a false bottom or rack, submerging in cold water, thus allowing circulation. In the boiler lid make a small hole to admit a long-stemmed thermometer so hung that the bulb is within two or three inches of the boiler bottom. On a larger scale, for handling big jugs or carboys, use a tight wooden box, preferably with a lid to keep in the steam, and lined with soldered sheet iron or copper to prevent leaks, with a steam heating coil, a slatted rack to support the containers and a reliable

thermometer to permit temperature control. Satisfactory heating is gained by the use of waste steam, running a perforated exhaust pipe into the box beneath the false bottom and allowing the steam to escape into the water, which must cover the containers completely, to keep them at a temperature of 175° F for at least ten minutes; then they are allowed to cool slowly without exposure to the air.

To prepare unfermented apple juice, select sound, well-matured, properly ripened fruit. If different varieties are available at the same time, blend to give balanced, well-flavoured cider. Wash and sort the fruit, trimming or discarding all specked or partially decayed apples; grind and press, subsequently repressing the pomace; place the juice in deep containers in a cool room overnight, and allowing the settling out of the pomace, siphon off the juice from the sediment.

In attempts to produce juices relatively free from sediment and fairly uniform in appearance, various combinations of two or more treatments have been used in the United States. The most satisfactory of these composite methods for ordinary home use (method I.) is as follows: Place the juice in sterilized containers, seal with sterilized tops and submerge in cold water in the pasteurizer. Bring the temperature up to 175° F and keep it at that point for the prescribed time. Then store until the coagulum produced by heating has been settled, decanted or siphoned off and passed through a pulp filter, milk separator or centrifuge, if available. Place in the final containers and again pasteurize. While this method gives very satisfactory results, it is time-consuming and labourious; the juice must be twice pasteurized, requiring storage space and extra containers, considerable loss resulting from fermentation and repeated handling.

Another process (method II.) which combines several desirable features makes the entire process of preparation of the juice, from pressing the fruit to pasteurization of the juice in the final containers, practically continuous, eliminates the necessity of pasteurizing the juice and holding it in storage containers for clearing, lessens the loss from breakage and cost of production and enables the maker to put the finished product on the market within a few days after pressing begins. At the same time it produces a clear sediment-free fluid without the use of costly special equipment and without the loss of the characteristic flavour and quality of the juice. Allow the juice to stand for about 12 hours to settle, decant from the sediment and blend if necessary. Transfer to suitable vessels, mix with diatomaceous earth (also called infusorial earth, kieselguhr and diatomite) at the rate of 6 to 8 lb. per 100 gal., thoroughly stirred to prevent sliming and clogging, when filtered through a thin layer of diatomaceous earth supported by a closely woven cloth. Prepare filter by passing a suspension of diatomaceous earth in water through a filter press or bag filter so as to form a thin layer of earth on the filter cloth. The clear juice is placed in the final containers as it comes from the filter, sealed and pasteurized, which completes the work. Store the juice in a cool, dark room until settled for two weeks to four months.

The number of apple varieties cultivated is so large and the various apple-growing districts differ so widely that no complete picture can be given here. More than 164,000,000 bu. of apples were produced in the United States in 1925. The most important apples in the usual American cider-making classes are—sweet sub-acid: Baldwin, Esopus, Hubbardston, Fameuse, McIntosh, Northwestern, Rome Beauty and Stark; acid: Winesap, Jonathan, Yellow Newton, Stayman Winesap, Northern Spy and York Imperial; aromatic: Delicious, Golden Delicious, Lady, Black Gilliflower, White Pearmain and Banana Bonum; astringent: Florence, Hibernial, Soulard, Red Siberian, Hyslop, Transendent, Launette, Martha and Yellow Siberian; neutral: Ben Davis, Black Ben, Gana, Willowtwig, Missouri, Alexander, Wolf River, Buckingham and Limbertwig.

Blending of two or more varieties is necessary to obtain high-grade unfermented juice, which should have a characteristic apple flavour, plus tannin, sugar and acid, in definite ratio to one another. Winesap is one of the few juices not improved by modifica-

tion of the acid or sugar content. If tannin is high, as in many crab apples, the juice is harsh and astringent; if too acid, the flavour is sour; too much sugar tastes insipid, lacking in sprightliness. Furthermore, apples vary greatly in the amount of characteristic flavour they possess. Therefore, selection and blending cannot be done too carefully in order to obtain the desired result. The prospective manufacturer of cider should consult the latest government regulations, regarding State and Federal control.

CIENFUEGOS (originally FERNANDINA DE JAGUA), one of the principal cities of Cuba, in Santa Clara province, near the central portion of the southern coast, 195 m. E.S.E. of Havana. Pop. (1925 census) 73,480. Cienfuegos is served by the United States railways of Havana and by steamers connecting with Santiago de Cuba, Batabanó, Trinidad and the Isle of Pines. It lies about 6 m. from the sea on a peninsula in the magnificent landlocked bay of Jagua. Vessels drawing 16 ft. have direct access to the wharves. The city is lighted by gas and electricity, has an abundant water supply, and cable connection with Europe, the United States, the other Antilles and South America. The surrounding country is one of the prettiest and most fertile regions in Cuba, varied with woods, rivers, rocky gulches, beautiful cascades and charming tropic vegetation. Several of the largest and finest sugar estates in the world are situated in the vicinity, including the Soledad (with a botanical experiment station maintained by Harvard University) the Terry and others—most of them connected with the city by good driveways. Cienfuegos is a centre of the sugar trade on the south coast; tobacco too is exported.

The bay of Jagua was visited by Columbus. The city was founded in 1819, with the aid of the Spanish government, by a Louisianian, Gen. Luis de Clouet. The settlement was first named in honour of Ferdinand VII., and later in honour of Capt. Gen. José Cienfuegos Jovellanos. The harbour was known from the earliest times, and has been declared by Mahan to be the most important of the Caribbean sea for strategic purposes. In 1740-41 a fortification called Nuestra Señora de los Angeles was erected at the entrance; it is still standing, on a steep bluff overlooking the sea, and is one of the most picturesque of the old fortifications of the island. On May 11, 1898, a force from two vessels of the U.S. fleet under Admiral Schley, searching for Cervera and blockading the port, cut two of the three cables here (at Point Colorado, at the entrance of the harbour), and for the first time in the Spanish-American War the American troops were under fire.

CIEZA, a town of south-eastern Spain, in the province of Murcia, on the Madrid-Cartagena railway, and junction for a branch to Villena. Pop. (1920) 13,684. Cieza stands on the right bank of the river Segura, in a narrow bend of the valley, which is enclosed on the north by mountains, providing good building stone and low timber, and on the south broadens into a fertile plain, producing grain, wine, olives, raisins, esparto, oranges and other fruits. The district has greatly developed with improved communications in the last 50 years and Cieza is a flourishing modern town with flour, paper, sawmilling industries and brandy distilleries.

CIEZA DE LEÓN, PEDRO DE (c. 1519-1560), Spanish soldier and historian, was born at Seville. He sailed for the New World, possibly in Heredia's expedition of 1532, more probably with Duran in 1534, reaching Cartagena in November. In 1535 he went with Heredia's brother Alonzo to Darien, and in 1538 with Vadillo on an appalling journey up the valley of the Cauca; Vadillo was eventually deserted by his men, and Cieza de León later joined Jorge de Robledo, who consolidated the discoveries in the Cauca valley, and on his death served under Belalcázar, governor of Popayan, who had beheaded Robledo. It was in 1541, in the Cauca valley, that he started his diary. In 1547 the troops from Popayan marched to join President Gasca against Pizarro, a long journey, the details of which he carefully noted. In 1549 he went to look at the mines of Porco and Potosí, and then to Cuzco to confer with a surviving descendant of the Incas; in 1550 he left for Spain. The first part of his *Crónica de Perú* was published at Seville in 1553.

The scheme of his *Crónica de Perú* was as follows: part I., geography; part II., early history; part III. (lost), conquest; and

part IV. (of which books 1, 2 and 3 have been found), civil wars. The first part is a minute topographical review, founded on his diary, with an account of the customs and religion of the people as he found them, given with unusual accuracy of observation and without concealing his respect for the Inca civilization. Part II., referred to inaccurately by Prescott as *Sarmiento*, gives the history of Peru under the Incas. The ms. was preserved in the Escorial library and published in 1880.

C.I.F., in commerce, a short form of "cost, insurance, freight." Thus, if an article is quoted C.I.F. London it means that the quotation is inclusive of (1) the price of the article, (2) the cost of insurance to London and (3) the cost of freight to London. In the official trade returns of the United Kingdom the import values are usually recorded by the customs statistical department at C.I.F. values.

CIGAR, the primitive cigar was merely a few leaves of tobacco rolled together between the palms of the hands, one end of the roll being placed in the mouth, the other end being lit. No evidence exists to show that cigar manufacture was carried on commercially in Great Britain before 1840. In that year a small business of the kind was started; it soon began to flourish, for several cigar manufacturers displayed their products in the Great Exhibition held in London in 1851. In the first twenty years of their manufacture cigars were made in a straight shape. About 1860 the "bellied" form of cigar became popular, and in order to facilitate its production the use of a wooden "mould" was adopted. The more expert makers, however, soon came to make cigars without the use of a mould, hence the term "hand-made cigar." Cigar-making is an art which can be acquired only after some years of patient labour.

How Cigars Are Made.—In all its essentials, cigar-making is largely the same process in Havana, in Great Britain, or wherever else cigars are made, but the cigar makers of Havana and other tobacco producing regions have a great advantage over those who work imported tobacco; they have the leaf in its original moisture and are thereby enabled to manipulate it easily. In Great Britain and other European countries the leaf is bone-dry when imported and it has to be moistened in order to make it supple. After manufacture cigars have to be dried, either by exposure to the sun or by artificial means, and in this process the original curing is to some extent spoiled, and so is the aroma. Hence the proved superiority of the "native-made" cigar. Assuming, then, the suppleness of the leaf, the first process of manufacture is to strip the mid-rib or stalk from the leaf. (The stalks are afterwards ground into snuff.) The leaf is then graded into wrappers, "bunch wrappers" and fillers. The best leaves are used for wrappers, or outer covers, the next best for "bunch wrappers" and the small leaves and broken pieces are used to make up the inside of the cigars, or "fillers." In the U.S. the wrapper, binder and filler grades are usually separate products, grown in different localities; e.g., a Connecticut broadleaf wrapper, a Wisconsin binder and a Havana filler may be employed.

The operatives sit at tables at which the leaf is cut to shape and at which the cigars are rolled. The working tools of the craft are a knife with which to cut the wrappers, a pair of scissors with which to trim the leaf, and a cutter gauge with which to cut off the lighting end of a cigar at the required point, so as to make all the cigars of the same brand exactly the same length. The maker arranges in his left hand a sufficient number of pieces of filler, places them on a piece of bunch wrapper, rolls the filler into the bunch and puts the whole on one side to await the outer wrapper. The cutting of the "outer" calls for great care in order to secure that the side-veins in the leaf run straight up and down the cigar. A cigar showing round or spiral veins is a sign of poor workmanship. The outer wrapper is rolled round the cigar from the lighting end or "tuck," and the point is gummed down with a tasteless and colourless gum. In making a moulded cigar the worker presses the "filler" into a turned wooden mould (*citola*) of the exact form and size required and with a hole through which each cigar can be drawn. When the workman has made 100 cigars they are sent to the foreman for inspection, and by him to the sorter, who grades and packs them in boxes, cabinets or bundles. The cigar-maker's

occupation is a monotonous one, and in the factories at Havana a trained reader is appointed to each room. It is his (or her) duty to read aloud from newspapers and books for the edification and instruction of the operatives.

How to Know a Good Cigar.—The comparative value and merit of the many varieties of cigars can be learned only by experience. To judge a cigar, first examine it as to colour and texture. Generally, though not invariably, the lighter the colour the milder the cigar. This is not a correct assumption, however, in the case of some low priced cigars where a light coloured wrapper is used to bind a "strong" filler. The texture may be judged by the "silkeness" of the outer wrapper or leaf. The smoother the cigar feels to the touch the better, for the soft, silky touch indicates that the finest leaf has been used in its manufacture. A rough wrapper indicates a less choice cigar. Next look at the "curl" and the edges of the wrapper for gummy matter. Signs of excretion of this matter indicates poor workmanship; the edges of the wrapper should adhere firmly without showing any excretion. Then light the cigar to determine aroma and to produce ash. Aroma is always a matter for the smoker's own fancy, while the colour of the ash is important. As a rule a white ash indicates good tobacco, while a grey ash is generally the sign of inferior tobacco. The colour of the ash, however, is not an infallible test and should not alone be depended upon. Regular burning is an indispensable quality, whatever the colour of the ash. The last test is made by flicking off the ash and examining the glowing point. If the cigar is good the point will be sharp; in fact, the finer the point the better the cigar. In regard to colour, texture and age there is no ideal cigar, because every smoker's ideal is attained by the appeal which a particular brand may make to his palate and to his sense of smell. Thus one man's ideal may be a strong cigar, both as to flavour and aroma, while another may prefer a smoke of mild flavour and elusive aroma.

The darker and richer the leaf, the longer cigars require to be kept to attain maturity. Light coloured cigars lose their flavour in about six years. Dark cigars retain their natural characteristics for about ten years.

At first the only decoration of cigars was the name of the maker burned into the lid of the box, but unscrupulous dealers used to fill boxes bearing a superior brand with cigars of inferior merit. Manufacturers then pasted on each cigar a small label or ticket bearing the name of the brand, but soon smokers complained that in removing the ticket they also removed part of the cigar wrapper, or that if they left the ticket in its place it was not possible to smoke the cigar beyond the paper, or half the length of the cigar. Thus it happened that the cigar "ring" or "band" came into use. In recent years the best classes of cigars, those coming from Havana, have been packed in cedar cabinets, a method which serves to retain the true flavour of the tobacco leaf. The cedar cabinets vary in size from those containing 50 cigars to those holding 10,000.

Origin.—The cigar had its origin in the Spanish West Indies, and this gave rise to the almost universal use of the Spanish language on cigar labels and boxes. Even Continental and British cigars were sometimes labelled "Havana" and the practice became so harmful to the genuine product that in 1907 the Union of Cuban Cigar Manufacturers and Importers instituted legal proceedings in a number of countries to compel the discontinuance of the use of the Spanish language or Spanish pictures on boxes of cigars of non-Cuban origin. A certain measure of success was achieved, but some courts ruled that as the use of Spanish was universal as regards description it was not illegal to impress boxes with a brand name in Spanish. The use of Spanish trade terms to denote colour, size and shape was also held to be unobjectionable. Nevertheless, it is an offence against British statute law to apply the description "Havana" or "Habana" to any cigar not actually made in Cuba. In Havana city are the warehouses and factories of the makers of all the celebrated brands. The leaf is grown in all parts of the district by planters who take their produce into the city and sell it in the open market. Their crops are not always good. Generally speaking, there is a "vintage" crop about every four or five years. Climatic influences have much to

do with the crops, but much depends also upon the way in which the leaf is cured. Curing is effected by fermentation, of which there are two methods. Undoubtedly, the reasons why Havana cigars are best is that the climate and soil of Cuba is peculiarly suited to the growth of the leaf and that the cigars are manufactured in their "native air." Only the finest grades of leaf are used in the manufacture of Havana cigars. Americans do not, as a rule, smoke dry cigars. They prefer new or "green" cigars, a description which has no reference to colour.

Next in importance to Havana cigars come Mexican, but these have no particular virtue of flavour or aroma. It was, in fact, the substitution of Mexican for Havana cigars which led to the labelling precautions, already referred to, adopted by Havana manufacturers. Although Mexican cigars do not approach the Havana product in quality they "smoke sweet" and therefore compete with the lower Havana grades.

Considerable quantities of Mexican tobaccos are imported into England for use as "wrappers" of British-made cigars, the "fillers" of which are blended from other growths. Manila cigars formerly held a large sale in the United Kingdom; they were known as "cheroots"—a miniature form of cigar for which there is not now a large demand. Much of the Manila tobacco shipped to England is re-exported to the Continent of Europe for manufacture. Indian cigars are generically described as "Trichinopoly," after the town of that name (where they are made) in the Dindigul district of the Presidency of Madras. As a rule they are too strong in flavour for European smokers and are rarely purchased except by Anglo-Indians.

British cigars are made mainly of wrappers of Havana leaf specially imported for the purpose. The "fillers" are composed of blends of leaf from other sources. The industry is seated mainly in London and at Nottingham, although there are cigar factories in other parts of the country. Continental cigars, by which is meant cigars made in Holland, Germany and Belgium are made under a process similar to the British. That is to say, the same kinds of leaf tobacco are used, but for some reason difficult to define Continental goods are in the main not so satisfactory as British, for they are vastly inferior in flavour and are usually much cheaper.

The volume and value of the trade in imported cigars in Great Britain and Northern Ireland are indicated in the annual report of the Customs and Excise Department for the financial year ended March 31, 1927. It is shown that imports of cigars in that year, mainly from Havana, totalled 590,752lb., upon which the State received revenue amounting to £450,194. The rate of import duty on foreign cigars is 15s. 7d. per lb. The duty on cigars of Empire origin is five-sixths of the full rate. No reliable figures are available of the extent of manufacture of cigars in Great Britain or of the number of persons engaged therein.

(F. W. D.)

CIGARETTE, a small cigar consisting of fine-cut tobacco wrapped in paper. In Great Britain the tobacco mostly used is light Virginia. The leaf is first slightly damped to make it pliable, is then stripped from the stalk, or midrib, and afterwards is placed in a cutting machine which shreds it. The cut tobacco is dried in pans or stoves to remove any excess moisture and to bring out its aroma. The person making his own cigarettes takes a paper of requisite size, places upon it the desired quantity of tobacco, rolls the paper between the fingers and fastens the cigarette by moistening one edge of the paper. In the manufacture of hand-made cigarettes the "sheath" or paper is rolled into a cylinder and the edge stuck down or "crimped" by machinery. Next the tobacco is rolled into a small piece of parchment, one end of which is inserted into the sheath. The operative, using a pencil-shaped stick, then pushes the tobacco from the parchment into the sheath, the excess protruding at each end being afterwards trimmed off with scissors. If the cigarette is to be "tipped" with cork or gold leaf, this is done afterwards by girls.

Cigarette Machinery.—Recently devised machines are capable of turning out over 50,000 cigarettes per hour. The cigarette paper is in the form of a large roll of tape. It is fed into a narrow trough at the side of the machine, where the name of the brand is

printed on each cigarette length. It next passes under a funnel, which distributes the hair-like cuts of tobacco upon it. The paper passes a device by which one of the edges is gummed, and then the paper is automatically folded over the tobacco. This endless cigarette passes under a knife which cuts it into sections of the desired length.

Folding and Packing.—The principal part of the packing machine consists of a revolving disc, or tray, on which the four necessary actions are performed. The cigarettes fed into the machine first fall on to a travelling band in fives, and an instant later five other cigarettes are superimposed on them. The ten cigarettes are carried on the band to the disc, where the shaped inner case receives them. The disc turns, and stops for an instant in front of a small steel arm which plucks a cigarette card from a reservoir and lays it on the cigarettes. The disk makes a quarter revolution, when an outer cover (which is already gummed together but folded flat) falls from a receptacle into place and opens out; and on the next quarter turn the inner case containing the ten cigarettes and the card is pushed into it. The packets are then taken away to be wrapped in parcels.

Volume of Sales.—In Great Britain and in most North European countries the Virginia cigarette is mostly, if not almost exclusively, used. During the World War there was a remarkable increase of smoking among women, with whom it is still popular.

Fifty years ago cigarettes were used in England only by foreigners or those who had lived abroad. In those days Turkish or Egyptian tobacco was used, but on account of the high cost of these varieties they were never popular nor widely used. The genuine Turkish tobacco leaf is the choicest aromatic leaf in the world, but it is very expensive. Frequently tobacco grown in Greece, Macedonia, Bulgaria, China and Japan was added, but these blends were so unlike genuine Turkish tobacco that they

DIAGRAM SHOWING GROWTH OF MANUFACTURE OF ORDINARY SIZED CIGARETTES SINCE 1915 IN THE UNITED STATES

never attained wide use. Egyptian cigarettes are really made of Turkish tobacco mixed with a rather pungent native leaf called "Ayasalook." This variety can only be used for blending. There are various qualities or blends of Egyptian cigarettes. Unlike cigars, they gain nothing from being manufactured in their "native" moisture, and as a result some Egyptian cigarettes are made in Great Britain. But the trade is by no means large, for Virginia tobacco has almost displaced both Turkish and Egyptian cigarettes. Certain quantities of cigarettes are imported by Great Britain from America, Algeria and Havana, but they are not largely in demand. Havana cigarettes are made from the small broken pieces of leaf from the cigar-makers' benches.

Cigarettes do not improve with age. After two or three months they become chippy and dry, and have no flavour. The natural moisture of tobacco ranges from 15 to 17%, and it is increased to 30% in manufacture. In 1904, at the instance of the then Chancellor of the Exchequer, the maximum moisture limit in manufactured tobacco was fixed by British law at 32%, at which figure it still stands. (F. W. D.)

AMERICAN CIGARETTES

According to figures compiled in 1927 by the Internal Revenue department at Washington, revenue stamps for cigarettes were sold to cover over 97 billion cigarettes for sale in the United States. Of this number over 90% were "blended."

Blended Cigarettes.—Since about 1917 there has been a growing tendency for the American cigarette-consuming public to prefer the blended cigarette to cigarettes made from one specific type of tobacco. Cigarettes made from Virginia or Turkish tobaccos were at one time used to a very large extent in the United States, and there is still a demand for the straight Turkish cigarette by the foreign population in the large centres.

Four predominant types of tobaccos are used in American cigarettes. *Burley* is grown in the State of Kentucky and also in the territory adjacent to this State, *e.g.*, Tennessee, Ohio, Indiana and West Virginia. Until ten years ago, the *Burley* type of tobacco was used almost exclusively for chewing and pipe smoking tobaccos. For several years the use of *Burley* in blended cigarettes has shown a steady increase, the lighter bodied grades being used in conjunction with other types.

Virginia tobacco is grown in large quantities in the States of Virginia, North Carolina, South Carolina and (in later years) in Georgia. The growing of this tobacco in the U.S. goes back several hundred years.

Oriental, or Turkish tobacco, is of an entirely different type from the tobaccos grown in the United States, and has distinctive characteristics and flavour.

Maryland tobacco, grown in the State of Maryland, is used to a small extent in cigarettes.

Subjecting *Burley* tobacco to heat eliminates the harshness characteristic to this type of leaf. Great care is taken in proportioning the various types to make a mild, full flavoured cigarette.

The popular package of twenty cigarettes is first wrapped in

BY COURTESY OF THE AMERICAN MACHINE AND FOUNDRY CO.

STANDARD AUTOMATIC CIGARETTE MACHINE, CAPABLE OF TURNING OUT MANY THOUSANDS OF CIGARETTES AN HOUR

paper backed foil and this is enclosed in another pack. Some packages are further wrapped in glassine paper. The development of this package, and the automatic machinery necessary to handle it, has been the most important development of the industry.

(J. A. Cro.)

CIGNANI, CARLO (1628–1719), Italian painter, was born at Bologna, where he studied under Battista Cairo, and afterwards under Francesco Albani. Though an intimate friend of the latter and his most famous disciple, Cignani was yet strongly and deeply influenced by the genius of Correggio. His greatest work, the "Assumption of the Virgin," round the cupola of the church of the Madonna della Fuoca at Forlì, is in some respects one

of the most remarkable works of art of the 17th century, and is obviously inspired from the more renowned fresco of Correggio in the cupola of the cathedral of Parma. He removed to Forlì, where he died in 1719. His most famous pictures, in addition to the Assumption, are: the "Entry of Paul III. into Bologna"; the "François I. Touching for King's Evil"; a "Power of Love," painted under a fine ceiling by Agostino Carracci, on the walls of a room in the ducal palace at Parma; an "Adam and Eve" (at The Hague); and two of "Joseph and Potiphar's Wife" (at Dresden and Copenhagen). His son Felice (1660–1724) and nephew Paolo (1709–64) were also painters.

CIGOLI or CIVOLI, LODOVICO CARDI DA (1559–1613), Italian painter, architect and poet, was born at Cigoli in Tuscany. Educated under Alessandro Allori and Santi di Tito, he formed a peculiar style by the study at Florence of Michelangelo, Correggio, Andrea del Sarto and Pontormo. While in Florence he painted an "Ecce Homo," in competition with Passigiani and Caravaggio, which gained the prize. This work was afterwards taken by Bonaparte to the Louvre, and was restored to Florence in 1815. Other important pictures are—a "St. Peter Healing the Lame Man," in St. Peter's at Rome; a "Conversion of St. Paul," in the church of San Paolo fuori le Mura, and a "Story of Psyche," in fresco, at the Villa Borghese; a "Martyrdom of Stephen," a "Venus and Satyr," a "Sacrifice of Isaac," and a "Stigmata of St. Francis," at Florence. He died, it is said, of grief at the failure of his last fresco (in the Roman church of Santa Maria Maggiore).

CILIA, in biology, the thread-like processes by the vibration of which many lowly organisms move through water. They are also found on certain cells of both lower and higher organisms to create a current, *e.g.* on the gill of oysters, the lining of the bronchioles of the lungs in man. The singular is cilium.

CILIATA, one of the divisions of Infusoria (*q.v.*) characterized by the permanent possession of cilia or organs derived from these (membranelles, etc.), and all parasitic. They are the most highly differentiated Protozoa (*q.v.*).

CILICIA, a district of Asia Minor, extending along the south coast between Pamphylia and Syria. Its northern limit was the crest of Mt. Taurus. It was divided into Cilicia Trachea and Cilicia Pedias.

Cilicia Trachea is a rugged mountain district formed by the spurs of Taurus, which often terminate in rocky headlands with small sheltered harbours—a feature which, in classical times, made the coast a resort of pirates, and, in the middle ages, led to its occupation by Genoese and Venetian traders. The district is watered by the Geuk Su (Calycadnus), and is covered to a large extent by forests, which supply timber to Egypt and Syria. There were several towns but no large trade centres.

Cilicia Pedias included the rugged spurs of Taurus and a large plain of rich stoneless loam. Its eastern half is studded with isolated rocky crags, which are crowned with the ruins of ancient strongholds, and broken by the low hills that border the plain of Issus. The plain is watered by the Cydnus (Tarsus Chai), the Sarus (Sihun) and the Pyramus (Jihun), and is extremely productive. Through it ran the great highway, between the east and the west, on which stood Tarsus on the Cydnus, Adana on the Sarus; and Mopsuestia (Missis) on the Pyramus. The great highway from the west, on its long rough descent from the Anatolian plateau to Tarsus, ran through a narrow pass between walls of rock called the Cilician Gate (Ghulek Boghaz). After crossing the low hills east of the Pyramus it passed through a masonry (Cilician) gate, Demir Kapu, and entered the plain of Issus. From that plain one road ran southward to Alexandretta, and thence crossed Mt. Amanus by the Syrian Gate, to Antioch and Syria; and another ran northwards and crossed Mt. Amanus by the Amanian Gate, to North Syria and the Euphrates. By the last pass, which was apparently unknown to Alexander, Darius crossed the mountains prior to the battle of Issus. Both passes are short and easy, and connect Cilicia Pedias with Syria rather than with Asia Minor. In Roman times Cilicia exported the goat's-hair cloth, *cilicium*, of which tents were made.

Under the Persian empire Cilicia was apparently governed by

tributary native kings, who bore a name or title graecized as Syennesis; but it was officially included in the fourth satrapy by Darius. Xenophon found a queen in power, and no opposition was offered to the march of Cyrus. Alexander found the gates open when he came down from the plateau in 333 B.C., and it may be inferred that the great pass was not under direct Persian control. After Alexander's death it fell to the Seleucids, who, however, never held effectually more than the eastern half. Cilicia Trachea became the haunt of pirates, who were subdued by Pompey. Cilicia Pedias became Roman territory in 103 B.C., and the whole was organized by Pompey (64 B.C.) into a province, of which at one time Cicero was governor. It was reorganized by Caesar (47 B.C.), and about 27 B.C. became part of the province Syria-Cilicia-Phoenice. Under Diocletian (c. A.D. 297), Cilicia, with the Syrian and Egyptian provinces, formed the Diocesis Orientis. In the 7th century it was invaded by the Arabs, who held the country until it was reoccupied by Nicephorus II. in 965.

The Seljuk invasion of Armenia was followed by an exodus of Armenians southwards, and in 1080 there was founded in the Cilician Taurus a small principality, which gradually expanded into the kingdom of Lesser Armenia. This Christian kingdom—situated in the midst of Muslim states, hostile to the Byzantines, giving valuable support to the crusaders, and trading with the great commercial cities of Italy—had a stormy existence of about 300 years. When Levond V. died (1342), John of Lusignan was crowned king as Gosdantin IV.; but he alienated the Armenians by attempting to make them conform to the Roman Church, and at last the kingdom, a prey to internal dissensions, succumbed (1375) to the attacks of the Egyptians. Cilicia Trachea was occupied by the Osmanlis in the 15th century, but Cilicia Pedias was only added to the empire in 1515.

From 1833 to 1840 Cilicia formed part of the territories administered by Mohammed Ali of Cairo, who was compelled to evacuate it by the allied powers. By the treaty of Sévres (*see* TURKEY) part of Cilicia was granted to France, but on Oct. 20, 1921, after unsuccessful conflicts with the Nationalist troops, the French withdrew all claim to this area.

CILLI (Slovene *Celje*), a town of Slavonia, Yugoslavia, on a branch of the Zagreb-Fiume railway, lies picturesquely with remains of walls and towers on the river Sann, on an important road north to Marburg (Maribor) on the Austrian frontier and south to Ljubljana. Pop. (1921) 7,754. Probably a Celtic settlement, the Romans took it (15 B.C.) and Claudius made it a Roman municipium (A.D. 50), naming it Claudia Celeja. It prospered greatly, and its temple of Mars was widely famed. Its museum contains many Roman remains, and the Roman sewage system was rediscovered in the second half of the 19th century and is now in use. It was incorporated with Aquileia under Constantine, and was destroyed by Slavs at the end of the 6th century. The counts of Cilli, at one time in authority in Croatia, at another in Bosnia, had their castle, Ober Cilli, on the Schlossberg (1,320ft.), south-east of the town. Its ruins, the Cilli throne and the family tomb remain. Under the Cilli (1350–1455) the town prospered; on their extinction it became subject to Austria. The fine church (14th century) has a beautiful chapel and is justly renowned. The so-called German church (Romanesque) belonged to the Minorite monastery (founded 1241, closed 1808). Antimony and zinc are mined near by, and enamelled iron utensils are made. Ten miles north-west are the baths and ruined castle of Neuhaus, since 1643 called Schlagenburg.

See E. Glautschnigg, *Cilli und Umgebung; Handbuch für Fremde* (Cilli, 1887).

CILLI, ULRICH, COUNT OF (1406–1456), son of Frederick II., count of Cilli, and Elizabeth Frangepan. About 1432 he mar-

ried Catherine, daughter of George Brankovich, despot of Serbia.

His influence in the troubled affairs of Hungary and the Empire, of which he was made a prince by the emperor Sigismund (1436) led to feuds with the Habsburgs, the overlords of Cilli. Finally he made an alliance with the Habsburg king Albert II., and after his death (1439) Ulrich took up the cause of his widow, Elizabeth, and presided at the coronation of her infant son Ladislaus V. Posthumus (1440). A feud with the Hunyadis followed, embittered by John Hunyadi's attack on George Brankovich of Serbia (1444) on his refusal to recognize Ulrich's claim to Bosnia on the death of Stephen Tvrtko (1443). In 1446 Hunyadi, then governor of Hungary, harried the Cilli territories in Croatia-Slavonia; but his power was broken at Kosovo (1448), and Count Ulrich was able to lead a successful crusade, nominally in the Habsburg interest, into Hungary (1450). In 1452 he forced the emperor Frederick III. to hand over the boy king Ladislaus V. to his keeping, and became thus virtual ruler of Hungary, of which he was named lieutenant by Ladislaus in 1456. The Hunyadis now conspired to destroy him. On Nov. 8, in spite of warnings, he entered Belgrade with the king; the next day he was attacked by Laszlo Hunyadi and his friends, and put to death. With him died the male line of the counts of Cilli.

CIMA, GIAMBATTISTA (CIMA DE CONEGLIANO c. 1459–1517), Italian painter of the Venetian school, probably a pupil of Bartolomeo Montagna, and later influenced by Giovanni Bellini. He was born at Conegliano on the southern slopes of the Alps. His earliest dated picture is the altarpiece of 1489 in the Museo Civico of Vicenza. He was then 30 years old and his style is fully developed and altered very little during the course of his long life. In 1492 he settled in Venice. In 1493 he was commissioned to paint an altarpiece for the cathedral of Conegliano which is still in its original place. Most of his important works are in Venice in the churches of S. Giovanni in Bragora, S. Maria dell'Orto, the Carmine, and in the Academy; there are also pictures by him at Bologna, Modena and Parma and in many of the great galleries in Europe.

See V. Botteon, *Ricerche intorno alla vita e alle opere di G. Cima* (1893); R. Burckhardt, *Cima da Conegliano* (1905).

CIMABUE, name of a Florentine painter Cenni di Pepo active in the 13th and the beginning of the 14th century. Some Italian painters preceded Cimabue—particularly Guido of Siena and Giunta of Pisa; but though he worked on much the same principle as they, and to a like result, he was held up to admiration as the "Father of Italian Painting" by Florentine writers, inspired by local patriotism. There is no documentary evidence that a single picture attributed to Cimabue was painted by him.

His fame rested chiefly on a colossal "Madonna and Child with Angels," the largest altarpiece produced up to that date, which was painted in tempera for the chapel of the Rucellai in St. Maria Novella, Florence; but recent research has proved this work to be by the Siennese Duccio.

Among paintings still extant attributed to Cimabue are the following:—In the Uffizi in Florence, a "Madonna and Child," with eight angels, and some prophets in niches—better than the Rucellai picture in composition and study of nature, but more archaic in type, and the colour now spoiled (this work was painted for the Badia of St. Trinita, Florence); in the National Gallery, London, a "Madonna and Child with Angels," which came from the Ugo Baldi collection, and had probably once been in the church of St. Croce, Florence; in the Louvre, a "Madonna and Child," with twenty-six medallions in the frame, originally in the church of St. Francesco, Pisa. In the lower church of the Basilica of St. Francesco at Assisi, Cimabue, succeeding Giunta da Pisa, is said to have adorned the south transept—painting a colossal "Virgin and Child between four Angels," above the altar of the Conception, and a large figure of St. Francis. In the upper church, north transept, he has the "Saviour Enthroned and some Angels," and, on the central ceiling of the transept, the "Four Evangelists with Angels." It is, however, impossible to say whether Cimabue was at Assisi or not.

In the closing years of his life he was appointed capomaestro of the mosaics of the cathedral of Pisa, and was afterwards,

hardly a year before his death, joined with Arnolfo di Cambio as architect for the Cathedral of Florence. In Pisa he executed a Majesty in the apse—"Christ in glory between the Virgin and John the Evangelist," a mosaic, now much damaged. This was probably the last work that he produced.

He was the master of Giotto, whom (is the tradition) he found a shepherd boy of ten, in the pastures of Vespignano, drawing with a coal on a slate the figure of a lamb. Cimabue took him to Florence, and instructed him in the art; and after Cimabue's death Giotto occupied a house which had belonged to his master in the Via del Cocomero. Another painter with whom Cimabue is said to have been intimate was Gaddo Gaddi.

Giovanni Cimabue was buried in the cathedral of Florence, St. Maria del Fiore, with an epitaph written by one of the Nini:

Credidit ut Cimabos picturae castra tenere,
Sic tenuit vivens; nunc tenet astra poli.

Here we recognize distinctly a parallel to the first clause in the famous triplet of Dante:

Credette Cimabue nella pintura
Tener lo campo; ed ora ha Giotto il grido,
Si che la fama di colui' oscura.

CIMAROSA, DOMENICO (1749-1801), Italian musical composer, was born at Aversa, in the kingdom of Naples, Dec. 17, 1749. His parents were poor, but anxious to give their son a good education, and after removing to Naples they sent him to a free school connected with one of the monasteries of that city. He obtained a free scholarship at the musical institute of Santa Maria di Loreto, where he remained for eleven years, studying chiefly the great masters of the old Italian school. Piccini, Sacchini and other musicians of repute are mentioned amongst his teachers. At the age of twenty-three Cimarosa began his career as a composer with a comic opera called *Le Stravaganze del Conte*, first performed at the Teatro dei Fiorentini at Naples in 1772. The work met with approval as did its successors *Le Pazzie di Stellananza e di Zoroastro*, a farce full of humour and eccentricity, and another comic opera called *L'Italiana in Londra*. From 1784-87 Cimarosa lived at Florence, and wrote the following works for the theatre of that city:—*Caio Mario*; the three biblical operas, *Assalonne*, *La Giuditta* and *Il Sacrificio d'Abramo*; also *Il Convito di Pietra*; and *La Ballerina amante*, a pretty comic opera first performed at Venice with enormous success.

About the year 1788 Cimarosa went to St. Petersburg (Leningrad) by invitation of the empress Catherine II. In 1792 he went to Vienna at the invitation of the emperor Leopold II. Here he produced his masterpiece, *Il Matrimonio segreto* which ranks amongst the highest achievements of light operatic music. In 1793 he returned to Naples, where *Il Matrimonio segreto* and other works were received with great applause. Amongst the works belonging to his last stay in Naples may be mentioned the charming opera *Le Astuzie femminili*, which during recent years has been adapted with great success as one of the productions of the Diaghilev Ballet.

This period of his life is said to have been embittered by the intrigues of envious and hostile persons, amongst whom figured his old rival Paisiello. During the occupation of Naples by the troops of the French Republic, Cimarosa joined the Liberal party, and on the return of the Bourbons, was, like many of his political friends, condemned to death. By the intercession of influential admirers his sentence was commuted into banishment. But his health was broken, and after much suffering he died at Venice Jan. 11, 1801, of inflammation of the intestines. The nature of his disease led to the rumour of his having been poisoned by his enemies, which, however, a formal inquest proved to be unfounded.

CIMBALON: see DULCIMER.

CIMBRI, a Teutonic tribe which in 113 B.C. defeated the consul Gnaeus Papirius Carbo near Noreia. They had been

wandering along the Danube for some years, warring with the Celtic tribes on either bank. After the victory of 113 B.C. they passed westwards over the Rhine, threatening the territory of the Allobroges. Their request for land was not granted, and in 109 B.C. they defeated the consul Marcus Junius Silanus in southern Gaul, but did not at once follow up the victory. In 105 B.C. they returned to the attack under their king, Boiorix, and annihilated the Roman armies at Arausio (Orange). Again the victorious Cimbri turned away from Italy, and, after attempting to reduce the Arverni (q.v.), moved into Spain, where they failed to overcome the desperate resistance of the Celtiberian tribes. In 103 B.C. they marched back through Gaul, which they overran as far as the Seine, where the Belgae made a stout resistance. Near Rouen the Cimbri were reinforced by the Teutoni and two cantons of the Helvetii. They marched southwards by two routes, the Cimbri moving on the left towards the passes of the eastern Alps, while the newly arrived Teutoni and their allies made for the western gates of Italy. In 102 B.C. the Teutoni and Ambrones were totally defeated at Aquae Sextiae by Marius, while the Cimbri succeeded in passing the Alps and driving Q. Lutatius Catulus across the Adige and Po. In 101 B.C. Marius overthrew them on the Raudine Plain near Vercellae. Their king, Boiorix, was killed, and the whole army destroyed. The Cimbri were the first in the long line of the Teutonic invaders of Italy.

The original home of the Cimbri has been much disputed. From information gained from the *Monumentum Ancyranum* and the map of Ptolemy, it may reasonably be conjectured that they came from the peninsula of Jutland, where their name may be preserved in Himmerland (Aalborg). Strabo and other early writers related a number of curious facts concerning the customs of the Cimbri, which are of great interest as the earliest records of the manner of life of the Teutonic nations.

Perrin (1920); Strabo, *Geography*, Bk. VII. i. and ii., with Eng. trans., H. L. Jones (1917-27), both in the Loeb Classical Library; Ptolemy, *Geography*, Bk. II. xi., ed. O. Cuntz (1923). For *Monumentum Ancyranum* see ANCYRA.

CIMICIFUGA, in botany, a small genus of herbaceous plants, of the family Ranunculaceae, comprising 12 species widely distributed in the north temperate zone. Bugbane (*C. foetida*) is used as a preventive against vermin; and the root of the North American black snake-root (*C. racemosa*) as an emetic.

CIMINIA, VIA, an ancient road of Italy, which diverged from the Via Cassia at Sutrium, and led along the east side of the Lacus Ciminius (Macaulay's "Ciminian mere," mod. Lago di Vico, an extinct crater basin) out of which it climbed on the north to 2,785 feet. Thence it descended and rejoined the Via Cassia at Aquae Passeris, a few miles north of Viterbo. The Ciminian hills are still wooded, and of great beauty. Caprarola on the east slopes of the crater, contains a very fine palace built for Alessandro Farnese in 1547-59 by Vignola, with the interior decorated by the Zuccari brothers; other villages in the district (notably Soriano with the Palazzo Chigi, which also has a fine castle of 1278), also contain good specimens of his architecture; while S. Martino al Cimino has a fine French Gothic 13th century church.

See S. Bargellini, *I Monti del Cimino* (Bergamo, *Arti Grafiche*, 1914, well illustrated).

CIMMERII, an ancient people of the far north or west of Europe, first spoken of by Homer (*Odyssey*, xi. 12-19), who describes them as living in perpetual darkness. Herodotus (iv. 11-13), in his account of Scythia, regards them as the early inhabitants of South Russia (after whom the Bosphorus Cimmerius [q.v.] and other places were named), driven by the Scyths along by the Caucasus into Asia Minor, where they maintained themselves for a century. But it is quite possible that some Cimmerii made their raids across the Hellespont, having been cut off by the Scyths as the Alani (q.v.) were by the Huns. Certain it is that in the middle of the 7th century B.C., Asia Minor was ravaged by northern nomads (Herod. iv. 12), one

body of whom is called in Assyrian sources *Gimirrai* and is represented as coming through the Caucasus. They were probably Iranian speakers, to judge by the few proper names preserved. The name has also been identified with the biblical Gomer, son of Japheth (Gen. x. 2, 3). Later writers identified them with the Cimbri of Jutland, who were probably Teutonized Celts, but this is a mere guess due to the similarity of name.

For the Cimberian invasions described by Herodotus, see SCYTHIA; LYDIA; GYGES.

CIMON (c. 507–449 B.C.), Athenian statesman and general, was the son of Miltiades (q.v.) and Hegesipyle, daughter of the Thracian prince Olorus. Cimon's first task in life was to pay the fine (about £12,000) which had been imposed on Miltiades after the Parian expedition. After winning a high reputation in the second Persian invasion, he served under Aristides with the Athenian fleet and later (477, see *Camb. Anc. Hist.*, vol. v. App. B) became sole commander. His first success was the expulsion of Pausanias from Byzantium. Having captured Eion (at the mouth of the Strymon), he expelled the Persian garrisons from the entire seaboard of Thrace with the exception of Doriscus, and, having captured Scyros (470), confirmed his popularity by transferring thence to Athens the supposed bones of Theseus. In 466 Cimon proceeded to liberate the Greek cities of Lycia and Pamphylia, and at the mouth of the Eurymedon he defeated the Persians decisively by land and sea.

The Persian danger was now over, and the immediate purpose of the Delian League was achieved. Already, however, Athens had introduced the policy of coercion which was to transform the league into an empire, a policy which, after the ostracism of Themistocles and the death of Aristides, must be attributed to Cimon, whose fundamental idea was the union of the Greeks against all outsiders (see DELIAN LEAGUE). Carystus was compelled to join the league; Naxos (c. 469) and Thasos (465–463), which had revolted, were compelled to accept the position of tributary allies. In 464 Sparta was in difficulties, owing to the revolt of her Helots. Cimon persuaded the Athenians to send aid, on the ground that Athens could not "stand without her yoke-fellow" and leave "Hellas lame." The expedition was a failure, and Cimon was attacked by the democrats led by Ephialtes. The history of this struggle is not clear. The ordinary account is that Ephialtes during Cimon's absence in Messenia overthrew the Areopagus (q.v.) and then obtained the ostracism of Cimon, who tried to reverse his policy. It may be pointed out that when the Messenian expedition started, Cimon had twice within the preceding year triumphed over the opposition of Ephialtes, and that presumably the Cimonian party was predominant until after the expedition proved a failure. It is therefore unlikely that, immediately after Cimon's triumph in obtaining permission to go to Messenia, Ephialtes was able to attack the Areopagus with success. The chronology would thus be: ostracism of Cimon, spring, 461; fall of the Areopagus, summer, 461.

A more difficult question is involved in the date of Cimon's return from ostracism. The ordinary account says that he was recalled after Tanagra (457) to negotiate the Five Years' Truce (451 or 450). Some writers, maintaining that Cimon did return soon after 457, say that the truce which he arranged was really the four months' truce recorded by Diodorus (only). To this there are two main objections: (1) if Cimon returned in 457, why does the evidence of antiquity connect his return specifically with the truce of 451? and (2) why does he after 457 disappear for six years and return again to negotiate the Five Years' Truce and to command the expedition to Cyprus? It seems much more likely that he returned in 451, at the very time when Athens returned to his old policy of friendship with Sparta and war against Persia (i.e., the Cyprus expedition).

Cimon died in Cyprus (449), and was buried in Athens. Later Attic orators speak of a "Peace" between Athens and Persia, which is sometimes connected with the name of Cimon and sometimes with that of Callias. If any such peace was concluded, it cannot have been soon after the battle of the Eurymedon as Plutarch assumes. It can have been only after the evacuation of Cyprus (i.e., c. 448). There are weighty reasons which render

it improbable that any formal peace can have been concluded at that period between Athens and Persia (see further Ed. Meyer's *Forschungen*, ii.).

Cimon's services in consolidating the empire rank with those of Themistocles and Aristides. He is described as genial, brave and generous. The one great principle for which he is memorable is that of the balance of power between Athens and Sparta, as respectively the naval and military leaders of a united Hellas. It has been the custom to regard Cimon as a man of little culture. The truth is that, as in politics, so in education and attitude of mind, he represented the ideals of an age which, in the new atmosphere of democratic Athens, seemed to savour of rusticity and lack of education.

BIBLIOGRAPHY.—The lives of Cimon by Plutarch and Cornelius Nepos are uncritical; the conclusions above expressed are derived from a comparison of Plutarch, *Cimon*, 17, *Pericles*, 10; Theopompus, frag. 92; Andocides, *de Pace*, §§ 3, 4; Diodorus xi. 86 (the four months' truce). See histories of Greece (e.g., Grote, ed. 1907), *Cambridge Ancient History*, vol. v., c. ii. and iii.; also PERICLES; DELIAN LEAGUE, with works quoted.

CIMON OF CLEONAE, an early Greek painter, who is said to have introduced great improvements in drawing. He represented "figures out of the straight, and ways of representing faces looking back, up or down; he also made the joints of the body clear, emphasized veins, worked out folds in garments" (Pliny).

CINCH, a Mexican saddle girth; figuratively, a secure hold.

CINCHONA, the generic name of a number of trees which belong to the family Rubiaceae. Botanically the genus includes trees of varying size, some reaching a height of 80 ft. and upwards, with evergreen leaves and deciduous stipules. The flowers are arranged in panicles, white or pinkish in colour, with a pleasant odour, the calyx being five-toothed superior, and the corolla tubular, five-lobed and fringed at the margin. The stamens are five, almost concealed by the tubular corolla, and the ovary terminates in a fleshy disk. The fruit is an ovoid or subcylindrical capsule, splitting from the base and held together at the apex. The numerous seeds are flat and winged all round. About 40 species have been distinguished, but of these not more than about a dozen have been economically utilized. The plants are natives of the western mountainous regions of South America, their geographical range extending from 10° N. to 22° S. lat.; and they flourish generally at an elevation of from 5,000 to 8,000 ft. above sea-level, although some have been noted growing as high as 11,000 ft., and others down to 2,600 feet.

The trees are valued solely on account of their bark, which long has been the source of the valuable febrifuge or antipyretic medicine, quinine (q.v.). The earliest well-authenticated instance of the medicinal use of cinchona bark is found in the year 1638, when the countess of Chinchon (hence the name), the wife of the governor of Peru, was cured of an attack of fever by its administration. The medicine was recommended in her case by the corregidor of Loxa, who was said himself to have practically experienced its supreme virtues eight years earlier. A knowledge of the bark was disseminated throughout Europe by members of the Jesuit brotherhood, whence it also became generally known as Jesuits' bark. According to another account, this name arose from its value having been first discovered to a Jesuit missionary who, when prostrate with fever, was cured by the administration of the bark by a South American Indian. In each of the above instances the fever was no doubt malaria.

The bark was formerly procured by cutting down the trees, which grew isolated or in small clumps in the dense forests of New Granada, Ecuador, Peru and Bolivia. Cultivation was first tried in Algeria, but failed. Later, in 1854, the Dutch Government fitted out an expedition to South America and obtained several hundred trees which were planted in Java. A British expedition to the Andes in 1859 brought back trees which were planted in Ceylon and India. The cultivation was at first on a large scale and very successful in Ceylon, but the decrease in price of quinine and the attacks of disease caused it to be given up there. The plantations of Java have now almost the monopoly, though a considerable amount is grown in India. The bark of several species is employed for the extraction of the alkaloids quinine, cinchon-

idine and cinchonine, e.g., *C. succirubra*, *C. calisaya*, *C. cordifolia*, *C. officinalis* and *C. Sedgeriana*.

CINCHONA BARK, ALKALOIDS OF. About 30 distinct alkaloids have been isolated from cinchona bark, of which quinine is by far the most important, followed by quinidine, cinchonidine and cinchonine. Owing to the therapeutic importance of cinchona bark and its four principal alkaloids most of the National Pharmacopeias prescribe methods of estimating these constituents in the bark and lay down standards both for the bark and for quinine. Thus the British Pharmacopeia requires that red cinchona bark should yield from 5% to 6% of alkaloids, of which not less than half must consist of quinine and cinchonidine, and for quinine sulphate a test is prescribed which excludes all but a minimum quantity of cinchona alkaloids, other than quinine. (For further information see ALKALOIDS.)

Quinine, $C_{20}H_{24}O_2N_2$.—This alkaloid is rarely seen or used, except in the form of its salts with acids. Though it contains two atoms of nitrogen it behaves as a monoacidic base yielding a sulphate of the formula $(C_{20}H_{24}O_2N_2)_2, H_2SO_4, 7H_2O$, popularly known as "quinine." It crystallizes in bulky masses of colourless, glistening needles, which become dull on exposure to air owing to the loss of five of their molecules of water of crystallization, so that the thoroughly, stable, air-dry salt has the composition $(C_{20}H_{24}O_2N_2)_2, H_2SO_4, 2H_2O$. It is sparingly soluble in water, more so in alcohol and still more in a mixture of alcohol and chloroform. The solutions are laevorotatory and those in water, especially when acidified, are strongly fluorescent. Two other sulphates, $C_{20}H_{24}O_2N_2, H_2SO_4, 7H_2O$ (so-called disulphate) and $C_{20}H_{24}O_2N_2, 2H_2SO_4, 7H_2O$ (so-called tetra-sulphate) are known and are used when more soluble salts are required. Quinine hydrochloride $C_{20}H_{24}O_2N_2 HCl, 2H_2O$, which closely resembles the ordinary sulphate in appearance but has the advantage of being a little more soluble in water, is also in use. In addition, a great variety of special salts have been made in attempts to combine the therapeutic advantages of quinine with those of medicinally valuable acids, e.g., quinine salicylate, acetylsalicylate, valerianate, cacodylate, etc.

On reduction quinine furnishes hydroquinine, which also occurs in cinchona bark and is the raw material for the production of a series of drugs in which the side-chains of quinine are modified to enhance its therapeutic properties in certain directions. The best known of these modified cinchona alkaloids is "eucupin."

Quinidine, $C_{20}H_{24}O_2N_2$ (also called conquinine). This alkaloid, which is a dextrorotatory isomeride of quinine, crystallizes from alcohol in colourless prisms and melts when dry at $171.5^\circ C$. It forms two series of salts analogous with those of quinine.

Cinchonine $C_{19}H_{22}O N_2$.—This alkaloid crystallizes from alcohol in rhombic prisms and melts at $264^\circ C$. It is dextrorotatory in solution and like the other cinchona alkaloids yields two series of salts with acids.

Cinchonidine, $C_{19}H_{22}O N_2$.—This laevorotatory isomeride of cinchonine (see above), is one of the chief constituents of the mixture of alkaloids present in red cinchona bark, the variety now generally produced for making galenical preparations of cinchona. It crystallizes from alcohol in large colourless prisms, melting at $207^\circ C$, and corresponds with quinine in being laevorotatory in solution, but is unlike it in showing no fluorescence in dilute sulphuric acid. It forms two series of salts, analogous with those of quinine described above.

These four cinchona alkaloids have been the subject of investigations designed to determine their constitution and permit of their synthesis, almost continuously since they were discovered in 1820. The reactions of the four alkaloids indicate that they can all be represented by the following general formula due to Rabe (1909) and based on that of König (1906), which represents them as containing a quinoline (left) and a quinuclidine (right) nucleus, joined by a secondary alcohol group. The chemical differences between the two pairs (1) quinine and quinidine and (2) cinchonidine and cinchonine, depend on the fact that in the first pair R is the group $-OCH_3$ and in the second pair R is a hydrogen atom. In all four alkaloids R' is the group $CH:CH_2$ which can either be oxidized to a carboxyl group $-COOH$, giving

rise to a new alkaloid from each of the four, or can be reduced to CH_2-CH_3 giving rise also to four new alkaloids (hydro-quinine, hydro-cinchonine, etc.). These eight new alkaloids can in turn each produce series of new derivatives, some of which are of special interest since in them the therapeutic properties of the parent alkaloids seem to be enhanced at least in certain directions.

Further it should be noted that there is now some reason to believe that the protozoocidal action of these alkaloids, to which is due their value in malaria, is associated mainly with the quinoline nucleus, whilst their action on the heart, which has led to the use of quinidine in cardiac therapeutics, is due to the quinuclidine nucleus, since sparteine, which also contains this nucleus, is stated to exert a similar action. (See also QUININE.) (T. A. H.)

CINCINNATI, a city and the county seat of Hamilton county, O., U.S.A. $39^\circ 6' N.$, $84^\circ 30' W.$, on the north bank of the Ohio river, opposite the mouth of the Licking, about 100 m. S.W. of Columbus, about 305 m. by rail S.E. of Chicago, and about 760 m. (by rail) W.S.W. of New York. Through the city flows Mill creek, to the east the Little Miami; and to the west the Great Miami empties into the Ohio. Population, 1920, 401,247; 1930, 451,160, a gain of 49,913 or 12.4% against 37,656, 10.4% in the preceding decade. Of the 1920 population 10.7% were foreign born, 48.5% of foreign stock and 7% coloured. German is the most important foreign element. In addition to the large number of inhabitants of German descent, there were, in 1900, 107,152 of German parentage, and of the foreign born 38,219 came from Germany. At present over 90% are American born. Previous census reports were: (1810) 2,540; (1820) 9,642; (1830) 24,831; (1840) 46,338; (1850) 115,435; (1860) 161,044; (1870) 216,239; (1880) 225,139; (1890) 296,908; (1900) 325,902; (1910) 363,591.

Cincinnati is on two plateaux—one about 60 ft., the other 100–150 ft., above low water—and on hills (400 to 460 ft.) which enclose these terraces on three sides. The city datum is 546.9 ft. above sea-level, zero river gauge 430.06 ft., low water mark 431.96 feet. The low water record is 1.9 ft. (Sept. 1899) and high water 71.1 ft. (on Feb. 1884). About half the plain (average above sea-level 550 ft.) lies south of the Ohio in Kentucky and here are Covington suburbs. Cincinnati has a river frontage of about 27 m., extends back about 6 m. on the west side in the valley of Mill creek and occupies a total area of 72.2 sq.m. In 1867 it was connected with Covington by a bridge (1,056 ft. long between towers, in all 3,284 ft.). Two bridges lead to Newport; one (Cincinnati Southern railway) to Ludlow; and one to West Covington. On the terraces the streets generally intersect at right angles, but on the hills, irregularly. In the "bottoms" are the manufacturing and wholesale districts; these are spreading to the higher levels and suburbs. The principal retail houses are on the higher levels north of Third street. Most of the finer residences are on picturesque hills in the city; but there is a tendency towards more remote and larger estates. The model town, Mariemont, constructed as an entity with complete public service systems, has an extensive population. Two inclined plane railways, Mt. Adams (268 ft.) and Price hill (350 ft.) afford transportation and excellent panoramic views. Average summer temperature is 75.63° ; autumn, 56.87° ; winter, 34.37° ; spring, 54.07° ; the yearly average, 55.23° . The birth rate is 21.6 and death rate 16.6 per thousand. The wind velocity is 7 m. per hour.

Buildings.—Brick, blue limestone, and a greyish buff freestone are the common building materials. The U.S. Government building, city hall, county courthouse and the Soldiers', Sailors' and Pioneers' building (1907) are monumental structures. St. Peter's (Roman Catholic) cathedral (begun 1839) is in Greek style with a graceful stone spire 224 ft. high; it has as an altar piece Murillo's "St. Peter Liberated by an Angel." The church of St. Francis de Sales, the First (1835) and Second Presbyterian (1872), Central Christian, St. Paul's Methodist Episcopal (1870), St. Paul's Protestant Episcopal pro-cathedral (1851), Christ's Church, First Church of Christ and the Jewish Temples are notable among the 400 churches. Cincinnati is the seat of a Roman Catholic archbishopric and a Protestant Episcopal and Methodist Episcopal bishopric. The Union Central building, an

adaptation of Italian Renaissance (495 ft.) is visible for many miles. The Masonic temple, Chamber of Commerce building, Queen City club, Druggists' and Doctors' buildings and Cincinnati club are important new structures. The buildings of the Fifth-Third-Central Trust company, First and Second National banks, Provident Savings Bank and Trust company and Western and Southern Life, The Dixie terminal, Enquirer, Southern Railway, Telephone, Traction, Mercantile library, Temple Bar and Young Women's Christian association buildings are other notable modern structures. In many manufacturing plants industrial requirements are being combined with artistic expression. The amount expended for new buildings in 1927 was over \$37,000,000.

Parks, etc.—A city planning commission established by charter prepared (1925) a plan for the development and construction of streets, subways, bridges, playgrounds and parks. It has become a law, the first American one of such comprehensive character. In 1928 there were 95 parks (2,807.624 ac.); suburbs are often park-like in character and are of unusual beauty. Eden park (187 ac.) on Mt. Adams, about 1 m. E. of the business centre and overlooking the river, is well landscaped and has commanding views. It originally belonged to Nicholas Longworth (1782–1863), a wealthy horticulturist, who here grew the grapes from which Catawba wine, introduced by him in 1828, was made. The park contains the art museum and academy. Its gateway, Elsinore, is a mediaeval reproduction; other features are the reservoirs, which resemble natural lakes, and a high water tower, from which there is a delightful view. Public concerts are given here in a natural amphitheatre. In Burnet Woods park (116 ac.), N.W. of Eden, is the University of Cincinnati, including the library of the Historical and Philosophical society of Ohio with its great collection of Americana. There is a lake for boating and skating and public concerts are given. Recently new parks have been added and the boulevards and bluffs beautified. The Mt. Airy forestry project includes 1,132 acres. Ault park (215 ac.), Alms (62 ac.), Mt. Storm (68 ac.) and Mt. Echo park (68 ac.) afford fine views. Other large parks are Victory, Salway, Caldwell, Avon field, Kroger, Inwood, Lincoln and Garfield, and the Fleischman Rose garden. There are numerous playgrounds and athletic fields attended (summer, 1927) by some 1,000,000. The Zoological garden (60 ac.) contains unusual collections of animals in a picturesque environment. Here concerts, operas and other entertainments are given. Spring Grove cemetery (600 ac., 6 m. N.W. of Fountain square) is laid out on the park plan, as are the Catholic and Jewish cemeteries. Parkway boulevard (a part of the park system) covers the old Miami canal bed through the centre of the city and extends 4.6 miles. Victory parkway and Noyes field include some 134 acres. The Lunken airport (700 ac.) is 5 m. E. of the post office; the Watson (100 ac.) is at Blue Ash, Ohio.

Education.—There are 54 public schools, 6 junior high and 5 high schools (enrolment 69,753). About 26,000 are in the parochial schools. Students may pass at public expense from the kindergarten through the graduate departments of the municipal university of Cincinnati (1873). This university, since 1895 on a campus of nearly 50 ac., has an astronomical observatory on the highest point of Mt. Lookout and was the first strictly municipal university in the United States. It embraces a graduate school and schools of liberal arts, engineering and commerce, education, medicine, nursing and health, law, applied arts and household administration. The co-operative system, originated in Cincinnati, of supplementing college instruction by practical training in shops and manufacturing establishments is expanding greatly. The students registered 1927–28 were 8,604 and the officers of Government and instruction in excess of 700. The law department developed from the Cincinnati Law school, the oldest west of the Alleghenies and the third in the United States, a survivor of the Lancaster seminary (1814) and Cincinnati college (1819). The Medical school developed from the Medical college of Ohio (1820), the oldest west of the mountains. The Observatory dates from 1842. In 1868 the director, Cleveland Abbe, inaugurated a system of daily weather reports from which developed the U.S. Weather Bureau. Among the numerous uni-

versity buildings are a men's dormitory, the Tanner's Council Research building and a stadium. The university is governed by trustees appointed by the mayor. Its large endowments are supplemented by taxation.

The Roman Catholic St. Francis Xavier college moved its college department in 1919–1920 to a 41 ac. tract near the boulevards. Founded (1831) by Bishop Kenwick as the Athenaeum it gives the usual university instruction and degrees, completing the educational system of an arch-diocese of 12,043 sq.m. and Roman Catholic population of 220,000. It has 919 students. Other Catholic educational institutions are Mt. Saint Mary's of the West (Norwood) and St. Gregory Preparatory seminary with a station at Mt. Washington, Cincinnati.

Lane Theological seminary was founded (1829) for training Presbyterian Ministers. In 1834 it was the scene of a bitter contest between faculty and student abolitionists and the trustees, who forbade the discussion of slavery and so caused about four-fifths of the students to leave. The Ohio Mechanics institute (1828) prepares skilled workmen and industrial executives. Instruction is given in every phase of mechanics and science as well as language, history, economics and music. It maintains summer schools and day and night sessions. The Hebrew Union college (1875) is the leading American institution for preparing rabbis. It is a graduate school with a handsome building near the university. Other educational institutions of importance are the Eclectic Medical college (1845); the College of Pharmacy, dental and several business colleges.

The municipal library (700,000 vols.) serves 117,000 from its main building, 29 branches and about 200 other agencies. There are some 14 other libraries including law, medicine, science, theology, botany and pharmacy. The Law library is very complete. The Lloyd library and museum of botany and pharmacy are also important. The library of the Historical and Philosophical society of Ohio (1831) contains a valuable collection of rare books, pamphlets, maps and manuscripts. The Cincinnati Society of Natural History (1870) has a large library and a museum with a valuable palaeontological collection, particularly remains from the prehistoric cemeteries of Ohio. There is an American house for training aliens for citizenship and social service. The educational department of the Young Men's Christian association includes commercial and law schools. There is also a Young Men's Mercantile library (100,000 vols.).

Hospitals, etc.—The General hospital (1915, 850 beds, 24 buildings, 27 ac.) is perhaps the best American example of the pavilion type. It has administrative relationship with the University of Cincinnati whose Medical School adjoins it. Nearby are the Children's (1926) and the Jewish (1922) hospitals. Others are the Bethesda, Deaconess', Good Samaritan, Christ's, Christian Holmes and Seton and the Tuberculosis sanatorium. There are numerous charitable institutions. A Community chest has operated successfully for a number of years. Its budget for 1928–29 asked for \$2,014,990 and was oversubscribed about \$12,000 or \$13,000.

Water Supply.—The Water works (municipally owned; cost \$11,000,000) was virtually completed in 1907. Water is taken from the Ohio river on the Kentucky side several miles above the discharge of the city sewers. It comes through a gravity tunnel under the river to the Ohio side, the water being thence elevated by four pumping engines, each with a daily capacity of 30,000,000 gal., to settling basins; it goes through filters of the American or mechanical type, and flows thence by a gravity tunnel about 4 m. to the main pumping station, on the river bank within the city. Owing to diversified topography there are three pumping districts. In the business district Eden park reservoir stores 96 million gal. (3 average days' supply); in the Eastern hills, the Mt. Auburn and Eastern hills tanks and reservoirs contain 41 millions (2 days' supply) and in the Western hills two groups of tanks contain 9½ million gal. (2 days' supply). The treatment removes 99.94% of undesirable bacteria and various other organisms and is a combination of the European (slow sand filtration) and American (chemical) plans. The system is self-supporting.

Railways, Streets, Sewers.—Cincinnati has 627 m. of paved streets and 625 m. of sewers. There is a Rapid transit loop (initial cost, \$6,100,000) encircling the city in connection with subway, surface and elevated railways giving access to suburban and inter-urban traffic. The electric street railways and some autobus lines are owned by the Cincinnati Street Railway company which operates them on a service at cost system. There are several privately owned autobus lines.

Nine railroads operating 19 trunk lines radiate from Cincinnati using five railway depots. There are four passenger and freight lines on the river. The city owns the railway (336 m.) from Cincinnati to Chattanooga, valued at approximately \$48,000,000. It is leased to the Cincinnati, New Orleans and Texas Pacific railway company for a term ending in 2026 at a rental beginning at \$1,250,000 per year plus certain percentages of net profits.

Administration.—The Home rule charter (1917) was amended (1924) to establish the city manager form of Government with a council of nine nominated by petition and elected at large for a term of two years by proportional representation voting. The charter operated from Jan., 1926. Council elects one of its members presiding officer; he becomes mayor. Council also elects from its number a vice mayor. The city manager is chosen by council for an indefinite term at \$25,000 per year.

The bonded debt Dec. 31, 1927 was \$99,494,912.09; the net amount not self supporting was \$40,212,411.59. The excess of the rentals of the Southern Railway over the debt charges on account of the railway debt is such as to reduce this net amount to \$32,814,411.59. The tax rate in 1928 was \$24.60 per thousand, of which \$9.81 was for the city and the remainder for State, county and educational purposes. In 1927 \$45,000,000 was set aside for a 5-year programme of city, county and educational purposes.

Industries.—As listed by the U.S. Census (1920) 103 major types of industry are represented in Cincinnati as well as many smaller ones. Chamber of Commerce estimates for 1925 were: soap \$100,000,000; metal products \$68,000,000; clothing \$48,677,000; slaughtering and meat-packing \$40,372,000; printing and publishing \$34,220,000; motor vehicles \$24,790,000; bread and bakery products \$16,547,000; boots and shoes \$14,256,000; paints and varnish \$11,116,000. Cincinnati is the centre of the American radio industry. The total value of products within the city limits for 1925 was \$460,823,827; for the metropolitan district, \$700,000,000. Before the Civil War Cincinnati was the centre of the American pork-packing industry and ranked high in the production of whiskies and malt liquours. There are six national banks and 17 State banks and trust companies (capital \$26,125,000, total resources \$448,962,024). There are 234 building associations with assets of \$108,999,758. The post office receipts for 1927 were \$7,554,804.

Art, Music.—Musical development began in 1810-20; by 1825 musical academies, choral societies performing the works of Handel and Haydn, and musical publications were quite numerous. The drama was popular. It was, however, the large influx of Germans in the '40s and later that promoted music most. A *Sängerfest* was held in 1849 and again in 1870, when a hall was built for it. Under Theodore Thomas (1835-1905) the Cincinnati Musical Festival association was incorporated, and its biennial May festivals began in 1873. In 1875-78 was built the Springer music-hall and the Cincinnati college of music was endowed in 1878. Theodore Thomas was director in 1878-81; a statue of him by Barnhorn stands in Music hall. Until his death Thomas was director of the May festivals. The *Sängerfest* met in Cincinnati for the third time in 1879 and its jubilee was held there in 1899. Choral societies have been important in musical life, as has the Cincinnati Conservatory of music (1867) and the Cincinnati Symphony Orchestra (1893).

A number of early American artists, such as Eckstein and Hiram Powers, lived in Cincinnati, where German influence greatly promoted art. In 1877 an organization of women (as in the case of the Symphony Orchestra) brought about the building of the Art museum (1886). A school of design (1869) remained

a part of the university until 1884 when it was transferred to the museum. An Art academy was erected (1887) near the Art museum. Frank Duveneck was for some time director of the academy, and the Duveneck room in the museum contains the most complete collection of his works. The Rookwood pottery was the first (1880) in the United States to devote exclusive attention to art ware. The earlier wares were yellow, brown and red, then came deep greens and blues, followed by mat-glazes and by "vellum" ware (1904), a lustrous pottery resembling old parchment, with decoration painted or modelled or both. There are several art reproducing establishments.

In the centre of the city is the Tyler Davidson bronze fountain (1871) on Fountain Square. It was designed by August von Kreling and comprises 15 bronze figures cast at the royal bronze foundry in Munich; the chief is a female figure with outstretched arms (43 ft. high) from whose fingers the water falls in a fine spray. The base is of porphyry. Other notable monuments are those to Garfield by Charles H. Niehaus, to W. H. Harrison by L. T. Rebisso, George Grey Barnard's Lincoln, the Galbraith memorial, the Ft. Washington monument, McCook and Hecker busts and a monument to Ohio volunteers killed in the Civil War. The chief clubs are the Queen City (1874); Cincinnati; University; Cuvier Press; Woman's; Woman's City; Camargo; Cincinnati Country; Losantiville; Maketewah; Hyde Park; Western Hills and Riding. The Cincinnati Literary club, the oldest of the kind in the United States, dates from 1849. The Cincinnati Chamber of Commerce dates from 1839.

Several hundred religious and fraternal periodicals and technical and trade journals are published. The principal daily newspapers are the *Enquirer* (1842); *Commercial-Tribune*, *Times-Star* (*Times* 1836) and *Post* (1881). The *Freie Presse* is a German daily.

History.—The site of Cincinnati was a centre of the mound builder civilization. LaSalle is said to have passed this point on LaBelle Rivière in 1669. White traders passed down the river frequently after 1750, and the valley of the Miami ("The Miami slaughter house") was the line of Indian approach upon the early Kentucky settlements via the Licking. George Rogers Clark built two small block houses here in 1780 and 1782, but they soon disappeared.

Cincinnati was one of the first settlements (1788) in the Northwest Territory. It lies on part of the land purchased for himself and others by John Cleves Symmes (1742-1814) from the U.S. Government in 1788 (the Miami purchase). The immigrants were chiefly from New Jersey and Kentucky. When the town was first laid out early in 1789 around Ft. Washington it was called Losantiville, a hybrid word signifying "the city opposite the mouth of the Licking," but early in the next year it was named as at present in honour of Gen. St. Clair, the governor of the Northwest Territory, then president of the Pennsylvania society of the Order of Cincinnati. St. Clair arrived about this time and erected Hamilton county, with Cincinnati as its seat. Indians threatened it and the Harmar (1790) and St. Clair (1791) expeditions into Indian fastnesses were unsuccessful. In 1794 Gen. Anthony Wayne won the decisive victory of Fallen Timbers at Maumee rapids from which followed the treaty of Greenville (1795) and the end of Indian warfare. The military post became a town (incorporated 1802). In 1801 the territorial legislature, which had held its sessions here from time to time, moved to Chillicothe. Cincinnati became a city in 1819. It has had many charters with more or less varying forms of government.

The opening of steam navigation on the Ohio (1816), followed by the completion of the Miami canal (1830), and of the first section of the Little Miami Railway (1843) brought rapid development of river, canal and rail traffic and the establishment of manufacturing plants. The development of agriculture and viticulture attracted many immigrants, particularly Germans, in 1845-60. In 1819 the area of the city was approximately 3 sq.m.; this had been increased by the time of the Civil War to 7 sq.m.; in 1904 it was 42.5 sq.m., and at present (1928) 72 sq. miles.

Close commercial and social relations made anti-slavery agitation a most unpleasant topic. The abolitionists were numerous

and active and the city was an important station on the "Underground railroad," with many homes open to escaping slaves as temporary resting places. Harriet Beecher Stowe lived in the city from 1832 to 1850 and gathered there much material for *Uncle Tom's Cabin*. In 1834 came the Lane seminary controversies over slavery. In 1836 James G. Birney established his anti-slavery journal, *The Philanthropist*; mobs destroyed its presses. Many episodes of this character grew out of the feeling of some that the trade with the South would be affected by such agitation. This feeling was by no means universal and Cincinnati became the rendezvous of fugitive slaves and the scene of the activities of Salmon P. Chase, Levi Coffin and others on their behalf. When war came the community sided with the North. In 1862 the city was threatened by a Confederate force under Gen. Kirby Smith and for a time was put under martial law; the Confederates did not come very near the city, however.

In 1884 occurred the largest flood of the Ohio, and in March of that year the "Cincinnati Riots." A mob, infuriated by the lax administration of law, broke into the jail to lynch some murderers found guilty of manslaughter only. The prisoners had been removed but the mob burned the court-house with its records. The militia was called out and after a few days order was restored with 45 killed and 148 wounded.

Evils growing out of the large council retained in the new self-governing charter of 1917 led to the formation of the "citizens charter committee," which waged a campaign for a more responsible Government. As a result of their activities the charter was amended in 1924 to provide for a city-manager form of Government with a small council of nine elected by proportional representation ballot. In the election of 1925, the people approved the same bond issue which they had rejected when proposed by the former administration, thereby showing their willingness to furnish funds to further the city's growth under proper administrative responsibility. The activities of the "Citizen Republicans" also did much to weaken the hold of the old Republican "machine."

CINCINNATUS, LUCIUS QUINTIUS (b. c. 519 B.C.), one of the heroes of early Rome. He worked his own small farm. A persistent opponent of the plebeians, he resisted the proposal of Terentilius Arsa to draw up a code of written laws applicable equally to patricians and plebeians. Twice he was called to the dictatorship of Rome (458 and 439). In 458 he defeated the Aequians in a single day, and after entering Rome in triumph with large spoils returned to his farm. The story of his success, related five times under five different years, possibly rests on an historical basis, but the account given in Livy is incredible.

See Livy iii. 26-29; Dion. Halic. x. 23-25; Florus i. 11. For a critical examination of the story see Schwieger, *Römische Geschichte*, bk. xxviii. 12; E. Pais, *Storia di Roma*, i. ch. 4 (1898).

CINCLIDAE: see DIPPER.

CINDERELLA, the heroine of an almost universal fairy-tale (i.e., little cinder girl). Its essential features are (1) the persecuted maiden whose youth and beauty bring upon her the jealousy of her step-mother and sisters; (2) the intervention of a fairy or other supernatural instrument on her behalf; (3) the prince who falls in love with and marries her. In the English version, a translation of Perrault's *Cendrillon*, the glass slipper which she drops on the palace stairs is due to a mistranslation of *pantoufle en vair* (a fur slipper), mistaken for *en verre*. It has been suggested that the story originated in a nature-myth, Cinderella being the dawn, oppressed by the night-clouds (cruel relatives) and finally rescued by the sun (prince).

See A. Lang, *Perrault's Popular Tales* (1888); Marian Rolfe Cox, *Cinderella; Three Hundred and Forty-five Variants* (1893).

CINEAS, a Thessalian, the chief adviser of Pyrrhus, king of Epirus. He was regarded as the most eloquent man of his age. He tried to dissuade Pyrrhus from invading Italy, and after the defeat of the Romans at Heraclea (280 B.C.) was sent to Rome

to discuss terms of peace. These terms, which are said by Appian (*De Rebus Samniticis*, 10, 11) to have included the freedom of the Greeks in Italy and the restoration to the Bruttians, Apulians and Samnites of all that had been taken from them, were rejected. Two years later Cineas was sent to renew negotiations on easier terms. The result was a cessation of hostilities, and Cineas crossed over to Sicily to prepare the ground for Pyrrhus's campaign. Nothing more is heard of him. He is said to have made an epitome of the *Tactica* of Aeneas, probably referred to by Cicero, who speaks of a Cineas as the author of a treatise *De Re Militari*.

See Plutarch, *Pyrrhus*, 11-21; Justin xviii. 2; Eutropius ii. 12; Cicero, *Ad Fam.* ix. 25.

CINEMATOGRAPHY: see MOTION PICTURES: Technology.

CINERARIA, cultivated ornamental plants originated from species of *Senecio*. There are two distinct types, the garden species of which one of the most common is the so-called Dusty Miller, *S. cineraria* and the greenhouse varieties of *S. cruentus*, commonly referred to as Cinerarias.

Greenhouse cinerarias are of two types; one a dwarf, compact growing plant with large flowers in dense clusters; the other a taller growing variety with larger, more spreading clusters of small star-shaped flowers. These are known horticulturally as stellate varieties of *Cineraria cruenta*. Both are easily grown from seed and are sold commercially as potted plants. The very free-flowering stellate varieties are now more popular than are the large-flowered types and through a careful selection and crossing of varieties many beautiful colours are available.

For a succession of blooming plants during the late winter and spring months seeds are first sown early in August and a second sowing is made about two weeks later. As soon as the seedlings can be handled conveniently they are put in 2½" pots. Later they are shifted to 3" pots as the root system develops. The final shift into 6" flowering pots is made early in January. Soil for cinerarias should be of a light, porous character and a mixture of one-half fibrous loam, one-half leaf-mould with a liberal sprinkling of sharp sand suits them admirably. They grow best in a night temperature of from 45° to 50° F with an increase of about 10° during the day. The soft succulent character of foliage and stems make cinerarias especially liable to be attacked by green fly. The plants should be frequently fumigated with nicotine preparations or sprayed with nicotine solutions.

CINGOLI (anc. CINGULUM), a town of the marches, Italy, province of Macerata, about 14m. N.W. direct, and 17m. by road from the town of Macerata. Pop., 1,654 (town); 13,734 (commune). Cingulum, a town of Picenum, founded by Caesar's lieutenant, T. Labienus, at his own expense in 63 B.C., played an important part in the civil wars owing to its lofty site (2,300ft.). Remains of the ancient city walls survive and there are interesting works of art in the Gothic church of S. Esuperanzio.

CINNA, a Roman patrician family of the gens Cornelia. The most prominent member was LUCIUS CORNELIUS CINNA, who, after serving in the war with the Marsi as praetorian legate, became consul in 87 B.C. After Sulla's departure for the East, riots broke out in Rome, and Cinna was expelled. He at once collected an army, Marius joined him, and the two captured Rome. Proscriptions followed, and the death of Marius (Jan. 86) left Cinna leader of the party. L. Valerius Flaccus became his colleague, and afterwards Cn. Papirius Carbo. In 84, however, Cinna, who was still consul, was forced to advance against Sulla; but while embarking his troops for Thessaly, he was killed in a mutiny. His daughter Cornelia was the wife of Julius Caesar, but his son, L. CORNELIUS CINNA, praetor in 44 B.C., sided with Caesar's murderers.

The hero of Corneille's tragedy *Cinna* (1640) was the Cn. Cornelius Cinna pardoned by Augustus for conspiracy.

CINNA, GAIUS HELVIUS, Roman poet of the later Ciceronian age, the friend of Catullus, whom he accompanied to Bithynia in the suite of the praetor Memmius. Suetonius, Valerius Maximus, Appian and Dio Cassius all state that, at Caesar's funeral, a certain Helvius Cinna was killed by mistake for Cornelius Cinna, the conspirator. The last three writers mentioned

above add that he was a tribune of the people, while Plutarch states that the Cinna who was killed by the mob was a poet. This points to the identity of Helvius Cinna the tribune with Helvius Cinna the poet. The chief objection to this view is based upon two lines in 9th eclogue of Virgil, supposed to have been written 41 or 40 B.C., which seem to imply that Helvius Cinna was then alive. But such an interpretation of the passage is not absolutely necessary. Cinna's chief work was a mythological epic poem called *Smyrna*. A *Propempticon Pollionis*, a send-off to [Asinius] Pollio, is also attributed to him. In both these poems, the language of which was so obscure that they required special commentaries, his model appears to have been Parthenius of Nicaea.

See A. Weichert, *Poëtarum Latinorum Vitae* (1830); L. Müller's edition of Catullus (1870), where the remains of Cinna's poems are printed; A. Kiessling, "De C. Helvio Cinna Poëta" in *Commentationes Philologicae in honorem T. Mommsen* (1878); O. Ribbeck, *Geschichte der römischen Dichtung*, i. (1887); Teuffel-Schwabe, *Hist. of Roman Lit.* (Eng. tr. 213, 2-5); Plessis, *Poésie latine* (1909).

CINNABAR, sometimes written cinnabarite, is red mercuric sulphide (HgS), or native vermillion, the common ore of mercury (Ger. *Zinnober*). The name comes from the Greek *κιννάβαρι* used by Theophrastus, and probably applied to several distinct substances. Cinnabar is generally found in a massive, granular or earthy form, of bright red colour, but it occasionally occurs in crystals, with a metallic adamantine lustre. The crystals belong to the hexagonal system, and are generally of rhombohedral habit, sometimes twinned. Cinnabar presents remarkable resemblance to quartz in its symmetry and optical characters. Like quartz it exhibits circular polarization, and A. des Cloizeaux showed that it possessed 15 times the rotatory power of quartz (see POLARIZATION OF LIGHT). Cinnabar has higher refractive power than any other known mineral, its mean index for sodium light being 3.02, while the index for diamond is only 2.42 (see REFRACTION). The hardness of cinnabar is 3, and its specific gravity 9. Cinnabar is found in all localities which yield mercury. Hepatic cinnabar is an impure variety from Idria, in which the cinnabar is mixed with bituminous and earthy matter; and metacinnabarite is a cubic form of mercuric sulphide, this compound being dimorphous.

CINNAMIC ACID, or **PHENYLACRYLIC ACID**, is present in Peru and Tolu balsams, in storax and in some gumbenzoin, combined with benzyl alcohol as an ester. Its formula is $C_6H_5 \cdot CH : CH \cdot COOH$. It can be prepared by the reduction of phenyl propiolic acid with zinc and acetic acid, by heating benzal malonic acid, by the condensation of ethyl acetate with benzaldehyde in the presence of sodium ethylate or by the so-called "Perkin reaction"; the latter being the method commonly employed. In this process benzaldehyde, acetic anhydride and anhydrous sodium acetate are heated to about 180° C.; the mixture is made alkaline with sodium carbonate, and excess of benzaldehyde removed by a current of steam. The residual liquor is acidified with hydrochloric acid, when cinnamic acid is precipitated, and recrystallized from hot water. Cinnamic acid crystallizes in needles or prisms, melting at 133° C. It exists in two stereoisomeric varieties one of which is trimorphous. On nitration it gives a mixture of ortho- and para-nitrocinnamic acids, the former of which is of historical importance, as by converting it into orthonitrophenylpropionic acid A. Baeyer was enabled to carry out a complete synthesis of indigo (q.v.).

Cinnamic acid and its esters find employment in the production of perfumes. Its sodium salt is applied in tuberculosis; its cresol and guaiacol esters and ethyl ditrome cinnamate have also been used therapeutically.

CINNAMON, the inner bark of *Cinnamomum zeylanicum*, a small evergreen tree belonging to the family Lauraceae, native to Ceylon. The leaves are large, ovate-oblong in shape, and the flowers, which are arranged in panicles, have a greenish colour and a rather disagreeable odour. Cinnamon has been known from remote antiquity, and was highly prized among ancient nations. The tree is grown at Tellicherry, in Java, the West Indies, Brazil and Egypt, but the produce of none of these places approaches in quality that grown in Ceylon. Ceylon cinnamon of fine quality is a very thin, smooth bark, with a light-yellowish brown colour, a highly fragrant odour, and a peculiarly sweet, warm and pleas-

ing aromatic taste. Its flavour is due to an aromatic oil. This is prepared by pounding the bark, macerating it in sea-water, and then quickly distilling the whole. It is golden-yellow, with the peculiar odour of cinnamon and a hot aromatic taste. Cinnamon is principally employed in cookery as a condiment and flavouring material, being largely used in the preparation of some kinds of chocolate and liqueurs. Being a much more costly spice than cassia, that comparatively harsh-flavoured substance is frequently substituted for or added to it.

CINNAMON STONE: see GARNET.

CINNAMUS (KINNAMOS), **JOHN**, Byzantine historian. He was imperial secretary to Manuel I. Comnenus (1143-1180), whom he accompanied on his campaigns in Europe and Asia Minor. He appears to have outlived Andronicus I., who died in 1185. Cinnamus was the author of a history of the period 1118-76, which thus continues the *Alexiad* of Anna Comnena, and embraces the reigns of John II. and Manuel I., down to the unsuccessful campaign of the latter against the Turks, which ended with the rout of the Byzantine army at Myrioccephalum. Cinnamus was probably an eye-witness of the events of the last ten years which he describes. The work breaks off abruptly, and there are indications that it is an abridgement. The text is in a very corrupt state. The author's hero is Manuel; he is strongly impressed with the superiority of the East to the West, and is a determined opponent of the pretensions of the papacy; but he cannot be reproached with undue bias.

Byz.* (1836), with Du Cange's valuable notes; Migne, *Patrologia Graeca*, cxxxiii.; see also H. von Kap-Herr, *Die abendländische Politik Kaiser Manuels* (1881); C. Neumann, *Griechische Geschichtsschreiber im 12. Jahrhundert* (1888); C. Krumbacher, *Geschichte der byzantinischen Litteratur* (1897).

CINO DA PISTOIA (1270-1336), Italian poet and jurist, whose full name was GUITTONCINO DE' SINIBALDI, was born in Pistoia, of a noble family. He studied law at Bologna under Dinus Muggelanus (Dino de Rossonis: d. 1303) and Franciscus Accursius, and in 1307 is understood to have been assessor of civil causes in his native city. In that year, however, Pistoia was disturbed by the Guelph and Ghibelline feud. Cino was a Ghibelline, and had to leave Pistoia. Pitecchio, a stronghold on the frontiers of Lombardy, was yet in the hands of Filippo Vergiolesi, chief of the Pistoian Ghibellines; Selvaggia, his daughter, was beloved by Cino (who was probably already the husband of Margherita degli Ungni); and Cino betook himself to Pitecchio. He was not with the Vergiolesi at the time of Selvaggia's death (1310), at the Monte della Sambuca, in the Apennines, where the Ghibellines had been compelled to shift their camp. In 1313 the emperor died, and the Ghibellines lost their last hope. Cino appears to have thrown up his party, and to have returned to Pistoia. Thereafter he devoted himself to law and letters. After filling several high judicial offices, a doctor of civil law of Bologna in his 44th year, he lectured and taught from the professor's chair at the Universities of Treviso, Siena, Florence and Perugia in succession.

Cino, the master of Bartolus, and of Joannes Andreae the celebrated canonist, was long famed as a jurist. His commentary on the statutes of Pistoia, written in two years, is said to have great merit; while that on the code (*Lectura Cino Pistoia super codice*, Pavia, 1483; Lyons, 1526) is considered by Savigny to exhibit more practical intelligence and more originality of thought than are found in any commentary on Roman law since the time of Accursius. He was the friend and correspondent of Dante's later years, and possibly of his earlier also, and was certainly, with Guido Cavalcanti and Durante da Maiano, one of those who replied to the famous sonnet *A ciascun' alma presa e gentil core* of the *Vita Nuova*. In the treatise *De Vulgari Eloquentia* Dante refers to him as one of "those who have most sweetly and subtly written poems in modern Italian." Petrarch coupled Cino and Selvaggia with Dante and Beatrice in the fourth chapter of his *Trionfi d'Amore*. As a poet Cino has moments of true passion and fine natural eloquence. Of these qualities the sonnet in memory of Selvaggia, *Io fui in sull' alto e in sul beato monte*, and the canzone to Dante, *Avengnache di omaggio più per tempo*, are interesting examples.

The text-book for English readers is D. G. Rossetti's *Early Italian Poets*, which contains a memoir of Cino da Pistoia and some admirably translated specimens of his verse. See also Ciampi, *Vita e poesie di messer Cino da Pistoia* (Pisa, 1813).

CINQ-MARS, HENRI COIFFIER RUZÉ D'EFFIAT, MARQUIS DE (1620–1642), French courtier, was the second son of Antoine Coiffier Ruzé, marquis d'Effiat, marshal of France (1581–1632), and was introduced to the court of Louis XIII. by Richelieu, who had been a friend of his father and who hoped he would counteract the influence of the queen's favourite, Mlle. de Hautefort. He became the king's accredited favourite, master of the wardrobe and master of the horse. After distinguishing himself at the siege of Arras in 1640, Cinq-Mars became restive. He had fallen in love with Louise Marie de Gonzaga, afterwards queen of Poland, who was not disposed to favour a suitor who could not satisfy her ambition. Cinq-Mars demanded a high military command, but Richelieu opposed his pretensions and the favourite talked rashly about overthrowing the minister. He was probably connected with the abortive rising of the count of Soissons in 1641; however that may be, in the following year he formed a conspiracy with the duke of Bouillon and others to overthrow Richelieu. This plot was under the nominal leadership of the king's brother, Gaston of Orleans. The plans of the conspirators were aided by the illness of Richelieu and his absence from the king, and at the siege of Narbonne Cinq-Mars almost induced Louis to agree to banish his minister. Richelieu, however, recovered; Gaston betrayed the conspirators, and Richelieu laid before the king the proofs of the treasonable negotiations of the conspirators for assistance from Spain. Cinq-Mars was brought to trial, admitted his guilt, and was executed at Lyons on Sept. 12, 1642. The conspiracy of Cinq-Mars forms the subject of a novel by Alfred de Vigny, *Cinq-Mars*.

See d'Hancour, *La Conspiration de Cinq-Mars* (1902).

CINQUE CENTO, a term used to describe that period of the Italian Renaissance between 1500 and 1600. The word is applied especially to the artistic styles prevalent at that time, and particularly to the classicism of the high Renaissance.

CINQUEFOIL, a decorative form of five lobes or cusps.

CINQUE PORTS, the name of an association of maritime towns in the south of England, exercising a jurisdiction dating from about the time of the Norman Conquest, organized, it seems on French lines, in the 13th century, and still surviving. The ports originally constituting the body were only five in number—Hastings, Romney, Hythe, Dover and Sandwich; but to these were afterwards added the "ancient towns" of Winchelsea and Rye with the same privileges, and other places, both corporate and non-corporate, which, with the title of limb or member, held a subordinate position. To Hastings were attached the corporate members of Pevensey and Seaford, and the non-corporate members of Bulvarhythe, Petit Iham (Yham or Higham), Hydney, Leakesbourn, Northeye and Grenche or Grange; to Romney, Lydd, and Old Romney, Dengemarsh, Orwaldstone and Bromehill or Bromehill; to Dover, Folkestone and Faversham, and Margate, St. John's, Goresend (now Birchington), Birchington Wood (now Woodchurch), St. Peter's, Kingsdown and Ringwould; to Sandwich, Fordwich and Deal, and Walmer, Ramsgate, Reculver, Tonor (Estanor), Sarre (or Serre) and Brightlingsea (in Essex). To Rye was attached the corporate member of Tenterden, and to Hythe the non-corporate member of West Hythe. The jurisdiction thus extends from Seaford in Sussex to Birchington near Margate in Kent, and includes part of the Essex coast.

The duty of the Cinque Ports until the reign of Henry VII. was to furnish nearly all the ships and men that were needful for the king's service; and for a long time after they were required to give large assistance to the permanent fleet. In return for their services the ports enjoyed extensive privileges (see Jeake's *Charters of the Cinque Ports*, still the chief authority in print).

The highest office in connection with the Cinque Ports is that of the lord warden, who is also constable of Dover Castle; the offices have for centuries been held by the same persons, but are still distinct. He has a maritime jurisdiction as admiral of the ports. His power was formerly of great extent, but he has now

practically no important duty to exercise except that of chairman of the Dover harbour board. Walmer Castle was for long the official residence of the lord warden, and its use as such, though intermittent, is not obsolete.

Admiralty Jurisdiction.—The court of admiralty for the Cinque Ports exercises a co-ordinate but not exclusive admiralty jurisdiction over persons and things found within the territory of the Cinque Ports. The limits of its jurisdiction were declared at an inquisition taken at the court of admiralty, held by the seaside at Dover in 1682, to extend from Shore Beacon in Essex to Redcliff, near Seaford, in Sussex; and with regard to salvage, they comprise all the sea between Seaford in Sussex to a point five miles off Cape Grisnez on the coast of France, and the coast of Essex. An older inquisition of 1526 is given by R. G. Marsden in his *Select Pleas of the Court of Admiralty*, II. xxx. The judge sits as the official and commissary of the lord warden, just as the judge of the high court of admiralty sat as the official and commissary of the lord high admiral. And, as the office of lord warden is more ancient than the office of lord high admiral (*The Lord Warden v. King in his office of Admiralty*, 1831, 2 Hagg. Adm. Rep. 438), it is probable that the Cinque Ports court is the more ancient of the two.

The jurisdiction of the court is in theory concurrent with that of the king's court of admiralty, subject to some statutory modifications. Cases of collision have been tried in it (the "*Vivid*," 1 Asp. Maritime Law Cases, 601), but of late mainly salvage cases (the "*Clarisse*," *Swabey*, 129; the "*Marie*," *Law. Rep.* 7 P.D. 203).

Dr. (afterwards the Right Hon. Robert Joseph) Phillimore succeeded his father as judge of the court from 1855 to 1875. He was succeeded by Arthur Cohen, K.C. In 1914 Cohen resigned, and Sir F. Pollock was appointed by Lord Beauchamp, who had lately become lord warden. As Sir R. Phillimore was also the last judge of the high court of admiralty, from 1867 (the date of his appointment to the high court) to 1875, the two offices were, probably for the only time in history, held by the same person. Dr. Phillimore's patent had a grant of the "place or office of judge official and commissary of the court of admiralty of the Cinque Ports, and their members and appurtenances, and to be assistant to my lieutenant of Dover castle in all such affairs and business concerning the said court of admiralty wherein yourself and assistance shall be requisite and necessary." Of old the court sat sometimes at Sandwich, sometimes at other ports. But the regular place for the sitting of the court has for a long time been, and still is, the aisle of St. James's church, Dover. For convenience the judge has in recent times sat at the royal courts of justice. There has been no full sitting since Cohen's time. The office of marshal in the high court is represented in this court by a serjeant, who also bears a silver oar. There is a registrar who, according to general civilian practice, can act as the judge's deputy; he deals at Dover with the small matters which keep the jurisdiction alive. An appeal is to the king in council, advised by the judicial committee. For details of the jurisdiction see the Cinque Ports Act, 1821. At present the judge's only active duty is to officiate at the installation of a new lord warden.

The Cinque Ports from the earliest times claimed to be exempt from the jurisdiction of the admiral of England. Their early charters do not, like those of Bristol and other seaports, express this exemption in terms. It seems to have been derived from the general words of the charters which preserve their liberties and privileges.

The lord warden's claim to prize was raised in, but not finally decided by, the high court of admiralty in the "*Ooster Ems*," 1 C. Rob. 284, 1783. No trace has been found of any later attempt to assert it.

See S. Jeake, *Charters of the Cinque Ports* (1728); Klocker, *Grand Court of Shepway* (1862); M. Burrows, *Cinque Ports* (1895); *Indices of the Great White and Black Books of the Cinque Ports* (1905); Benoist-Lucy, *Les Cinq-Ports* (1911), a short but accurate study; J. H. Round, *Feudal England* (1895), p. 552 seq.; *Encyclopædia of the Laws of England* (2nd edition, 1907) iii. 70; Halsbury, *Laws of England*, i. 139; ix. 127; Sir F. Pollock, "Cinque Ports Jurisdiction,"

Low Quart. Rev. xli. 453. The archives of the Cinque Ports are naturally not in one place; the chief repositories are at New Romney, Dover and Rye.

CINTRA, town of central Portugal (modern spelling, Sintra), 17m. W.N.W. of Lisbon by the Lisbon-Caçem-Cintra railway, and 6m. N. by E. of Cape da Roca, the westernmost promontory of the European mainland. Pop. (1911), 7,091. Cintra is magnificently situated on the northern slope of the Serra da Cintra, a rugged mountain mass, largely overgrown with pines, eucalyptus, cork and other forest trees, above which the principal summits rise in a succession of bare and jagged grey peaks; the highest being Cruz Alta (1,772ft.). Every educated Portuguese is familiar with the verses in which the beauty of Cintra is celebrated by Byron in *Childe Harold* (1812), and by Camoens in the national epic *Os Lusíadas* (1572). One of the highest points of the Serra is surmounted by the Palácio da Pena, a fantastic imitation of a mediaeval fortress, built on the site of a Hieronymite convent by the prince consort Ferdinand of Saxe-Coburg (d. 1885); while an adjacent part of the range is occupied by the Castelo des Mouros, an extensive Moorish fortification containing a small ruined mosque and a very curious set of ancient cisterns.

In the town itself the most conspicuous building is a 14th-15th-century royal palace, partly Moorish, partly debased Gothic in style, and remarkable for the two immense conical chimneys. The 18th-century Palácio de Seteais is said to derive its name ("Seven Ahs") from a sevenfold echo; here, on Aug. 22, 1808, was signed the convention of Cintra, by which the British and Portuguese allowed the French army to evacuate the kingdom. Beside the road which leads for 3½m. W. to the village of Colares, celebrated for its wine, is the Penha Verde, an interesting country house and chapel, founded by Dom João de Castro (1500-1548), fourth viceroy of India. Castro also founded the Capuchin convent of Santa Cruz, better known as the Cork convent. Beyond the Penha Verde, on the Colares road, are the palace and park of Montserrat. The palace was originally built by William Beckford, the novelist and traveller (1761-1844), and was purchased in 1856 by Sir Francis Cook, an Englishman, who afterwards obtained the Portuguese title viscount of Montserrat. The park, with its tropical luxuriance of vegetation and its variety of lake, forest and mountain scenery, is by far the finest example of landscape gardening in the Iberian Peninsula, and probably among the finest in the world.

CIPHER or **CYPHER**, the symbol o, nought, or zero (Arab. *ṣifr*, void), and so a name for symbolic or secret writing (see **CRYPTOGRAPHY**), or for shorthand (*q.v.*), and also in elementary education for doing simple sums ("ciphering").

CIPPUS (Lat. for a "post" or "stake"), in architecture, a low pedestal, either round or rectangular, set up by the Romans for various purposes such as military or mile stones, boundary posts, etc. The inscriptions on some in the British Museum show that they were occasionally funeral memorials.

CIPRIANI, GIOVANNI BATTISTA (1727-1785), Italian painter and engraver, Pistoiese by descent, was born in Florence in 1727. He studied first under Ignatius Heckford or Hugford, and afterwards under Antonio Domenico Gabbiani. He was in Rome from 1750 to 1753, where he became acquainted with Sir William Chambers, the architect, and Joseph Wilton, the sculptor, whom he accompanied to England in Aug. 1755. When Chambers designed the Albany in London for Lord Holland, Cipriani painted a ceiling for him. He also painted part of a ceiling in Buckingham Palace, and a room with poetical subjects at Standlynch in Wiltshire. Some of his best and most permanent work was, however, done at Somerset House, London, built by his friend Chambers. He not only prepared the decorations for the interior of the north block, but, says Joseph Barretti in his *Guide through the Royal Academy* (1780), "the whole of the carvings in the various fronts of Somerset place—excepting Bacon's bronze figures—were carved from finished drawings made by Cipriani." These designs include the five masks forming the keystones to the arches on the courtyard side of the vestibule, and the two above the doors leading into the wings of the north

block, all of which are believed to have been carved by Nollekens. The grotesque groups flanking the main doorways on three sides of the quadrangle and the central doorway on the terrace appear also to have been designed by Cipriani. The central panel of the library ceiling was painted by Sir Joshua Reynolds, but the four compartments in the coves, representing Allegory, Fable, Nature and History, were Cipriani's. These paintings still remain at Somerset House, together with the emblematic painted ceiling, also his work, of what was once the library of the Royal Society. He was an original member of the Royal Academy (1768), for which he designed the diploma so well engraved by Bartolozzi. He was much employed by the publishers, for whom he made drawings in pen and ink, sometimes coloured. His friend Bartolozzi engraved most of them. Drawings by him are in both the British Museum and Victoria and Albert Museum, London. His best autograph engravings are "The Death of Cleopatra," after Benvenuto Cellini; "The Descent of the Holy Ghost," after Gabbiani; and portraits for Hollis's memoirs, 1780. He painted allegorical designs for George III.'s state coach—which is still in use—in 1782, and repaired Verrio's paintings at Windsor and Rubens's ceiling in the Banqueting House at Whitehall. He designed nymphs and *amorini* and medallion subjects to form the centre of Pergolesi's bands of ornament, and they were continually reproduced upon the elegant satin-wood furniture which was growing popular in his later days. Almost certainly some of the beautiful furniture designed by the Adams was actually painted by Cipriani himself. He also occasionally designed handles for drawers and doors. Cipriani died at Hammersmith in 1785 and was buried at Chelsea, where Bartolozzi erected a monument to his memory. He had married an English lady, by whom he had two sons.

CIRCAR, an Indian term applied to the component parts of a *subah*, or province, each of which is administered by a deputy-governor. In English it is principally employed in the name of the Northern Circars, used to designate a now obsolete division of the Madras presidency, which consisted of a narrow slip of territory lying along the western side of the bay of Bengal from 15° 40' to 20° 17' N. lat. These Northern Circars were five in number, Chicacole, Rajahmundry, Ellore, Kondapalli and Guntur, and their total area was about 30,000 sq. miles.

The district corresponds in the main to the modern districts of Kistna, Godavari, Vizagapatam, Ganjam and a part of Nellore. It was first invaded by the Mohammedans in 1471 and conquered by them in the following century, but they appear to have acquired only an imperfect possession of the country, as it was again wrested from the Hindu princes of Orissa about the year 1571. In 1687 the Circars were added, along with the empire of Hyderabad, to the empire of Aurangzeb. In 1759, by the conquest of Masulipatam, the dominion of the maritime provinces on both sides, from the river Gundlakamma to the Chilka lake, was transferred from the French to the British. But the latter left them under the administration of the nizam, with the exception of the town and fortress of Masulipatam, which were retained by the English East India company. In 1765 Lord Clive obtained from the Mogul emperor Shah Alam a grant of the five Circars. Hereupon the fort of Kondapalli was seized by the British, and in 1766 a treaty of alliance was signed with Nizam Ali, by which the company, in return for the grant of the Circars, undertook to maintain troops for the nizam's assistance. By a second treaty, signed in 1768, the nizam acknowledged the validity of Shah Alam's grant and resigned the Circars to the company, receiving as a mark of friendship an annuity of £50,000. Guntur, as the personal estate of the nizam's brother, was excepted during his lifetime under both treaties. He died in 1782, but it was not till 1788 that Guntur came under British administration. In 1823, the claims of the nizam over the Northern Circars were bought out by the company, and they became a British possession.

CIRCASSIA: see **CAUCASIAN AREA**, NORTH; **KARACHAEV**; **KABARDINE**; **INGUSHETIA**; **ADIGEL**.

CIRCASSIANS. The Cherkesses or Circassians differ from the other tribes of the Caucasus in origin and language. They designated themselves by the name of Adigheh, that of Cherkesses

being a term of Russian origin. The government under which they lived was a peculiar form of the feudal system. The free Circassians were divided into three distinct ranks, the princes or *pshi*, the nobles or *uork* (Tatar *usden*), and the peasants or *hokotil*. They were also divided into numerous families, tribes or clans, some of which were very powerful and carried on war against each other with great animosity. The slaves, of whom a large proportion were prisoners of war, were generally employed in the cultivation of the soil, or in the domestic service of some of the principal chiefs.

The will of the people was the supreme source of authority; and every free Circassian had a right to express his opinion in those assemblies of his tribe in which the questions of peace and war, almost the only subjects which engaged their attention, were brought under deliberation. The princes and nobles, the leaders of the people in war and their rulers in peace, were only the administrators of a power which was delegated to them. The administration of justice was regulated solely by custom and tradition, and in those tribes professing Mohammedanism by the precepts of the Koran. The most aged and respected inhabitants of the various auls or villages frequently sat in judgment, and their decisions were received without a murmur by the contending parties. The Circassian princes and nobles were professedly Mohammedans; but in their religious services many of the ceremonies of their former heathen and Christian worship were still preserved. A great part of the people had remained faithful to the worship of their ancient gods—Shible, the god of thunder, of war and of justice; Tleps, the god of fire; and Seosseres, the god of water and of winds. One of their marriage ceremonies was that the young man who had been approved by the parents, and had paid the stipulated price in money, horses, oxen, or sheep for his bride, was expected to come with his friends fully armed and to carry her off by force from her father's house. Every free Circassian had unlimited right over the lives of his wife and children. Although polygamy was allowed by the laws of the Koran, the custom of the country forbade it. The respect for superior age was carried to such an extent that the young brother used to rise from his seat when the elder entered an apartment, and was silent when he spoke. Circassians were distinguished for the most generous hospitality and implacable vindictiveness. The individual who had slain any member of a family was pursued with implacable vengeance by the relatives, until his crime was expiated by death. The murderer might, indeed, secure his safety by the payment of a certain sum of money, or by carrying off from the house of his enemy a newly-born child, bringing it up as his own and restoring it when its education was finished. In either case, the family of the slain individual might discontinue the pursuit of vengeance without any stain upon its honour. The man closely followed by his enemy, who, on reaching the dwelling of a woman, had merely touched her hand, was safe from all further pursuit so long as he remained under the protection of her roof. The commission of theft was not considered so disgraceful as its discovery. The Circassian father was always willing to part with his daughters to Turkish merchants for the harems of eastern monarchs. But no degradation was implied in this transaction, and the young women themselves were generally willing partners in it. Herds of cattle and sheep constituted the chief riches of the inhabitants. The princes and nobles, from whom the members of the various tribes held the land which they cultivated, were the proprietors of the soil. The Circassians carried on little or no commerce.

CIRCE, in Greek legend, a famous sorceress, the daughter of Eolus and the ocean nymph Perse. She was able by means of spells and incantations to change human beings into the forms of wolves or lions, and with these beings her palace was surrounded. Ulysses visited her island, Aiaie, with his companions, whom she changed into swine, but the hero, protected by the herb *moly*, which he had received from Hermes, compelled her to restore them to their original shape. He lived with her for a year, and when he determined to leave, she instructed him how to sail to the House of Hades in order to learn his fate from the prophet Tiresias. Upon his return she also gave him directions for avoid-

ing the dangers of the journey home (Homer, *Odyssey*, x.-xii.; Hyginus, *Fab.* 125). Graeco-Italian tradition placed her island near Italy, or located her on the promontory Circei. Cf. Pictus, SCYLLA.

See C. Seeliger in W. H. Roscher's *Lexikon der Mythologie*.

CIRCEIUS MONS (mod. MONTE CIRCEO), an isolated promontory on the south-west coast of Italy, about 80m. S.E. of Rome. It is a ridge of limestone about $3\frac{1}{2}$ m. long by 1m. wide at the base, running from east to west and surrounded by the sea on all sides except the north. The land to the north of it is 53ft. above sea-level, while the summit of the promontory is 1,775ft. The origin of the name is uncertain: it has naturally been connected with the legend of Circe. It is true that the promontory ceased to be an island at a very early date; but it looks exactly like one from a distance. Upon the east end of the ridge are the remains of an *enceinte*, forming a rectangle of about 200 by 100yds. of very fine polygonal work. It seems to have been an acropolis, and contains no traces of buildings, except for a subterranean cistern, circular, with a beehive roof of converging blocks. The modern village of S. Felice Circeo occupies the site of the ancient town, the citadel of which stood on the mountain top, for its mediaeval walls rest upon ancient walls of Cyclopean work of less careful construction than those of the citadel, and enclosing an area of 200 by 150yds.

Circeii was founded as a Roman colony at an early date. At the end of the republic, the city of Circeii was no longer at the east end of the promontory, but at the south end of the Lago di Paola (a lagoon—now a considerable fishery—separated from the sea by a line of sandhills and connected with it by a channel of Roman date; Strabo speaks of it as a small harbour). The transference of the city did not, however, mean the abandonment of the east end of the promontory, on which stand the remains of several very large villas. An inscription, indeed, cut in the rock near S. Felice, speaks of this part of the *promontorium Veneris* (the only case of the use of this name) as belonging to the city of Circeii. For its villas Cicero compares it with Antium, and both Tiberius and Domitian possessed residences there. The villa of the latter indeed, on the east shores of the Lago di Paola, has been mistaken for the Roman town of Circeii. It extends over an area of some 600 by 500yds., consisting of fine buildings along the lagoon, including a large open *piscina* or basin, surrounded by a double portico, while farther inland are several very large and well-preserved water-reservoirs, supplied by an aqueduct of which traces may still be seen. The beetroot and oysters of Circeii had a certain reputation.

The view from the highest summit of the promontory (which is occupied by ruins of a platform attributed with great probability to a temple of Venus or Circe) is of remarkable beauty; the whole mountain is covered with fragrant shrubs. From any point in the Pomptine Marshes or on the coast-line of Latium the Circeian promontory dominates the landscape in the most remarkable way.

See G. Lugli, *Forma Italiae* 1. i. 2. (1928), the Italian archaeological survey.

CIRCLE, a curve consisting of all those points of a plane which lie at a fixed distance from a particular point in the plane, called the *centre*.

The circle is the simplest and most useful *plane curve* and alone possesses the property of being exactly alike at all points. If the curve be turned in its plane about its centre, the new position taken up is the same as the original position. This property constitutes the "roundness" of the circle, and distinguishes it from other plane curves. A circle may be traced upon a plane by the continuous movement of a point rigidly connected with the centre, as in the use of compasses, and it is in part the simplicity of this construction which explains the fundamental importance of this curve. The tracing of a circle is a much simpler problem than the tracing of a straight line, since the common method of drawing the latter, with the aid of a ruler, only reproduces the straight line already constructed along the ruler's edge. A difference in the use of the word "circle" is observable between the older writers and those of the present century. With the former

the word is understood to mean the part of the plane enclosed by the curve, while the curve itself is called the *circumference*. The latter consider the circle and its circumference identical, except that the latter is often spoken of as the measure of the former; and the enclosed portion of the plane is spoken of as the *interior*, not as the circle itself.

The straight line joining the centre to a point on the circle, e.g., OP or OQ (fig. 1) is called a *radius*; from the definition of a circle, the radii drawn to various points on the circle are equal.

A straight line drawn through the centre and having its ends on the circle, e.g., EOH (fig. 1) is called a *diameter*; evidently all diameters of the same circle are equal in length, and twice as long as a radius. A straight line, such as ABC (fig. 1), joining any two points on a circle is called a chord; and the greatest possible chord is a diameter. The portion of the circle intercepted between two points is called an *arc*. Any two points on the circle divide it into two arcs; thus, in fig. 1, ADC is the *minor arc*, and $APEC$ the *major arc*, between A and C .

The figure composed of an arc and the chord joining its extremities is a *segment* of the circle. In fig. 1, $ADCB$ and $APECB$ are respectively the minor and major segments made by the chord AC . A *sector* of a circle is the figure formed by two radii and one of the arcs joining their extremities. The angle between these radii and within the sector is called the angle of the sector. Thus $ODKC$ (fig. 1) is a sector, and DOC its angle.

Geometrical Properties.—A number of properties of the circle are direct results of the symmetry and regularity of the curve. For instance, if two chords in the same circle are equal, the arcs corresponding to them are equal; if two sectors of the same circle have equal angles, they have equal arcs, and contain equal areas, etc. A useful property of this kind is that *every chord is bisected by the perpendicular drawn to it from the centre*. This allows the centre to be found when the circle is given, and to draw the circle when three points on it are given. Thus, to construct the circle through H , P and Q , draw the perpendicular bisectors LO and RO to HP and PQ as in fig. 1, and take as centre the point O where these meet.

A less evident property is that, *when any arc is taken, the angle between the lines joining its end-points to the centre is double the angle between the lines joining these end-points to any point on the remaining part of the circle, each angle being measured in the position facing the arc*. In fig. 1, by using the minor arc CD , the angle COD is double the angle CED , and also double the angle CAD . By using the major arc APE , the outer (reflex) angle AOE is double either ACE or ADE . An immediate consequence is that the angle ACE is equal to the angle ADE . Here A , C , D and E are any four points on a circle so placed that C and D lie on the same arc having A and E for end-points. The theorem is commonly stated in the form: *angles in the same segment are equal*. (To exhibit the segment it is necessary to join AE .) It is a property of wide application, and numerous instances of it may be seen in fig. 1 by joining various pairs of points. Thus the angles CAD , CED , CGD , CQD (when the lines CQ , QD and CG are drawn), are equal. In particular, *the angle in a semi-circle is a right angle*. Closely related to this is the theorem that *a four-sided figure whose four corners all lie on the same circle has the sum of either pair of opposite angles equal to two right angles*. The converse is true that if the sum of one of the pairs of opposite angles of a four-sided plane figure is two right angles, a circle may be drawn to pass through the four corners.

It is readily seen that a straight line whose shortest distance from the centre is less than the radius cuts a circle in two points,

FIG. 1.—THE CIRCLE AND ITS PARTS Showing the radius OP or OQ , diameter EOH , chord ABC , minor arc ADC , major arc $APEC$, minor and major segments $ADCB$ and $APECB$, sector $ODKC$ and the angle of sector DOC

and that a line whose shortest distance is greater than the radius does not meet the circle at any point. The intermediate case occurs when the line is at a distance from the centre equal to the radius, as is the case with SPT (fig. 1). Such a line has only one point in common with the circle; it is said to *touch* the circle and is called a *tangent* to the circle. The tangent at any point of a circle is the line through that point drawn at right angles to the radius; thus OPT is a right angle. The tangent at P is the limiting position approached by a chord PQ , drawn through P , as the other extremity Q approaches P . The chord must be prolonged as shown in the figure, in order that it may not be lost as its length vanishes. It is known that the perpendicular OR from the centre falls on the middle point of the chord. As Q moves to Q' , R moves to R' , and, as Q approaches P , R approaches P also. Finally the right angle ORQ approaches the limiting position OPT , and the chord PQ , prolonged sufficiently, is finally represented by the tangent PT at right angles to the radius OP . This second view of a tangent, as the limiting form of a short chord, is more generally applicable than the former, being valid for curves other than circles. It also enables many tangent theorems to be recognized as the limiting forms of related theorems on chords, and leads to a better understanding of tangent relations.

From a point F outside a circle two tangents may be drawn. The points of contact G and G' of these may be found by first drawing the tangent at a point P on the circle, finding with the compasses a point S on this such that $OS=OF$, and then finding G and G' on the circle and at distance from F equal to PS . The angle made by a tangent with a chord through its point of contact is equal to the angle in the segment on the other side of the chord. Thus the angle FGD is equal to the angle GED . An important theorem on intersecting chords follows readily from the law of equal angles in a segment. *If two chords intersect, the product of the distances of the extremities from the point of intersection is the same for either chord*. Thus, in fig. 1, AC and DE intersect at B . The figure represents the case where AB contains 4.5 units, BC 3.2 units, DB 1 unit, and BE 14.4. It will be seen that $4.5 \times 3.2 = 1 \times 14.4$. The relation remains true when the chords have to be prolonged to meet outside the circle, as AD and CE , meeting at F . In the figure $AF=7.2$, $DF=3.2$, $CF=1.6$ and $EF=14.4$, so that $AF \times DF = CF \times EF$, each being 23.04. In the case of external intersection each of the equal products is also equal to the square of the tangent from the point of intersection. In the figure, $FG=4.8$, the square of which is 23.04. This is one of the cases where the tangent represents a chord whose ends are coincident.

Circle Constructions.—The circle plays an important part in the problems of constructive geometry. This will be easily understood when it is remembered that, in the traditional view, a geometrical solution means a solution by ruler and compasses; that is, the only steps available are to rule a straight line through two given points and to draw a circle having a given centre and radius. It is therefore a matter of importance to the student of geometry to be able to construct circles to satisfy various standard sets of conditions; and several of these processes will be indicated briefly:

1. *Circle through three given points.* The method of finding the centre by the right bisectors of the joining lines has already been given. When the three points are thought of as the corners of a triangle, the circle is said to be *circumscribed* to the triangle.

2. *Circle touching three given straight lines.* Bisect the angles between two of the lines l and m , obtaining a pair of bisector lines a and b . Bisect in the same way the angles between l and the third line n by a pair of bisectors c and d . The centre of a circle touching l and m must be equidistant from l and m , and so must lie either on a or on b . The centre of a circle touching l and n must be either on c or on d . Four solutions are obtained, the positions of the centre being the intersections of a and c , of a and d , of b and c , and of b and d . The circle that lies between the given lines and touches them is said to be *inscribed* to the triangle.

3. *Circle through two given points and touching a given line* (which does not pass between the points). Let A and B be the

given points, and l the given line (fig. 2). Let AB cut l in O . Draw any circle c through A and B , by taking as centre any point on the right bisector of AB . Draw the tangent OT touching c at T . Find points H and K on l so that $KO=OH=OT$. The circle c_1 through A, B and H and the circle c_2 through A, B and K will each be a solution of the problem. The proof is briefly that $OH^2=OK^2=OT^2=OA \cdot OB$, so that OH and OK are each of the right length for a tangent from O .

4. *Circle through a given point and touching two given lines.* Let l and m (fig. 2) be the given lines, and A the given point. Draw n , the bisector of that angle between l and m in which A lies. Draw Al perpendicular to n and prolong to B so that $LB=AL$. The circles c_1 and c_2 constructed as in 3 to pass through A and B and to touch l will then constitute the two solutions of the problem.

Circle constructions in which some of the conditions are that the circle should touch certain given circles require refined geometrical methods. A celebrated case of this type is Apollonius's problem: —to construct a circle to touch three given circles. If the three circles are entirely external to one another, this problem admits of eight solutions. A number of problems of this kind, due to Jakob Steiner and others, are discussed by Coolidge (see bibl.). It is often useful to remember that a circle through two given points may have its centre anywhere on the right bisector of their joining line, and that a circle touching two given intersecting straight lines has its centre anywhere on either of the lines bisecting the angles between them. A circle through a given point and touching a given line has its centre on a curve known as a parabola; but this fact is not of much direct assistance in finding constructions.

In many cases a point moving under specified conditions traces a circular path. The definition of the circle shows that this curve is the *locus* (or path) of a variable point whose distance from a fixed point remains constant. But there are numerous other ways in which the circular path may be recognized. If the base of a triangle is fixed, and the angle at the vertex is of constant magnitude, the moving vertex traces an arc of a circle as long as it remains on the same side of the fixed base; the property involved here is that of equal angles in a segment. If the base of a triangle is fixed, and the other two sides are in constant ratio, the moving vertex traces a circle which encloses one of the fixed vertices. If the sum of the squares of the distances of a variable point from two fixed points is constant, the point traces to a circle whose centre is half-way between the two fixed points.

Analytic Treatment.—We may take for axes of reference two lines OX and OY at right angles; and, drawing PN perpendicular to OX from any point P , denote by x and y the measurements ON and NP . The two quantities x and y are called the co-ordinates of P , and the position of P depends on their values. If C is a fixed point (h, k) , P will be restricted to a circle of centre C and radius r provided $CP=r$; i.e., $CP^2=r^2$, or $CL^2+LP^2=r^2$, if CL is perpendicular to NP ; therefore

$$(x-h)^2+(y-k)^2=r^2 \quad (1)$$

This is the *equation of the circle*. The variable point P will lie on the circle if, and only if, (1) is satisfied.

The equation $x^2+y^2+2ax+2by+c=0$ (2)

FIG. 2.—SHOWING THE CONSTRUCTION OF A CIRCLE THROUGH TWO GIVEN POINTS AND TOUCHING A GIVEN LINE, AND THROUGH A GIVEN POINT TOUCHING TWO GIVEN LINES

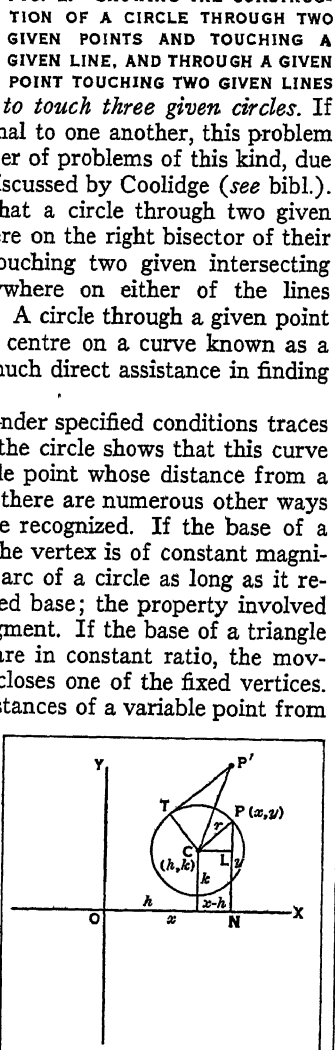

FIG. 3.—ANALYSIS OF THE CIRCLE TO DETERMINE ITS EQUATION

may be written in the form $(x+a)^2+(y+b)^2=a^2+b^2-c$, which is equivalent to (1) if $h=-a$, $k=-b$ and $r^2=a^2+b^2-c$. The last of these conditions is not possible for any real value of r if a^2+b^2-c is negative; but, if a^2+b^2-c is positive, the equation (2) is seen to represent a circle whose centre is $(-a, -b)$ and radius $\sqrt{a^2+b^2-c}$. The constants a, b and c in (2) may be determined to satisfy specified conditions, and the circle becomes then definitely fixed. For instance, if the circle is to pass through three given points, the co-ordinates of these must satisfy the equation (2), and, on substituting them for x and y , three equations are obtained giving a, b and c . If the point (x, y) is not on the circle, but outside it, as at P' (fig. 3), the left-hand side of equation (2) is not equal to zero, but, when written as $(x+a)^2+(y+b)^2-(a^2+b^2-c)$, or $(x-h)^2+(y-k)^2-r^2$, is seen to represent CP'^2-CT^2 (if $P'T$ is a tangent), which is $P'T^2$.

A point (x, y) from which the tangent to the circle (2) is equal to the tangent to the circle $x^2+y^2+2a'x+2b'y+c'=0$ (3) satisfies the equation

$$x^2+y^2+2ax+2by+c=x^2+y^2+2a'x+2b'y+c';$$

$$\text{i.e., } 2(a-a')x+2(b-b')y+(c-c')=0.$$

This equation (if the circles (2) and (3) have not the same centre) is of the first degree, so that the point (x, y) lies on a fixed straight line, called the *radical axis* of the circles. If the circles (2) and (3) have two points in common, the radical axis is the line joining these points. The equation $x^2+y^2+2kx+c=0$ represents, for different values of c , different circles of which any two have OY for radical axis. These circles are said to form a *coaxial system*. If c is negative, all the circles pass through the same two points on OY . If c is positive, none of the circles intersect. In either case one circle of the system may be found to pass through any given point not on OY .

The equation of the tangent at a point (x_1, y_1) on the circle (2) may be shown to be

$$xx_1+yy_1+a(x+x_1)+b(y+y_1)+c=0. \quad (4)$$

If, however, (x_1, y_1) is not on, but outside the circle, equation (4) represents the *polar* of (x_1, y_1) that is the straight line joining the points of contact of tangents from (x_1, y_1) .

Mensuration of the Circle.—The ratio of the length of the circumference to the diameter is the same for all circles. This number can only be calculated approximately, and is 3.141592-65358979323846 as far as 20 places of decimals. The true value of this number is always denoted by π , and has been recognized from antiquity as a most important constant. $\frac{22}{7}$ may be used as a rough approximation to π . Mathematicians have devoted an incredible amount of time to the calculation of this number, even reaching hundreds of decimal places. It is difficult to believe, however, that more than about ten figures could ever be put to any practical use; in fact 3.1415926 is likely to serve well enough. If r is the radius, the length of the whole circumference is $2\pi r$.

Let s measure the arc AB , c the chord AB , and h the distance from the middle of the arc to the chord. By dividing up the area of the sector AOB as suggested (fig. 4), and reasoning from the sum of a number of small triangles, it is inferred that the area of the sector is $\frac{1}{2}rs$; and the area of the whole circle is $\frac{1}{2}r \times 2\pi r = \pi r^2$.

It has long been known that no construction by ruler and compasses can furnish a straight line of length equal to that of the circumference of a given circle, or a square equal in area to a given circle; though in ancient times "squaring the circle" was considered an important unsolved problem. Also a straight line cannot be constructed equal to any given arc of a circle, though approximate methods exist which work well for an arc which is not

FIG. 4.—DIAGRAM SHOWING A METHOD OF DETERMINING THE AREA OF A CIRCLE

too large compared with the radius. For instance, produce AB to P , making $BP = \frac{1}{2} AB$. With centre P and radius PA draw an arc cutting at Q the tangent at B . Then $BQ =$ the arc AB approximately. For an arc forming a quarter circle the error is about one part in 300. For $\frac{1}{3}$ of the circumference the error is less than one in a million. An approximate relation between c , h and s is $s = c + 8h^2/(3c)$. For a value of h less than $\frac{1}{10}$ of c , this gives s to within $\frac{1}{10,000}$ of its value. The radius of the circle does not appear in this relation. As an example of its use, if $c = 144$, and $s = 144.2$, then $h = 3.3$.

BIBLIOGRAPHY.—Euclid, *Elements*, Bk. III; J. L. Coolidge, *A Treatise on the Circle and the Sphere* (1916); H. S. Hall and F. H. Stevens, *A School Geometry* (1924); D. M. Y. Sommerville, *Analytical Conics* (1924).

CIRCLEVILLE, a city of Ohio, U.S.A., on the Scioto river, 25m. S. of Columbus; the county seat of Pickaway county. It is on Federal highway 23, and is served by the Norfolk and Western and the Pennsylvania railways. The population in 1930 was 7,369. Canned vegetables, pork products, straw paper for boxes and sealing-wax are among its distinctive manufactures. An annual pumpkin show is held.

The city was laid out (1806) within a circular embankment of prehistoric origin, with an octagonal court-house in the centre and circular streets around it. The court-house was burned in 1841, and no trace remains of the original plan or of the ancient earth-works. The city was chartered in 1853.

CIRCUIT is a path for transmitting electrical energy.

CIRCUIT RIDER, a preacher or minister who supplies several localities, preaching at each in succession and thereby forming a "circuit." Francis Asbury, a follower of John Wesley inaugurated the custom in the United States in Nov. 1771, and for 45 years travelled on horseback, at the rate of 5,000 m. a year, preaching twice a day on weekdays and three times on Sunday. Each circuit was under the supervision of a Wesleyan conference preacher and he might have any number of lay-assistants. Any young man who showed aptness for public speaking and willingness to endure the hardships of travelling in the saddle for weeks at a time over a wild and rough country, might become an assistant and finally a circuit rider. The salary was \$64 a year until 1800, when it was raised to \$80 a year, with the horse furnished by the circuit. There were almost no meeting houses and services were held in log cabins, bar-rooms or in the open. Circuit riders were a considerable religious and moral force, especially along the frontier.

CIRCUITS, in a legal sense, are the periodical progresses of the judges of the superior courts of common law through the several counties of a given region for the purpose of administering civil and criminal justice. These modern circuits in progress have taken the place of the *eyres* or *itineria* of the ancient system. The word circuit is also applied to the rotative sittings of judges of county courts in the various towns of the districts over which they preside.

It is provided by s. 70 of the Supreme Court of Judicature (Consolidation) Act, 1925, that judges of the king's bench division of the high court and every judge of the probate division (if the state of business of that division permit) together with such commissioners of assize as may be appointed by letters patent shall be judges of assize. By virtue of their commission all judges and commissioners of assize are entitled within the districts fixed by their commission (including the counties palatine of Lancaster and Durham) to exercise all the powers of civil or criminal jurisdiction capable of being exercised by the high court, including (s. 71) the trial of revenue causes or proceedings. It is further provided by the act (s. 77) that: If at any time it appears to the lord chief justice that there is no business, or no substantial amount of business, to be transacted at the assizes about to be held at any particular place on a circuit, he may, with the concurrence of the lord chancellor, direct that assizes shall not on that occasion be held at such place.

The general regulation of circuits throughout England and Wales, in modern times, was originally provided for by s. 23 of the Judicature Act, 1875 (now replaced by s. 70 of the Supreme Court

of Judicature [Consolidation] Act, 1925). By this section power was conferred on the Crown by order in council to make regulations respecting circuits, including the discontinuance of any circuit, and the appointment of the places at which assizes are to be held on any circuit. Under this power, an order in council, dated Feb. 5, 1876, was made reconstructing and remodelling the circuit system throughout England and Wales. By virtue of this order the then existing circuits were discontinued and were replaced by fresh circuits. These, after various mutations, are now settled as follows: the northern, the north-eastern (taken from the northern), the midland, the south-eastern, the Oxford, the western, and the north Wales (with Chester) and south Wales (divisional) circuits. The delimitation of these circuits together with the names of the towns throughout England and Wales at which assizes are held are set out in some 14 orders in council, all of which are printed in *Statutory Rules and Orders*. Birmingham was first constituted a circuit town in the year 1884 and, by arrangement, the work there became the joint property of the midland and Oxford circuits. There are alternative assize towns in the following circuits, viz., on the western circuit, Salisbury and Devizes for Wiltshire and Wells and Taunton for Somerset; on the south-eastern, Ipswich and Bury St. Edmunds for Suffolk; on the north Wales circuit, Welshpool and Newtown for Montgomery; and in the south Wales (division), Cardiff and Swansea for Glamorgan.

The approximate dates for the holding of circuit assizes are: winter (about the middle of January), summer (about the middle of May), and autumn (about the middle of October). Spring assizes for both civil and criminal business are held in April and May in two circuits only, viz., at Manchester and Liverpool on the northern, and at Leeds on the north-eastern. In the past considerable difficulty was experienced in coping with assize work in the provinces and at the same time maintaining the efficiency of the common law sittings in London. With the object of obviating this as far as possible it has been arranged that certain of the common law judges shall remain in London during the whole of the circuits, and the others until their respective commission days which are generally arranged to fall on varying dates.

Counsel are not expected to practise on a circuit other than that to which they have attached themselves, unless they receive a special retainer. They are then said to "go special," and the fee in such a case is 100 guineas for a king's counsel and 50 guineas for a junior. In such cases it is customary to employ in the action one member of the circuit on which the counsel has come special. Certain rules have been drawn up by the bar council for regulating the practice as to retainers on circuit: (1) A special retainer must be given for a particular assize (a circuit retainer will not, however, make it compulsory upon counsel retained to go the circuit, but will give the right to counsel's services should he attend the assize and the case be entered for trial); (2) if the venue is changed to another place on the same circuit, a fresh retainer is not required; (3) if the action is not tried at the assize for which the retainer is given, the retainer must be renewed for every subsequent assize until the action is disposed of, unless a brief has been delivered; (4) a retainer may be given for a future assize, without a retainer for an intervening assize, unless notice of trial is given for such intervening assize. There are also various regulations enforced by the discipline of the circuit bar mess.

In Scotland the judges of the supreme criminal court, or high court of justiciary, form also three separate circuit courts, consisting of two judges each; and the country, with the exception of the Lothians, is divided into corresponding districts, called respectively the northern, western and southern circuits. On the northern circuit, courts are held at Inverness, Perth, Dundee and Aberdeen; on the western, at Glasgow, Stirling and Inveraray; and on the southern, at Dumfries, Jedburgh and Ayr. (W. W. P.)

United States.—In the Federal judiciary in the United States there are nine circuit courts of appeals. Each has appellate jurisdiction over a number of the Federal district courts, and each has from three to six judges, appointed by the President. Judges of the district courts are competent to sit on this bench. A justice of the Supreme Court formerly visited each circuit once a year but this practice has substantially been abandoned. These courts have

appellate jurisdiction over most of the matters determined by the district courts, but certain matters are taken directly to the Supreme Court. The courts of appeals, which sit at the places indicated, are composed of the following districts: First circuit at Boston, Maine, New Hampshire, Massachusetts, Rhode Island and Porto Rico; Second circuit at New York, Vermont, Connecticut, northern, southern, eastern and western New York; Third circuit at Philadelphia, New Jersey, eastern, middle and western Pennsylvania and Delaware; Fourth circuit at Richmond, Maryland, northern and southern West Virginia, eastern and western Virginia, eastern and western North Carolina and eastern and western South Carolina; Fifth circuit at Atlanta, with alternate sittings at Montgomery, Ft. Worth and New Orleans, northern, southern and middle Georgia, northern and southern Florida, northern, middle and southern Alabama, northern and southern Mississippi, eastern and western Louisiana, northern, southern, eastern and western Texas and the Canal Zone; Sixth circuit at Cincinnati, northern and southern Ohio, eastern and western Michigan, eastern and western Kentucky, and eastern, middle and western Tennessee; Seventh circuit at Chicago, Indiana, northern, southern and eastern Illinois, and eastern and western Wisconsin; Eighth circuit at St. Louis, with alternate sittings at Denver, Cheyenne and St. Paul; Minnesota, northern and southern Iowa, eastern and western Missouri, eastern and western Arkansas, Nebraska, Colorado, Kansas, North Dakota, South Dakota, eastern, western and northern Oklahoma, Wyoming, Utah and New Mexico; Ninth circuit at San Francisco, with alternate sittings at Seattle and Portland; northern and southern California, Oregon, Nevada, Montana, eastern and western Washington, Idaho, Arizona, Alaska and Hawaii.

In several of the States, such as Illinois and Massachusetts, the system of circuits prevails, with the judges sitting in succession in the various counties of the circuit. In a few States the term district judge is applied to such officials.

BIBLIOGRAPHY.—Clarence N. Callender's *American Courts, Their Organization and Procedure* (1927).

CIRCULAR NOTE, a documentary request by a bank to its foreign correspondents to pay a specified sum of money to a named person. The person in whose favour a circular note is issued is furnished with a letter (containing the signature of an official of the bank and the person named) called a letter of indication, which is usually referred to in the circular note, and must be produced on presentation of the note. Circular notes are generally issued against a payment of cash to the amount of the notes, but the notes need not necessarily be cashed, but may be returned to the banker in exchange for the amount for which they were originally issued. A forged signature on a circular note conveys no right, and as it is the duty of the payer to see that payment is made to the proper person, he cannot recover the amount of a forged note from the banker who issued the note. (See also **LETTER OF CREDIT**.)

CIRCULARS AND CIRCULARIZING, a means of advertising and selling which has reached large proportions as a result of rapid printing and postal extension in the past half century. This consists of descriptive circulars and other forms of advertising literature sent through the mails to bring about sales direct to possible customers. It has long been widely used in France and the United States, in connection with catalogues mailed on request by department stores, seedsmen and manufacturers of various articles that can be economically shipped.

With the development of the mail order houses, particularly in the United States, the use of this method of advertising has greatly extended. Catalogues of 1,000 pages or more, sometimes are sent broadcast to urban and farm dwellers alike, who give orders for clothing, pianos, agricultural implements, household utensils, and a great variety of other articles. The number of mail order houses in the United States is estimated at 125, with yearly sales approximating \$500,000,000. With the extension of the parcels post and favourable postal rates, this form of advertising has been widely adopted by manufacturers. (W. S. Hr.)

CIRCULATING MEDIUM, a term often applied to money in the broad sense of the word. It includes not only the minted coin of the realm, and the Bank of England notes, which are in effect gold certificates, but currency notes, dollar bills, cheques

and bills of exchange. All these circulate to perform the function of money as a medium of exchange. It is notable that by far the greater part of the circulating medium in modern great commercial nations now consists of paper credit instruments. In Great Britain and America the cheque is the main currency of commerce. See **MONEY**.

CIRCULUS IN PROBANDO, in logic, a phrase used to describe a form of argument in which the very fact which one seeks to demonstrate is used as a premise, *i.e.*, as part of the evidence on which the conclusion is based. This argument is one form of the fallacy known as *petitio principii*, "begging the question." It is most common in lengthy arguments, the complicated character of which enables the speaker to make his hearers forget the data from which he began. The following dialogue may serve as a simple illustration of circular argument. "He speaks with angels," said one of the Master's disciples. "How know you that?" I asked. "He himself admits it," he replied solemnly. "But suppose he lies?" I persisted. "What!" he exclaimed, "a man who speaks with angels capable of telling a lie?" (See **FALLACY**.)

CIRCUMCISION. From a medical as distinguished from a ritual aspect this simple operation consists in removal of a sufficient portion of the foreskin to allow of its free retraction beyond the glans penis. The operation is performed chiefly for purposes of cleanliness and to facilitate removal of the smegma which normally collects beneath the foreskin but sometimes is necessary to allow free passage of urine. For these purposes it is done as a preventive measure in the infant. In adults the chief reason for its performance is balanitis or inflammation beneath the foreskin due to lack of cleanliness or to the presence of a venereal sore; in this case circumcision is a necessary part of the treatment. It is noteworthy that in India the Hindus who do not circumcise ritually suffer far more frequently from cancer of the penis than the Mohammedans who circumcise. (See **MUTILATION AND DEFORMATION**.)

CIRCUMNAVIGATION OF THE WORLD. Although the efforts to find a route to the Indies had already led to the great voyages of Columbus, the Cabots, Bartholomew Diaz and Vasco da Gama, to Ferdinand Magellan was due the honour of having first sailed round the world (1519-22), although he himself died on the way. The first British circumnavigator was Sir Francis Drake (1577-80), who was followed by others, English, French and Dutch in the next two centuries, until the celebrated three voyages of Captain James Cook in 1768-70, 1772-75, 1776-79, practically completed the discovery of the main outlines of the known world. (See individual biographies and the articles **GEOGRAPHY** and **MAP**.)

CIRCUMSTANTIAL EVIDENCE is a kind of indirect evidence. Suppose something happens in the presence of witnesses who observe it, then their evidence is *direct* evidence of the occurrence. But now suppose there is no such direct evidence of the event, then we have to rely on indirect evidence, if any. Such indirect evidence usually consists of certain circumstances surrounding the event or in some way connected with it. By piecing these circumstances together we may get an intelligible, coherent account of the whole course of the event or events in question. This piecing together of the data is a kind of hypothesis, and there may be several rival hypotheses to account for the facts. But as in all cases of the use of hypotheses, the hypothesis which gives the most adequate and consistent explanation is usually accepted. Inference from circumstantial evidence resembles ordinary induction to the extent that it involves the use of hypotheses and their verification, but it is unlike ordinary induction inasmuch as it does not aim at a generalization, being concerned only with some particular event. The systematic character of inference is perhaps most obvious in the case of inference from circumstantial evidence, for it manifests most clearly the process of the imaginative construction of a coherent system out of fragmentary evidence. The most familiar occasions for the exercise of inference from circumstantial evidence are criminal cases. Criminals naturally take precautions against the possibility of direct evidence, and are usually betrayed by circumstantial evidence. See **EVIDENCE**. See A. Wolf, *Essentials of Logic* (1926).

CIRCUMVALLATION, LINES OF, in fortification, a continuous circle of entrenchments surrounding a besieged place, facing outwards, by which the besieger protected himself against the attack of a relieving army from any quarter (from Lat. *circum*, round, and *vallum*, a rampart). "Lines of contravallation" were similar works but naturally of less circumference, facing inwards, as a resistance against the sorties of the besieged.

CIRCUS, a space in the strict sense circular, but sometimes oval or even oblong, intended for the exhibition of races and athletic contests generally (Lat. *circus*, Gr. *κῑρκος* or *κῑρκος*, a ring or circle; probably "circus" and "ring" are of the same origin). The circus differs from the theatre inasmuch as the performance takes place in a central circular space, and not on a stage at one end of the building.

In Roman Antiquities the circus was a building for the exhibition of horse and chariot races and other amusements. It consisted of tiers of seats running parallel with the sides of the course, and forming a crescent round one of the ends. The other end was straight and at right angles to the course, so that the plan of the whole had nearly the form of an ellipse cut in half at its vertical axis. Along the transverse axis ran a fence (*spina*) separating the return course from the starting one. The straight end had no seats, but was occupied by the stalls (*carceres*) where the chariots and horses were held in readiness. This end constituted also the front of the building with the main entrance. At each end of the course were three conical pillars (*metae*) to mark its limits.

The oldest building of this kind in Rome was the *Circus Maximus*, in the valley between the Palatine and Aventine hills, where, before the erection of any permanent structure, races appear to have been held beside the altar of the god Consus. The first building is assigned to Tarquin the younger, but for a long time little seems to have been done to complete its accommodation, since it is not till 329 B.C. that we hear of stalls being erected for the chariots and horses. It was not in fact till under the empire that the circus became a conspicuous public resort. Caesar enlarged it to some extent, and also made a canal 10 ft. broad between the lowest tier of seats (*podium*) and the course, as a precaution for the spectators' safety when exhibitions of fighting with wild beasts, such as were afterwards confined to the amphitheatre, took place. When these exhibitions were removed and the canal (*euripus*) was no longer necessary, Nero had it filled up. Augustus is said to have placed an obelisk on the *spina* between the *metae* and to have built a new *pulvinar*, or imperial box; but if this is taken in connection with the fact that the circus had been partially destroyed by fire in 31 B.C., it may be supposed that besides this he had restored it altogether. Only the lower tiers of seats were of stone, the others being of wood, and this, from the liability to fire, may account for the frequent restorations to which the circus was subject; it would also explain the falling of the seats by which a crowd of people were killed in the time of Antoninus Pius. In the reign of Claudius, apparently after a fire, the *carceres* of stone (*tufa*) were replaced by marble, and the *metae* of wood by gilt bronze. Under Domitian, again after a fire, the circus was rebuilt, and the *carceres* increased to twelve instead of eight as before. The work was finished by Trajan. See further for seating capacity, etc., ROME: *Archaeology*, § "Places of Amusement."

The circus was the only public spectacle at which men and women were not separated. The lower seats were reserved for persons of rank; there were also various state boxes, e.g., for the giver of the games and his friends (called *cubicula* or *suggestus*). The principal object of attraction apart from the racing must have been the *spina* or low wall which ran down the middle of the course, with its obelisks, images and ornamental shrines. On it also were seven figures of dolphins and seven oval objects, one of which was taken down at every round made in a race, so that spectators might see readily how the contest proceeded. The chariot race consisted of seven rounds of the course. The chariots started abreast, but in an oblique line, so that the outer chariot might be compensated for the wider circle it had to make at the other end. Such a race was called a *missus*, and as many

as 24 of these would take place in a day. The competitors wore different colours, originally white and red (*albata* and *russata*), to which green (*prasina*) and blue (*veneta*) were added. Domitian introduced two more colours, purple and gold (*purpureus et auratus pannus*), which probably fell into disuse after his death. To provide the horses and large staff of attendants it was necessary to apply to rich capitalists and owners of studs, and from this there grew up in time four companies (*factiones*) of circus purveyors, which were identified with the four colours, and with which those who organized the races contracted for the proper supply of horses and men. The drivers (*aurigae*, *agitatores*), who were mostly slaves, were sometimes held in high repute for their skill. The horses most valued were those of Sicily, Spain and Cappadocia, and great care was taken in training them. Chariots with two horses (*bigae*) or four (*quadrigae*) were most common, but sometimes also they had three (*trigae*), and exceptionally more than four horses. Occasionally there was combined with the chariots a race of riders (*desultores*), each rider having two horses and leaping from one to the other during the race. At certain of the races the proceedings were opened by a *pompa* or procession in which images of the gods and of the imperial family deified were conveyed in cars drawn by horses, mules or elephants, attended by the colleges of priests, and led by the presiding magistrate (in some cases by the emperor himself) seated in a chariot in the dress and with the insignia of a *triumphator*. The procession passed from the capitol along the forum, and on to the circus, where it was received by the people standing and clapping their hands. The presiding magistrate gave the signal for the races by throwing a white flag (*mapa*) on to the course.

Next in importance to the Circus Maximus in Rome was the *Circus Flaminius*, erected 221 B.C. in the censorship of C. Flaminius, from whom it may have taken its name; or the name may have been derived from Prata Flaminia, where it was situated. The only games that are known to have been celebrated in this circus were the *Ludi Tourii* and *Plebei*. There is no mention of it after the 1st century. Its ruins were identified in the 16th century at S. Catarina dei Funari and the Palazzo Mattei.

A third circus in Rome was erected by Caligula in the gardens of Agrippina, and was known as the *Circus Neronis*, from the notoriety which it obtained through the Circensian pleasures of Nero. A fourth was constructed by Maxentius outside the Porta Appia near the tomb of Caecilia Metella, where its ruins are still, and now afford the only instance from which an idea of the ancient circi in Rome can be obtained. It was attributed to Caracalla, till the discovery of an inscription in 1825 showed it to be the work of Maxentius. Old topographers speak of the six circi, but two of these appear to be imaginary, the Circus Florae and the Circus Sallustii.

Circus races were held in connection with the following public festivals and generally on the last day of the festival, if it extended over more than one day:—(1) The *Consualia*, Aug. 21, Dec. 15; (2) *Equirria*, Feb. 27, March 14; (3) *Ludi Romani*, Sept. 4-19; (4) *Ludi Plebei*, Nov. 4-17; (5) *Cerialia*, April 12-19; (6) *Ludi Apollinares*, July 6-13; (7) *Ludi Megalenses*, April 4-10; (8) *Floralia*, April 28-May 3.

(2nd ed., 1885), p. 504. For existing remains see works quoted under ROME: *Archaeology*.

The Modern Circus.—The "circus" in modern times is a form of popular entertainment which has little in common with the institution of classical Rome. It is frequently nomadic in character, the place of the permanent building known to the ancients as the circus being taken by a tent, which is carried from place to place and set up temporarily on any site procurable at country fairs or in provincial towns, and in which spectacular performances are given by a troupe employed by the proprietor. The centre of the tent forms an arena arranged as a horse-ring, strewn with tan or other soft substance, where the performances take place, the seats of the spectators being arranged in ascending tiers around the central space. The traditional type of exhibition in the modern

travelling circus consists of feats of horsemanship, such as leaping through hoops from the back of a galloping horse, standing with one foot on each of two horses galloping side by side, turning somersaults from a springboard over a number of horses standing close together, or accomplishing acrobatic tricks on horseback. These performances, by male and female riders, are varied by the introduction of horses trained to perform tricks, and by drolleries on the part of the clown, whose place in the circus is as firmly established by tradition as in the pantomime.

The popularity of the circus in England may be traced to that kept by Philip Astley (d. 1814) in London at the end of the 18th century. Astley was followed by Ducrow, whose feats of horsemanship had much to do with establishing the traditions of the circus, which were perpetuated by Hengler's and Sanger's celebrated shows in a later generation. The influence of P. T. Barnum (United States), whose claim to be the possessor of "the greatest show on earth" was no exaggeration, brought about a considerable change in the character of the modern circus. In arenas too large for speech to be easily audible, the traditional comic dialogue of the clown assumed a less prominent place than formerly, while the vastly increased wealth of stage properties relegated to the background the old-fashioned equestrian feats, which were replaced by more ambitious acrobatic performances and by exhibitions of skill, strength and daring requiring the employment of immense numbers of performers and often of complicated and expensive machinery. These tendencies are, as is natural, most marked in shows given in permanent buildings in large cities, such as the London Hippodrome, which was built as a combination of the circus, the menagerie and the variety theatre, where wild animals such as lions and elephants from time to time appeared in the ring and where convulsions of nature such as floods, earthquakes and volcanic eruptions have been produced with an extraordinary wealth of realistic display. At the Hippodrome in Paris, a circus of the true classical type in which the arena is entirely surrounded by the seats of the spectators, chariot races after the Roman model were held in the latter part of the 19th century, at which prizes of considerable value were given by the management. In accordance with the developments just described, the circus may at the present time be divided into three distinct types. The British is a caravan, the continental a music-hall fitted with arena and stables, and the American a mobile arsenal of amusements. In none of these are the traditions of Philip Astley, father of the modern circus, strictly upheld. His amphitheatre, a combination of riding school and music house, retained much of the ancient dignity of horsemanship.

Since about 1920, interest in the circus has been re-awakened in several countries, including Russia, where the Soviet has permitted companies to be reorganized. In France where the vogue took long to die, as the building of the handsome Cirque de Paris a few years before the World War proves, the revival came quickly, partly because of the enthusiasm for the ring shown by the modern school of painters. This return to popularity was first marked by the redecoration of the Cirque Medrano in 1921; in the same year the Nouveau Cirque, which from 1914 had been an ordinary music-hall, was occupied by a menagerie, and, as the next step, the American bar was abolished so that the stables could be restored; the Cirque d'Hiver, the scene of Gémier's production of *Oedipe Roi*, in the season 1919-20 and afterwards a cinematograph theatre, once more became a circus in 1923-24; and this upward progression was crowned in 1923 when the French Minister of Public Instruction made the three Fratellini, the most popular clowns of France, officers of the Academy.

In Australia the Wirth Brothers have conducted a railroad circus on the American model (*see below*) for many years, but the mammoth show has yet to establish itself in Europe despite the success of Barnum and Bailey's visits between 1880-1900. In 1925, however, the Circus Krone aroused keen interest in Berlin as the only three-ring tent on the Continent, and three rings were installed in the stadium of the British Empire Exhibition, Wembley, but here the space was found in experience to be too large for the romantic smell of sawdust and tanbark to reach the audience.

International Circus.—Successful attempts to create an international circus have been made at Olympia, London. For the Christmas holidays of 1906-07 C. B. Cochran installed there a company from the Cirque de Paris with other acts; for the season of 1913-14 he brought instalments of the Hagenbeck Zoo from Berlin, thus introducing the idea of Mappin terraces into England, and engaged a German stud of 250 horses, besides an American trick rider, French clowns and many other performers, mostly from the European continent. Each Christmas since 1920 there has been at Olympia an international circus managed by Bertram W. Mills. Otherwise the British circus is still a kind of large family party travelling from town to town in little cottages on wheels and congregating each Christmas at the Agricultural Hall, Islington, just as they congregated 100 years ago in St. George's Fields.

To-day they still perform the tricks that amused the country before the circus was invented. Thus, in 1925, dogs and monkeys were acting in Bostock's Royal Italian Circus a scene called *The Deserter*, ending with the execution of a Pomeranian by a monkey seated on a pony, which recalls the drama of *The Deserter* acted by dogs and a monkey at Sadler's Wells in 1785. After most of the buildings installed by Hengler, Sanger and others, in the chief towns and cities of the United Kingdom had been put to other uses, the "tenting" companies became more like the old fair folks than Astley's performers. They exhibited personal skill instead of combining to present "equestrian dramas," of which the last relic was the Wembley stag hunt and Roman chariot races, two favourite circus items since Astley's was first built. Likewise the jester is disappearing, the fun now being provided mainly by silent clowns wearing the one-piece garment of the French "grotesque," the ill fitting evening clothes of the "Auguste" or the costume of Charlie Chaplin of the films.

Entertainments of a character similar to the circus include the International Rodeo, held under C. B. Cochran's management at the British Empire Exhibition in 1924, which was a contest in steer wrestling and buck-jumping between cowboys who were showmen in the sense that prize money was their livelihood. In July 1925 a band of Cossacks gave an exhibition of horsemanship in London and Paris, including a dramatic spectacle enlivened by comic tumbles from horseback.

UNITED STATES

The American circus is a spectacular form of entertainment, nomadic in character presenting its exhibitions in tents (rarely in buildings), and moving its performers, staff, working crew, animals and all paraphernalia on its own railway cars; or, in the case of a few small shows, by horse-drawn wagons, motor trucks or river boats. It comprises, physically, in the order met with from the approach ("front"); refreshment booths ("candy stands"); ticket and office wagons; one or more side shows ("kid shows") containing human and animal oddities; the big show main entrance ("front door"); the canopied way ("marquee") leading to the menagerie; the menagerie tent exhibiting animals caged and in corrals; the elephant "line up" and refreshment stands; the canvas-walled passage ("connection") leading from the menagerie to the main-tent ("big top"); the rear entrance ("back door") to the main-tent, opening on a compound ("back yard") in which are located performers' dressing tents, properties, property and wardrobe wagons, vehicles used in pageant ("the spec."), and other equipment essential to the production.

Early American Circus.—During colonial days several English showmen brought small troupes to the United States. Among the first was Ricketts' Circus which exhibited in the Greenwich theatre near the Battery, New York, in 1795. Probably the first American born showman of note was Rufus Welch, who in 1818 managed a wagon show and later directed larger outfits. In Nov. 1826, the Mt. Pitt Circus opened on Broome street, New York, in a building seating 3,500 persons, said at that time to be the largest

place of amusement in America. Early circuses, but subsequent to the foregoing, were those of "Old" John Robinson, Dick Sands and Van Amburgh, the two last named making European tours in the '40s.

Notable among American tent showmen may be named L. B. Lent, Adam Forepaugh, Dan Rice, the Sells brothers, W. C. Coup, P. T. Barnum, James A. Bailey and the Ringling brothers. Lent's historic New York circus played winter engagements in 14th street opposite the old Academy of Music, and toured under canvas during the summer months of the '60s and early '70s, his being the first show of size to travel by rail. Forepaugh was one of the tent world's most picturesque characters and the reputed precursor of the modern beauty contests. In 1880 he offered a prize for America's most beautiful woman, resulting in the selection of Louise Montague who thereafter rode in his street parade as "the \$10,000 beauty." Rice was the most famous of American clowns and operator of boat shows on the Mississippi. The Sells brothers, Ephraim, Allen, Lewis and Peter, in 1872 founded the show bearing their name, giving distinct impetus to the "brother idea" in the circus world. Coup, a remarkable organizer who, in 1869, projected the largest circus known up to that time, originated performances in two rings, and assisted by Dan Costello persuaded P. T. Barnum to enter the circus field. Barnum, in his 60th year, brought his internationally advertised name and ability as a proprietor of museums, impresario, lecturer and author to the tent show world, thereby giving it incalculable publicity and advancement. Bailey, generally acknowledged to have been the master showman both past and present, introduced a third ring and devised intervening stages. Brilliant alike as an organizer, originator and financial genius, he directed superb productions throughout America and toured European countries at the head of the largest circus ever sent across the Atlantic. The Ringling brothers, August G., Otto, Albert, Alfred T., Charles, Henry and John were remarkable for their individual ability to direct separate departments of their show. Beginning in 1882 the Ringlings brought the show bearing their name to a size equalling that of the largest. Upon the death of Bailey they in 1907 purchased the Barnum and Bailey "Greatest Show on Earth," but conducted it as a separate institution until 1919 when they combined it with that bearing their name.

The Modern Circus.—The consolidation is now directed by John Ringling, the only surviving brother. Contemporary circuses include Sells-Floto, Hagenbeck-Wallace, John Robinson and Sparks.

Unlike European circuses, the modern American circus sells a ticket which includes admission to both the menagerie and circus performance. Following the "big show" programme an after show is given in the main-tent for which there is an additional charge. This is called the "concert," though it has frequently taken on the character of a "wild west" entertainment. The "big show" programme appeals largely to the eye, since the greater size of the modern main-tent has rendered impossible a continuance of the "talking clown" and like audible features of the former one-ring circus. To-day the feats of human equestrians, aerialists, gymnasts, acrobats and clowns, interspersed with a number of trained jungle beasts and domestic animals are presented in ground rings, on ground platforms ("stages"), from aerial apparatus and from steel arenas so distributed as to be enclosed within or above the confines of an oval course-way ("hippodrome track") with the spectators seated in chairs ("grand stand") and on bleachers ("the blues") in such a manner as practically to surround the entire area of action.

An average of 30 different tent shows (the largest requiring approximately 100 railway cars to transport it and the smallest using but a single car) tour more or less extensively through the United States each year. The touring season usually begins in April or May and continues into November. The intervening time is spent in "winter quarters." A few small shows tour continuously, exhibiting in southern territory during the winter months. To advance their season, some circuses that are essentially tent shows open in buildings as early as March and then go out under canvas. Once on tour they exhibit only in tents. Among

these are the Ringling Bros. and Barnum and Bailey circus and the Sells-Floto show which have for many years opened in Madison Square Garden, New York, and in the Coliseum, Chicago, respectively. The indoor winter circus is practically non-existent in the United States. Creditable shows frequently play in armories and other buildings but none of these are permanent in character. (E. P. N.)

CIRENCESTER (sis'ēs-tūr or sis'ēt-ūr), market town, Gloucestershire, England, on the river Churn, 80 m. west-north-west of London. Pop. of urban district (1931) 7,200. It is served by the G.W.R.

It is the site of the Romano-British *Corinium*, at first perhaps a military post, but afterwards, a civilian city. There are ruins of an amphitheatre and indications of the walls. At Chedworth, 7 m. north-east, is a Roman villa. Cirencester (*Cirneceaster*, *Cyrenceaster*, *Cyringceaster*) is described in Domesday as ancient demesne of the crown. The manor was granted by William I. to William Fitzosbern; on reverting to the crown it was given in 1189, with the township, to the Augustinian abbey founded here in 1117 by Henry I., of which there remain a Norman gateway and a few capitals. The parish church is mainly perpendicular, with a high embattled tower. Among its many chapels that of St. Catherine has a beautiful roof of fan-tracery in stone, dated 1508. The townsmen struggled in vain throughout the middle ages to show that Cirencester was a borough. For their success against the earls of Kent and Salisbury Henry IV. in 1403 gave the townsmen a gild merchant. In 1418 the charter was annulled, and in 1477 parliament declared that Cirencester was not corporate. There are several unsuccessful attempts to re-establish the gild merchant. Besides the "new market" of Domesday Book the abbots obtained charters in 1215 and 1253 for fairs during the octaves of All Saints and St. Thomas the Martyr. The wool trade gave these great importance; in 1341 there were ten wool merchants in Cirencester, and Leland speaks of the abbots' cloth-mill, while Camden calls it the greatest market for wool in England.

Oakley Park was laid out during the 18th century by Lord Bathurst. A mile west of the town is the Royal Agricultural College originally incorporated by charter in 1845, and reorganized on new lines since 1918. There are two museums containing mosaics, inscriptions, carved and sculptured stones. The industries of Cirencester comprise various branches of agriculture. It has connection by a branch canal with the Thames and Severn canal. Cirencester became a parliamentary borough in 1572, then returning two members, but was deprived of separate representation in 1885. It is now included in the Cirencester and Tewkesbury Division of Gloucester.

CIRE PERDUE: see SCULPTURE TECHNIQUE: *Casting*.

CIRILLO, DOMENICO (1739-1799), Italian physician, botanist, and revolutionist, was appointed as a young man to a botanical professorship, and later travelled to France and England, where he was elected a fellow of the Royal Society. On his return to Naples he was appointed successively to the chairs of practical and theoretical medicine. He wrote voluminously on scientific subjects, although only his philosophical treatise *Virtù morali dell' Asine* is now remembered, and acquired a large medical practice. On the establishment of the Parthenopean republic in Naples, Cirillo became president of the legislative commission. When the town surrendered to Cardinal Ruffo, the vengeance of the royalists was wreaked upon Cirillo among many others. Despite Lady Hamilton's intercession on his behalf, Nelson had him hanged on Oct. 29, 1799.

See L. Conforti, *Napoli nel 1799* (Naples, 1889); C. Giglioli, *Naples in 1799* (1903); C. Tivaroni, *L'Italia durante il dominio francese*, vol. II.

CIRQUE, a French word used to denote a semi-circular amphitheatre, with precipitous walls, at the head of a valley in a glaciated mountain region (Lat., *circus*, ring), generally due to the basal sapping and erosion beneath the *bergschrand* of a glacier. The *bergschrand* is a large crevasse, in the form of a great symmetrical arc, parallel to the head of the *névé* (see GLACIER); it lies at a short distance from the exposed rock surface and separates the stationary from the moving ice, and in early summer,

when the glacier commences to move, it opens and exposes the rock at its base to diurnal changes of temperature. Frost action then causes rapid disintegration downwards at its base and backwards upon such part of the rock surface as is exposed in the bergschrund beneath the stationary ice, thus producing the characteristic form of the cirque.

The formation of cirques has played an important part in the development of the scenery of glaciated mountain tracts. Arêtes (sharp ridges) are formed by the intersection of two cirques, and pyramid-like peaks such as the Matterhorn and Snowdon are remnants left by the recession of three or more cirques. Cirques frequently contain lakes, for, owing to the action of the bergschrund, the floor slopes toward the mountain mass. W. D. Johnston (*Journ. of Geol.* vol. xii. p. 569) first recognized the processes giving rise to cirque formation by actually descending a bergschrund on the Mount Lyell glacier. Hollows of similar shape to cirques occur in limestone regions which may not have been glaciated. These are formed by aqueous solution and are not true cirques.

CIRRIPEDIA, a sub-class of the Crustacea (*q.v.*), comprising the barnacles and acorn shells and certain parasitic forms related to them. All Cirripedes are completely sedentary in the adult state and with the loss of the power of locomotion they have become so modified as to show, at first sight, little trace of resemblance to the more ordinary Crustacea.

The common goose-barnacle, *Lepas anatifera*, is found adhering to the bottom of ships and to floating timber. It has a fleshy stalk, fixed at one end to the supporting object and having at the other end a shell of five separate plates enclosing the body of the animal. The stalk is formed from the front part of the head, and the body, when exposed by opening the shell, is seen to be bent nearly at right angles to it. Embedded in the cement which fastens the

FIG. 1.—GOOSE OR SHIP BARNACLE (*LEPAS ANATIFERA*), SHOWING THE MUSCULAR STALKS ABOVE, AND THE FEET OR CIRRI PROTRUDING FROM THE SLIT-OPENINGS BELOW

end of the stalk to the support may be found the remains of the antennules which served for the attachment of the larva. The antennae are wanting, but within the shell the mouth is surrounded by mandibles, maxillulae and maxillae, and these are followed by six pairs of long, curled, two-branched appendages fringed with hairs. These appendages can be protruded from the slit-like opening of the shell, forming a kind of casting net for the capture of minute floating particles of food. The acorn-shells which are abundant in most seas attached to rocks in shallow water, differ from the goose-barnacle and its allies in having no peduncle. The shell is conical, cemented directly to the rock, and has an opening at the top closed by four movable valves. The shell has a more or less perfect radial symmetry. Allied to the more normal Cirripedia just described are a number of more degenerate and, for the most part, parasitic forms. The most degenerate are the members of the order Rhizocephala, of which the genus *Sacculina*, a common parasite of Crabs, is a familiar example. It has a simple sac-like body attached under the abdomen of the crab by a short stalk from which root-like processes ramify throughout the internal organs of the host. The body is enveloped by a fleshy mantle, with a small opening, and is without appendages, mouth or alimentary canal, the only organs which are well developed being those of the reproductive system. There is no trace of Arthropodous structure and only the larval development allows *Sacculina* to be referred to the Cirripedia. For the effect of *Sacculina* on its host, see Sex.

Unlike the majority of Crustacea and, indeed, of Arthropoda in general, the Cirripedia are nearly all hermaphrodite, but in a few species dwarf and degenerate male individuals are found attached at, or within, the opening of the shell of the normal individuals. The latter may be, as usual, hermaphrodites, in which case the males were termed by Darwin "complemental males"

but in a few instances the large individuals are purely female and the separation of the sexes is complete.

Most Cirripedes are hatched from the egg in the nauplius stage, but the earliest larvae are characterized by the development of spines and processes from the body and in some oceanic species these spines are of relatively enormous length. At a later stage the larva is enclosed in a bivalve shell superficially resembling that of an Ostracod and on this account it is known as the "Cypris" stage. Like the nauplius stages the cypris swims freely but ultimately it attaches itself by the antennules, which are provided with glands producing an adhesive secretion. The shell is cast off, leaving a membranous mantle within which calcareous plates appear, at first, apparently, always five in number.

FIG. 2.—WHALE BARNACLE (*CORONULA DIADEMA*), SHOWING RADIALLY SYMMETRICAL SHELL FROM ABOVE

The Cirripedia are almost exclusively marine animals, only one or two species penetrating a little way into estuaries and the like. Certain species attach themselves to whales, marine turtles, or the larger Crustacea, and truly parasitic forms are found on Echinoderms and Crustacea. The earliest fossils that can be certainly referred to the Cirripedia occur in the Rhætic formation and belong to the Lepodomorpha.

The classification of the group is still somewhat unsatisfactory. In particular, the relationship of the parasitic forms to the more normal Cirripedes is obscure. The following scheme is the most generally adopted.

Order *Thoracica*.

Order *Lepodomorpha*. The stalked barnacles. *Lepas*, *Scalpellum*, *Mitella*.

Order *Verrucomorpha*. Asymmetrical sessile forms. *Verruca*.

Order *Balanomorpha*. The symmetrical sessile acorn shells. *Balanus*, *Chthamalus*, *Coronula*.

Order *Acrothoracica*. Somewhat degenerate forms, boring in molluscan shells and corals. *Alcippe*.

Order *Ascothoracica*. Parasitic on Coelenterates and Echinoderms. Affinities obscure. *Laura*, *Dendrogaster*.

Order *Apoda*. Known only from a solitary specimen described by Darwin. Parasitic on a stalked Cirripede. *Proteolepas*.

Order *Rhizocephala*. Extremely degenerate parasites on Decapod Crustacea. *Sacculina*, *Peltogaster*.

See also BARNACLE.

(W. T. C.)

CIRTA, an ancient city of Numidia (mod. *Constantine*, *q.v.*), in Africa, in the country of the Massili. The Romans made it their road focus and strongest Numidian fortress. The early emperors neglected it, but Constantine restored it (whence mod. name). Though several Roman structures survived till recently all that remains is a part of a bridge (Pont d'Antonin) and six arches, each some 60ft. high, of an aqueduct over the Rumel valley.

See Ch. Vars, *Cirta* (Paris and Constantine, 1895).

CISCO, a city of Eastland county, Texas, U.S.A., 120m. W. by S. of Ft. Worth on Federal highway 80, and served by the Cisco and Northeastern, the Missouri-Kansas-Texas and the Texas and Pacific railways. The population was 7,422 in 1920 (over 90% native white), but fell to 6,027 in 1930 by the Federal census. It is in a gas and oil region; has several manufacturing industries; and is an important market for horses, mules, cattle, corn, wheat, cotton, peanuts, poultry and other agricultural products. Just north of the city is Williamson dam, and just below it is an immense concrete swimming-pool. Cisco was founded in May 1881, and was incorporated later in that year. It was named after John Cisco, a director of the Texas Central railway.

CISSEY, ERNEST LOUIS OCTAVE COURTOT DE (1810-1882), French general, was born at Paris on Sept. 23, 1810, and after passing through St. Cyr, entered the army in 1832. He served in Algeria and in the Crimean War, and became general of division in 1862. When the Franco-German War broke out in 1870, de Cissey was given a divisional command in the army of the Rhine, and he was included in the surrender of Bazaine's

army at Metz. He held a command in the army engaged in the suppression of the Commune. From July 1871 de Cisse sat as a deputy, and he had already become minister of war. He occupied this post several times during the critical period of the reorganization of the French army. In 1880 he was accused of treasonable relations with a German agent, but was exonerated by a court of inquiry. He died on June 15, 1882 in Paris.

CISSOID: see CURVES, SPECIAL.

CIS-SUTLEJ STATES. Southern part of the Punjab, India. Sikh chiefs south of the Sutlej passed under British protection in 1809 and the name was applied to the country south of the Sutlej and north of the Delhi territory. Before 1846 the greater part was independent, the chiefs being subject merely to control from the agent of the governor-general for the Cis-Sutlej States at Umballa. After the first Sikh War the full administration of the territory became vested in this officer. In 1849 the Punjab was annexed and the Cis-Sutlej States commissionership, comprising Umballa, Ferozepore, Ludhiana, Thanesar and Simla districts, was incorporated with the new province. The name continued to be used until 1862, when, Ferozepore having been transferred to the Lahore, and a part of Thanesar to the Delhi division, it became obsolete.

CIST, in Greek archaeology, a wicker-work receptacle used in the Eleusinian and other mysteries to carry the sacred vessels; and also, in prehistoric archaeology, a coffin formed of flat stones placed edgewise with another flat stone for a cover. Cist-burial was probably introduced into the British Isles by the Beaker-folk about 1800 B.C., but lasted in some parts down to the present era. The cist was generally, but not always covered by a round barrow or cairn.

CISTERCIANS, otherwise GREY or WHITE MONKS (from the colour of the habit, over which is worn a black scapular or apron). In 1098 St. Robert, born of a noble family in Champagne, at first a Benedictine monk, and then abbot of certain hermits settled at Molesme near Châtillon, being dissatisfied with the manner of life and observance there, migrated with twenty of the monks to a swampy place called Cîteaux in the diocese of Châlons, not far from Dijon. Count Odo of Burgundy here built them a monastery, and they began to live a life of strict observance according to the letter of St. Benedict's rule. In the following year Robert was compelled by papal authority to return to Molesme, and Alberic succeeded him as abbot of Cîteaux and held the office till his death in 1109, when the Englishman St. Stephen Harding became abbot, until 1134. In 1112, however, St. Bernard and thirty others offered themselves to the monastery, and a rapid and wonderful development at once set in. The next three years witnessed the foundation of the four great "daughter-houses of Cîteaux"—La Ferté, Pontigny, Clairvaux and Morimond. With Clairvaux Bernard's work is specially associated. At Stephen's death there were over 30 Cistercian houses; at Bernard's (1154) over 280; and by the end of the century over 500; and the Cistercian influence in the Church more than kept pace with this material expansion, so that St. Bernard saw one of his monks ascend the papal chair as Eugenius III.

The Cistercians rejected alike all mitigations and all developments of St. Benedict's rule, and tried to reproduce the life exactly as it had been in his time; indeed in various points they went beyond it in austerity. The most striking feature in the reform was the return to manual labour, and especially to field-work, which became a special characteristic of Cistercian life. In order to make time for this work they cut away the accretions to the divine office which had been steadily growing during three centuries, and in Cluny and the other Black Monk monasteries had come to exceed greatly in length the regular canonical office.

It was as agriculturists and horse and cattle breeders that, after the first blush of their success and before a century had passed, the Cistercians exercised their chief influence on the progress of civilization in the later middle ages: they were the great farmers of those days, and many of the improvements in the various farming operations were introduced and propagated by them; it is from this point of view that the importance of their extension in northern Europe is to be estimated. They depended for their income

wholly on the land. This developed an organized system for selling their farm produce, cattle and horses, and notably contributed to the commercial progress of the countries of western Europe. Thus by the middle of the 13th century the export of wool by the English Cistercians had become a feature in the commerce of the country. Farming operations on so extensive a scale could not be carried out by the monks alone, whose choir and religious duties took up a considerable portion of their time; and so from the beginning the system of lay brothers was introduced on a large scale. The lay brothers were recruited from the peasantry and were simple uneducated men, whose function consisted in carrying out the various field-works and plying all sorts of useful trades; they formed a body of men who lived alongside of the choir monks, but separate from them, not taking part in the canonical office, but having their own fixed round of prayer and religious exercises. A lay brother was never ordained, and never held any office of superiority. It was by this system of lay brothers that the Cistercians were able to play their distinctive part in the progress of European civilization. But it often happened that the number of lay brothers became excessive and out of proportion to the resources of the monasteries, there being sometimes as many as 200, or even 300, in a single abbey. On the other hand, at any rate in some countries, the system of lay brothers in course of time worked itself out; thus in England by the close of the 14th century it had shrunk to relatively small proportions, and in the 15th century the régime of the English Cistercian houses tended to approximate more and more to that of the Black Monks.

For a hundred years, till the first quarter of the 13th century, the Cistercians supplanted Cluny as the most powerful order and the chief religious influence in western Europe. But then in turn their influence began to wane, chiefly, no doubt, because of the rise of the mendicant orders, who ministered more directly to the needs and ideas of the new age. But some of the reasons of Cistercian decline were internal. In the first place, there was the permanent difficulty of maintaining in its first fervour a body embracing hundreds of monasteries and thousands of monks, spread all over Europe; and as the Cistercian very *raison d'être* consisted in its being a "reform," a return to primitive monachism, with its field-work and severe simplicity, any failures to live up to the ideal proposed worked more disastrously among Cistercians than among mere Benedictines, who were intended to live a life of self-denial, but not of great austerity. Relaxations were gradually introduced in regard to diet and to simplicity of life, and also in regard to the sources of income, rents and tolls being admitted and benefices incorporated, as was done among the Benedictines; the farming operations tended to produce a commercial spirit; wealth and splendour invaded many of the monasteries, and the choir monks abandoned field-work.

The later history of the Cistercians is largely one of attempted revivals and reforms. The general chapter for long battled bravely against the invasion of relaxations and abuses. In 1335 Benedict XII., himself a Cistercian, promulgated a series of regulations to restore the primitive spirit of the order, and in the 15th century various popes endeavoured to promote reforms. All these efforts at a reform of the great body of the order proved unavailing; but local reforms, producing various semi-independent offshoots and congregations, were successfully carried out in many parts in the course of the 15th and 16th centuries. In the 17th another great effort at a general reform was made, promoted by the pope and the king of France; the general chapter elected Richelieu (commendatory) abbot of Cîteaux, thinking he would protect them from the threatened reform. In this they were disappointed, for he threw himself wholly on the side of reform. So great, however, was the resistance, and so serious the disturbances that ensued, that the attempt to reform Cîteaux itself and the general body of the houses had again to be abandoned, and only local projects of reform could be carried out.

The Reformation, the ecclesiastical policy of Joseph II., the French Revolution, and the revolutions of the 19th century, almost wholly destroyed the Cistercians; but some survived, and since the beginning of the last half of the 19th century there has been

a considerable recovery. They are at present divided into three bodies: (1) the Common Observance, with about 30 monasteries and 800 choir monks, the large majority being in Austria-Hungary; they represent the main body of the order and follow a mitigated rule of life; they do not carry on field-work, but have large secondary schools, and are in manner of life little different from fairly observant Benedictine Black monks; of late years, however, signs are not wanting of a tendency towards a return to older ideas; (2) the Middle Observance, embracing some dozen monasteries, (3) the Strict Observance, or Trappists (*q.v.*), with nearly 60 monasteries.

Accounts of the beginnings of the Cistercians and of the primitive life and spirit will be found in the lives of St. Bernard, the best whereof is that of Abbé E. Vacandard (1895); also in the Life of St. Stephen Harding, in the *English Saints*. See also Henry Collins (one of the Oxford Movement, who became a Cistercian), *Spirit and Mission of the Cistercian Order* (1866). Useful sketches, with references to the literature, will be found in the *Catholic Encyclopaedia*, art. "Cistercians"; Herzog-Hauck, *Realencyklopädie*, "Cistercienser"; and Heimbucher, *Orden und Kongregationen* (1896), i. §§ 33, 34. On the English houses, see F. A. Gasquet's *English Monastic Life*; and on the Cistercian polity, see the same writer's "Sketch of Monastic Constitutional History," prefixed to Eng. tr. of Montalembert's *Monks of the West* (1895).

CISTUS, a genus of the family Cistaceae. The members of the family live in dry, sunny places, especially on a sandy or chalky soil. There are 20 species in the Mediterranean region; many are cultivated ornamental shrubs, in English-speaking countries commonly called rock-rose. *C. villosus* and *C. ladaniferus* yield the resin ladanum, which is not to be confused with the hypnotic laudanum.

CITADEL, a municipal fortress. The beginnings of the citadel are remote. At Tanis in Egypt there is a very ancient example; roughly quadrangular, it was built to command a stream and the adjacent ground. During the 12th dynasty of the first Theban empire a most formidable citadel was evolved, typified at Semneh, where a low wall of first defence rises upon a platform; the citadel proper is a series of crenelated buttress-redoubts projecting at short intervals from a high, rectangular wall, with an additional highly fortified projection at one corner; scaling would have been impossible without fatal casualties.

Ancient Greek citadels were usually of Cyclopean construction (see CYCLOPAEAN MASONRY) but that of Tiryns (*q.v.*) has upper walls of brick. It contains the king's palace, a fact which does not change its rôle as the true municipal fortress but which points to the origin of the municipality itself. The amalgamation of several hamlets into a *polis* or city, very frequently depended upon the existence of an *acron*, or height, which might be fortified and which became a storehouse of provisions and ammunition as well as the shrine of the god, the home of the king and the refuge of the people.

Just as the acropolis of Athens or the walled hill of the temple of Solomon in Jerusalem were vital municipal influences, so the capitol was the consolidating and protecting factor in Rome. But the citadel of Roman cities in general was less important than those of Greece. In strong countries not contiguous upon others of the same status citadels are rare because they are unnecessary. The Roman *castella* covered Europe and a part of Asia and Africa at one time; they were military centres around which a town might group itself, but they were never, in their beginnings, an integral element of normal municipal life. They existed for the empire and for themselves, and the fact that they protected municipalities was incidental.

After Rome, here and there, the citadel recovered its importance. The growth of feudalism meant the decline of the free, or nominally free, city. It should not be said, however, that in feudal times citadels ceased to be built; sometimes the right of fortification was granted by a lord and sometimes it was acquired by arms; the lord's castle might be a true citadel, or a new one might be erected by the city-State. As a type of architecture distinguished from the castle, the modern citadel is generally said to date from 1568, when the duke of Alva built one to dominate Antwerp. But the rapid multiplication of small States in the late middle ages made the citadel common in Europe.

See for architectural bibliography, CASTLE; FORTIFICATION AND SIEGECRAFT; DAREMBERG and SAGLIO, *Dict. ant. class.*, "Acropole"; PLANAT, *Enc. archit.*, "Citadelle"; C. ENLART, *Man. archéol. fr.*

CITATION, in law, a summons to appear, answering to a writ of summons at common law, and it is now in English probate practice an instrument issuing from the principal probate registry, chiefly used when a person, having the superior right to take a grant, delays or declines to do so, and another, having an inferior right, desires to obtain a grant; the party having the prior right is cited to appear and either to renounce the grant or show cause why it should not be decreed to the citator. In divorce practice, when a petitioner has filed his petition and affidavit, he extracts a citation; *i.e.*, a command drawn in the name of the sovereign and signed by one of the registrars of the court, calling upon the alleged offender to appear and make answer to the petition. In Scots law, citation is the judicial notice served upon a person convening him to court as a party litigant, a witness, a haver of documents, or a juror. Citation, as a legal term, is used in the United States to show a reference to a particular law, decision or treatise which tends to support the proposition advanced in a brief or argument. In such cases the volume, section or page, or all, is indicated.

Citation is also a military term denoting special mention for gallantry in action of a military unit, or of an individual under arms. In most nations the Citation is issued by some general officers in charge of a division or brigade, or is published by the War Department. It frequently appears in the General Orders of a military command, outlining the heroic action of those concerned. In the United States military forces the individual cited is given a silver star in recognition of his service. The *fougère* or Citation Cord is given by France to members of a unit receiving such an award. In the British and American Military forces, this *fougère* is not given but units having received it from the French or other governments are allowed to wear it. A typical General Order issued by the military command of the United States was published in General Order on July 9, 1918 (General Order 112) by the commander of the American forces, General John J. Pershing, citing the heroic action of the First and Second Divisions.

CÎTEAUX, a village of eastern France, in the department of Côte d'Or, 16 m. S.S.E. of Dijon. It is celebrated for the great abbey founded by Robert, abbot of Molesme, in 1098, which became the headquarters of the Cistercian order. The buildings which remain date chiefly from the 18th century.

CITHAERON, now called from its pine forests Elatea, a mountain range (4,626 ft.), separating Boeotia from Megaris and Attica. Its west end reaches the Corinthian Gulf; eastward it is separated from Mount Parnes by the pass through Panactum and Phyle. It was famous in Greek mythology. Here Actaeon was changed into a stag, Pentheus was torn to pieces by the Bacchantes and the infant Oedipus was exposed. It was the scene of the mystic rites of Dionysus, and the festival of the Daedala in honour of Hera. The carriage-road from Athens to Thebes traverses the picturesque pass of Dryoscephalae ("Oak-heads"), guarded on the Attic side by the ruined fortress of Ghyphthokastro ("Gipsy Castle"). Plataea is situated on the north slope, and the strategy of the battle of 479 B.C. was considerably affected by the necessity for the Greeks to keep open the passes (see PLATAEA), of Dryoscephalae, and the roads farther west from Plataea to Athens and to Megara.

CITHARA, one of the most ancient stringed instruments, may be traced back to 1700 B.C. among the Semitic races, in Egypt, Assyria, Asia Minor, Greece and the Roman empire, whence the use of it spread over Europe. Having as its leading feature a sound-box or sound-chest which consisted of two resonating tables, either flat or delicately arched, connected by ribs or sides of equal width, the cithara may be regarded as an attempt to improve upon the lyre (*q.v.*), while retaining some of its features.

The strings, varying in number from four to 20 and made of gut, hemp or silk, were vibrated by means of the fingers or of a plectrum, according to the requirements of the music and the

different quality of tone desired. Like the lyre the cithara was made in many sizes, according to the pitch required and the use to which the instrument was to be put. It was in Greece the instrument alike of the professional singer or citharoedus (*κιθαρωδός*) and, of the instrumentalist or citharista (*κιθαριστής*), and thus served the double purpose of (1) accompanying the voice (a use placed by the Greeks far above mere instrumental music) in epic recitations and rhapsodies, in odes and lyric songs; and (2) of accompanying the dance. It was also used for playing solos at the national games, at receptions and at trials of skill.

From the cithara by successive stages was evolved the guitar. The first of these steps produced the *rotta* (*q.v.*), by the construction of body, arms and transverse bar in one piece. The addition of a finger-board, stretching like a short neck from body to transverse bar, leaving on each side of the finger-board space for the hand to pass through in order to stop the strings, produced the *crwth* or *crowd* (*q.v.*), and brought about the reduction in the number of the strings to three or four. The conversion of the *rotta* into the guitar (*q.v.*) was an easy transition effected by the addition of a long neck to a body derived from the oval *rotta*. When the bow was applied the result was the guitar or troubadour fiddle. The *cittern* (*q.v.*), a later descendant of the cithara, although preserving the characteristic features of the cithara, the shallow sound-chest with ribs, adopted the pear-shaped outline of the eastern instruments of the lute tribe.

CITIES SERVICE COMPANY, incorporated on Sept. 2, 1910, in Delaware, as a holding company, controls through stock ownership more than 100 corporate enterprises in the United States, Canada, Mexico and other parts of the world, principally engaged in the production and sale of electricity, manufactured and natural gas, and petroleum. The company owns directly or indirectly the controlling interest of more than 60 public utility services in 18 States and the Dominion of Canada, serving a population of more than 4,000,000 in 900 communities including such important cities as Denver, Colo.; Toledo, O.; Kansas City, St. Joseph and Joplin, Mo.; and Kansas City and Topeka, Kan. The Public Utility companies have an installed capacity of more than 700,000 h.p. and in the year ending June 30, 1928, sold 1,340,000,000 kilowatt hours of electrical energy, 91,000,000,000 cu ft. of manufactured and natural gas. The petroleum division is a complete unit in the industry, embracing the four essential phases—production, transportation, refining and marketing. The producing properties, which are located principally in mid-continent fields (Kansas, Oklahoma and Texas), during the year ending June 30, 1928, had an average daily production of about 75,000 bbl. of crude oil.

The consolidated gross earnings of the system in the year ending June 30, 1928, were \$167,689,420; the net earnings to common stock and reserves of Cities Service company amounted to \$22,487,255, which was equivalent to 27.34% of the average amount of common stock outstanding. The capitalization as of June 30, 1928, after giving effect to the issuance of \$30,000,000 gold debentures, the application of the proceeds to the retirement or exchange of certain other funded debt, and the offering of additional common stock of the company, was as follows:

| | Outstanding |
|--|------------------|
| Common Stock (par value \$20) | 4,900,377 shares |
| \$6 Preferred Stock (no par value) | 1,034,951 " |
| 60c Preference "B" Stock (no par value) | 296,770 " |
| \$6 Preference "BB" Stock (no par value) | 63,043 " |
| 5% Gold Debentures due 1958 | \$20,591,000 " |
| 5% Gold Debentures due 1966 | 21,514,356 " |
| 5% Gold Debentures due 1963 | 30,000,000 " |
| (W. A. Jo.) | |

CITIUM (Gr. *Kition*), the principal Phoenician city in Cyprus, situated on the south-east coast at the north end of modern Larnaca (*q.v.*). Converging currents from east and west greatly facilitated ancient trade. To south and west the site is protected by salt lagoons. The earliest remains go back to an Aegean colony of Mycenaean age (c. 1400–1100 B.C.), but in historic times Citium is the centre of Phoenician influence in Cyprus. The biblical name Kittim, representing Citium, is, in fact, used quite generally for Cyprus as a whole; later also for Greeks and Romans in

general. In a list of the allies of Assur-bani-pal of Assyria in 668 B.C. a king, Damasus, of Kartihadasti (Phoenician for "New-town") occurs where Citium would be expected. A Phoenician dedication to "Baal of Lebanon," found here, suggests that Citium may have belonged to Tyre; and an official monument of Sargon II. indicates that Citium was the administrative centre of Cyprus during the Assyrian protectorate (709–668 B.C.). During the Greek revolts of 500, 386 *et seq.*, and 352 B.C., Citium led the side loyal to Persia and was besieged by an Athenian force in 449 B.C. It remained a considerable city even after the Greek cause triumphed with Alexander. But it suffered repeatedly from earthquakes and in mediaeval times its harbour became silted and the population moved to Larnaca, on the open bay. Harbour and citadel have now quite disappeared, the latter having been used to fill up the former shortly after the British occupation; some gain to health resulted, but an irreparable loss to science. There are traces of the circuit wall and many tombs.

CITIZEN: see NATIONALITY AND NATURALIZATION.

CITOLE, an obsolete musical instrument of which the exact form is uncertain. It has been supposed to be another name for the psaltery (*q.v.*).

CITRANGE, the hybrid tree and its fruit produced by crossing any variety of the sweet orange (*Citrus sinensis*) with the trifoliate orange (*Poncirus trifoliata*). At various times since 1892 American citrologists have endeavoured to produce some form of *Citrus* which would endure freezing temperatures. Several thousand seedling plants raised from cross-fertilized fruits, using both of the aforementioned species as "pollen parents," have been tested. In 1928 only five of these were citranges of cultural importance. While some citranges closely resemble oranges, all are inferior to the orange in flavour. They endure considerable frost and are used in place of lemons in various drinks and in cookery.

Citranequats, three-parent crosses made by hybridizing a kumquat with a citrange, are grown in the United States, several named varieties of these highly coloured (orange-yellow to flame-scarlet) lime-like fruits being in cultivation.

CITRIC ACID, *Acidum citricum* or HYDROXYTRICARBALLYLIC ACID, first obtained in the solid state by Karl Wilhelm Scheele, in 1784, from the juice of lemons. It is present also in oranges, citrons, currants, gooseberries and other fruits, bulbs and tubers. Citric acid, $\text{CO}_2\text{H} \cdot \text{CH}_2 \cdot \text{C}(\text{OH})(\text{CO}_2\text{H}) \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$, is made commercially on a large scale from lime or lemon juice, and also by the fermentation of glucose under the influence of *Citromyces pfefferianus*, *C. glaber* and other ferments. Lemon juice is fermented for some time to free it from mucilage, then boiled, filtered and neutralized with powdered chalk and a little milk of lime; the precipitate of calcium citrate so obtained is decomposed with dilute sulphuric acid, the solution filtered, evaporated to remove calcium sulphate and concentrated, preferably in vacuum pans. The acid is thus obtained in colourless rhombic prisms of the composition $\text{C}_6\text{H}_8\text{O}_7 \cdot \text{H}_2\text{O}$. About 20 gal. of lemon juice should yield about 10 lb. of crystallized citric acid. The acid may also be prepared from the juice of unripe gooseberries.

The synthesis of citric acid was accomplished by L. E. Grimaux and P. Adam in 1881. (See any standard textbook of organic chemistry.)

Citric acid has an agreeable sour taste. It is soluble in $\frac{1}{4}$ of its weight of cold and in half its weight of boiling water, and dissolves in alcohol, but not in ether. At 150° C it melts, and on the continued application of heat boils, giving off its water of crystallization. At 175° C it is resolved into water and aconitic acid, $\text{C}_6\text{H}_4\text{O}_6$, a substance found in *Equisetum fluviatile*, monkshood and other plants. A higher temperature decomposes this body into carbon dioxide and itaconic acid, $\text{C}_5\text{H}_4\text{O}_4$, which, again, by the expulsion of a molecule of water, yields citraconic anhydride, $\text{C}_5\text{H}_2\text{O}_3$. Citric acid digested at a temperature below 40° C with concentrated sulphuric acid gives off carbon monoxide and forms acetonedicarboxylic acid.

The citrates are a numerous class of salts, the most soluble of which are those of the alkaline metals; the citrates of the alkaline earth metals are insoluble. Citric acid, being tribasic, forms several series of salts. On warming citric acid with an excess of lime-water a precipitate of calcium citrate is obtained which is redissolved as the liquid cools.

Citric acid is used in calico printing, also in the preparation of effervescing draughts, as a refrigerant and sialogogue, and occasionally as an antiscorbutic, instead of fresh lemon juice. In the form of lime juice it has long been known as an antidote for scurvy. Several of the citrates are much employed as medicines, the most important being the scale preparations of iron. Of these iron and ammonium citrate is much used as a haematinic, and as it has hardly any tendency to cause gastric irritation or constipation it can be taken when the ordinary forms of iron are inadmissible. Iron and quinine citrate is used as a bitter stomachic and tonic. In the blood citrates are oxidized into carbonates; they therefore act as *remote alkalis*, increasing the alkalinity of the blood and thereby the general rate of chemical change within the body. (See ACETIC ACID.)

CITRON, a species of *Citrus* (*C. medica*), belonging to the tribe *Aurantieae* of the rue family (Rutaceae); the same genus furnishes also the orange, lemon, lime and shaddock or grapefruit. The citron is a small, evergreen tree or shrub growing to a height of about 10 ft.; it has irregular, straggling, spiny branches, large pale green, broadly oblong, slightly serrate leaves, with wingless petioles, and generally unisexual flowers, purplish without and white within. The large fruit is ovate or oblong, protuberant at the tip, and from 5 in. to 6 in. long, with a rough, furrowed, adhesive rind, the inner portion of which is thick, white and fleshy, the outer, thin, greenish-yellow and very fragrant. The pulp is very acid and inedible, and the seeds are bitter; the peel is very thick and when candied of very agreeable flavour. There are many varieties of the fruit, some of them of great weight and size, but only one variety, the so-called Corsican citron, is grown on an extensive commercial scale. Its large fruits are used for making candied citron, highly esteemed as a confection, of which large quantities, from 2,500,000 lb. to 4,500,000 lb. annually, are consumed in the United States. Recent researches show that the citron peel must go through a fermentation in sea water to prepare it for being candied.

The citron-tree thrives in the open air in China, Persia, the West Indies, Madeira, Sicily, Corsica, and the warmer parts of Spain and Italy; and in conservatories in more northerly regions. The rind of the citron yields a fragrant essential oil called *oil of citron* but it is seldom collected. Other varieties of *Citrus medica* yield oils known as *oil of cedro* and *oil of cedrino*.

See J. A. Risso and A. Poiteau, *Histoire naturelle des oranges* (1818-19, 2nd ed., 1872); E. Bonavia, *The Cultivated Oranges and Lemons, etc., of India and Ceylon* (1890); J. B. McNair, "Citrus Products," Parts I. and II., *Field Museum of Natural History Botanical Series*, vol. vi., nos. 1 and 2 (1926, 1927); Lucia McCulloch "Curing and Preserving Citron," *Circular no. 13, U.S. Dept. of Agric.* (1927).

CITRUS BELT, a term applied to that region of the United States where citrus fruits (oranges, lemons, grape-fruit, limes, tangerines and kumquats) can be grown successfully. The subtropical nature of these fruits limits their culture to the warmer States of the Union, including southern Georgia, Florida, the southern portions of Alabama, Mississippi, Louisiana, Texas and Arizona, and the southern three-fourths of California. In 1926 California produced 69.9% of the oranges and tangerines, 7.5% of the grape-fruit and over 99% of the lemons. In the same year, Florida produced 28.8% of the oranges and tangerines, 87.1% of the grape-fruit, 75% of the kumquats and over 99% of the limes.

CITTADELLA, a town of Venetia, Italy, province of Padua, 20m. N.W. by rail from the town of Padua; 160ft. above sea-level. Pop. (1921) 8,813 (town); 12,433 (commune). The Paduans founded Cittadella to counterbalance the Trevisan Castelfranco Veneto (founded in 1199) 8m. E.; the walls and ditch are well preserved. It is now an agricultural centre with intersection of railways: Padua-Bassano and Vicenza-Treviso.

CITTÀ DELLA PIEVE, a town and episcopal see of Umbria, Italy, in the province of Perugia, finely situated 1,666ft.

above the sea, 3m. N.E. of its station on the railway between Chiusi and Orvieto. Pop. 2,492 (town); 8,914 (commune). It was the birthplace of the painter Pietro Vannucci (Perugino), and possesses several of his works, but none of the first rank. It has a Romanesque cathedral, a 13th century castle, and some picturesque buildings.

See F. Canuti, *Nella Patria di Perugino* (1926).

CITTÀ DI CASTELLO, a town and episcopal see of Umbria, Italy, in the province of Perugia, 38m. E. of Arezzo by rail (18m. direct), on the left bank of the Tiber, 945ft. above sea-level. Pop., 6,798 (town); 30,018 (commune). It occupies the site of the ancient *Tifernum Tiberinum*, near which the younger Pliny had a villa. Devastated by Totila, it soon recovered and was called *Castrum Felicitatis* in the 8th century; it oscillated between pope and emperor in the middle ages. Its plan is rectangular with walls (1518) and fine palaces of the Vitelli, its Renaissance lords. The cathedral was originally Romanesque and the Palazzo Comunale was built 1334-52. Some of Raphael's earlier works were painted for the churches of this town, but none of them remains there.

See Magherini Graziani, *L'Arte a Città di Castello* (1897).

CITTÀ VECCHIA or **CITTÀ NOTABILE**, a fortified city of Malta, 7 m. W. of Valletta, with which it is connected by railway. It lies on high ground, with extensive view. It is the seat of a bishop. The ornate cathedral is said to occupy the site of the house of the governor Publius who welcomed the apostle Paul; it was rebuilt after destruction by earthquake in 1693, and contains some rich stalls of the 15th century. In the rock beneath the city there are catacombs, partly pre-Christian, but containing evidence of early Christian burial. Below the church of San Paolo is a grotto, reputed to have sheltered the apostle. Roman buildings have been excavated in the town. About 2 m. from the town to the east is the Governor's palace, S. Antonio; and to the south is the palace of the grand masters of the order of St. John, in the public garden called Il Boschetto. Città Vecchia was the capital of the island till 1570. See also MALTA.

CITTERN (also CITHERN, CITHRON, CYTHREN, etc.), a mediæval stringed instrument of the guitar family (one of the many descendants of the ancient cithara), with a neck terminating

in a grotesque head of some kind, and twanged by fingers or plectrum. The popularity of the cittern was at its height in England and Germany during the 16th and 17th centuries. The cittern consisted of a pear-shaped body similar to that of the lute but with a flat back and sound-board joined by ribs.

According to Vincentio Galilei (the father of the great astronomer) England was the birthplace of the cittern which probably owed its popularity to the ease with which it might be mastered and used to accompany the voice. Hence it was one of four instruments generally found in barbers' shops, the others being the gittern, the lute and the virginal. The customers, while waiting, took down the instrument from its peg and played a merry tune to pass the time. The last development of the cittern before its disappearance was the addition of keys. The keyed cithara was first made by Claus & Co., of London, in 1783. The keys, six in number, were placed on the left of the sound-board, and on being depressed they acted on hammers inside the sound-chest, which, rising through the rose sound-hole, struck the strings. Sometimes the keys were placed in a little box right over the strings, the hammers striking from above.

It is evident that the kinship of cittern and guitar was formerly recognized, for during the 18th century the cittern was known as the English guitar to distinguish it from the Spanish instrument. From the cittern was developed the zither (*q.v.*).

FROM "OLD MUSICAL INSTRUMENTS" (METHUEN & CO.)

THE CITTERN, A MÆDIAEVAL INSTRUMENT BELIEVED TO BE OF ENGLISH ORIGIN

CITY. In Great Britain strictly speaking "city" is an honorary title officially applied to those towns which, in virtue of some pre-eminence (e.g., as being episcopal sees or great industrial centres), have by traditional usage or royal charter acquired the right to the designation. The official style of "city" does not necessarily involve the possession of municipal power greater than those of the ordinary boroughs, nor indeed the possession of a corporation at all (e.g., Ely). In the United States and the British dominions, on the other hand, the official application of the term "city" depends on the kind and extent of the municipal privileges possessed by the corporations, and charters are given raising towns and villages to the rank of cities. Both in France and England the word is also used to distinguish the older and central nucleus of some of the large towns, e.g., the *cit  * in Paris, and the "square mile" under the jurisdiction of the lord mayor which is the "City of London." In common usage, however, the word is loosely applied to any large centre of population, and in the United States any town, whether technically a city or not, is usually so designated, with little regard to its actual size or importance.

As the translation of the Greek *      * or Latin *civitas*, the word involves the ancient conception of the state or "city-state," i.e., of the state as not too large to prevent its government through the assembled body of the citizens, and is applied not to the place but to the whole body politic. From this conception both the word and its dignified connotation are without doubt historically derived. On the occupation of Gaul the Gallic states and tribes were called *civitates* by the Romans, and subsequently the name was confined to the chief towns of the various administrative districts. These were also the seats of the bishops. It is thus affirmed that in France from the 5th to the 15th century the name *civitas* or *cit  * was confined to such towns as were episcopal sees, and Du Cange (*Gloss. s.v. civitas*) defines that word as *urbs episcopalis*, and states that other towns were termed *castra* or *oppida*. How far any such distinction can be sharply drawn may be doubted. No definite line can be drawn between those English towns to which the name *civitas* or *cit  * is given in mediaeval documents and those called *burgi* or boroughs (see J. H. Round, *Feudal England*; F. W. Maitland, *Domesday Book and After*). It was, however, maintained by Coke and Blackstone that a city is a town incorporate which is or has been the see of a bishop. It is true that the actual sees in England all have a formal right to the title and the boroughs erected into episcopal sees by Henry VIII. thereby became "cities"; but towns such as Thetford, Sherborne and Dorchester are not so designated, though they are regularly incorporated and were once episcopal sees. In 1075 the bishop's see was transferred from Sherborne to Salisbury. After eight and a half centuries, by an order published in the *London Gazette* of Feb. 10, 1924, Sherborne was re-created a suffragan bishopric. On the other hand it has only been since the latter part of the 19th century that the official style of "city" has, in Great Britain, been conferred by royal authority on certain important towns which were not episcopal sees, Birmingham in 1889 being the first to be so distinguished. London contains two cities, one (the City of London) outside, the other (the City of Westminster) included in the administrative county.

For the history of the origin and development of modern city government see **BOROUGH** and **COMMUNE, MEDIAEVAL**.

BIBLIOGRAPHY.—For American cities, see: William B. Munro, *The Government of American Cities*, 4th ed. (1924); Chester C. Maxey, *An Outline of Municipal Government* (1924).

CITY CLERK, the chief clerical official of the cities of the United States performing most of the duties of an English town clerk. In cities under the council form of government he is usually elected either as a partisan candidate or candidate without regard to party lines. In cities under the commission or commission-manager form of government, he usually is appointed by the mayor subject to the approval of the commission, or is chosen by the commission. He may serve for an indefinite number of terms. The city clerk keeps the minutes of the meetings of the city council or commission. He also keeps all other city records, and in many States has authority to issue licences. He usually has a force of deputies appointed by him or by the

authority which appoints him, or selected by civil service regulations.

See Herman G. James, *Local Government in the United States* (1921); Chester C. Maxey, *An Outline of Municipal Government* (1924).

CITY GOVERNMENT. The authorities charged with city government are constituted upon one or other of the following principles: free local election of indigenous growth, as in Great Britain and as transmitted to her dominions overseas; a more or less complex mixture of free local election with central government appointment, as in most European countries; a somewhat intricate mixture of free local election with bureaucratic administrative method, exemplified practically throughout the United States. These principles are, however, alive throughout the ages and present in detailed application all the phenomena of change and development associated with the living organism. The history and form of municipal administration will be found under the titles of the various countries, and such special articles as **BABYLONIAN LAW**, **GREEK LAW**, **ARCHON**, **ECCLESIA**, **BOROUGH**, **MAYOR**, etc.

I. THE ENGLISH SYSTEM

Though keeping to the full the characteristic features of life, English city government is perhaps the least changed of any instrument of government in the world. Apart from measures of standardization, such as the Municipal Corporations Act, 1882, the city governments of England are the same in form to-day as they were 500 years ago. The municipal corporation, with its mayor, aldermen and councillors elected by the burgesses and its machinery of town clerk, surveyor and other paid officers is still to-day the staple form of authority by means of which an English city is governed; committees of elected members or councillors under whose orders the paid officers act are its medium. Life indeed has shown its existence rather in the expansion of object than in any change of form.

Many services, which a few years ago would by popular opinion have been unhesitatingly placed in the category of matters fit only for handling by private enterprise, are now treated as municipal services. Public health services are steadily enlarging to embrace treatment not only of material but of persons. Medical examination and treatment of school children are now municipal services, while tuberculosis and venereal disease are recognized, in addition to infectious diseases, as evils for the prevention and cure of which all the forces of the civic authorities must be mobilized. Gas and electricity services, the first of which in London is still in the hands of companies and the second of which is now dealt with by an authority constituted for the purpose, have, in Birmingham, Manchester and many other large cities, as well as in some of the metropolitan boroughs, long been within the acknowledged sphere of city government. Many of the larger cities, following the example of Glasgow and Manchester, regard the provision of traffic facilities in a broader sense than the mere provision of new or wider roads as of civic concern.

Spain.—The type of civic authority dealt with under this heading is not entirely confined to Great Britain. Spanish city government has developed strongly upon these lines and communes are administered by *ayuntamientos*, elected by registered male citizens and females who are heads of families in the legal sense above 23 years of age domiciled in the communes for at least two years, with a president or chairman (*alcalde*) appointed by the *ayuntamientos* from amongst its own members. It is true that there has always been a governor appointed by the state, who represents the state's authority in each province, but his duty as regards municipalities has been no more than to see that their actions do not overstep the powers granted to them. In 1924 the *estatuto municipal* was passed giving communes through their *ayuntamientos* the right to choose whatever organization best suits them. The statute also prescribes methods for determining the revenue and expenditure, as well as for the fixation of taxes, etc. Municipal accounts are not subject to approval by the state government, and *ayuntamientos* may form their own budgets.

This report was presented to the third international congress of towns and communes held in Paris in 1925.

II. THE MIXED SYSTEM

Under the second heading fall the city governments prevailing throughout Europe (except Spain) and their derivatives (including Spanish) in Asia, Africa and North and South America. Generalization on such a question is difficult and apt to be misleading but the following examples may safely be taken as typical. A separate section is given to the United States.

France.—For local government purposes France is divided into departments, arrondissements, cantons and communes. The local affairs of the commune are managed by the municipal council elected by male (over 21) suffrage for four years, but many of its decisions and especially its budget must be approved by the prefect of the department, who is a political official nominated by the minister of the interior and appointed by the president. On the other hand, a *conseil général* elected by male suffrage from business men in the cantons controls the departmental administration of the prefect. The municipal council elects from among its members a mayor who as executive head of the commune proposes the budget and supervises the police, revenue and public works, and appoints to or dismisses from communal offices. The mayor is also the agent of the government, and in his sphere of administration is charged with carrying out the laws of the country. Assistance is given to mayors by deputies (*adjoints*) elected by the municipal council and varying in number, according to the population of the commune, to not exceeding 12 (though in Lyons there are 17). The communal council draws up a list of *répartiteurs*, whose duty it is to apportion among the taxpayers the commune's share of direct taxes, but the actual selection from the list is made by the sub-prefect of the arrondissement. Direct taxes are imposed by the *conseil général* on the district councils (*conseils d'arrondissements*) who allot to each commune its share of these taxes.

Germany.—City authorities are empowered to do whatever is deemed necessary in the interests of the city, subject to nothing being done which is prohibited either by law or by the veto of higher authorities. Speaking generally, the powers exercised by the German municipality correspond fairly closely with those exercisable by its English counterpart, with the important additions that poor law relief and all the public services of gas, electricity, water and tramways are almost universally included.

The general form of city government in Prussia and Hesse is by way of (a) municipal council, which elects a chairman, substitute chairman and secretary or clerk who may or may not be a member of the council, (b) *magistrat*—an executive board consisting of unpaid and paid members, the latter being usually expert officials. The head of the *magistrat* is the burgomaster, who is appointed by the council; he is usually an expert and has frequently been successful in a similar position elsewhere. Like the American city manager, the office of burgomaster provides a professional career.

The exercise of the powers of the municipality is restricted first by the overriding authority of the minister of the interior; secondly, by the intervention on occasion of the *oberpräsident* of the province. He, too, is appointed by the state and corresponds to the French prefect, as he is also the local agent of the national

government.

A third form of control is by a district board (*Bezirksausschuss*) appointed by the provincial committee and composed of trained officials. They are a sanctioning authority and the arbiter between the municipal council and the *magistrat*. The part played by the state government as distinct from the national government is therefore considerable.

Netherlands.—The municipal councils (*raad*) are elected bodies varying in numbers in accordance with size of towns. The mayor or burgomaster is appointed by the sovereign but in supposed deference to the wishes of the council. The councils are elected for a four-year term. Executive powers are given to *wethouders* (six in large towns) chosen by the council, and as such paid salaries. The police are under the burgomaster, who is an expert civil servant rather than a citizen magistrate, often holds his position for life, and is well paid. Municipal self-rule is more complete than in France, though budgets have to be approved by executive committees ("deputed states") of provinces, and the "commissioner of the sovereign" has also a controlling influence, corresponding to that of the French prefect, though not so powerful.

Norway.—Oslo and Bergen have a governor (*fylkesmann*) appointed by the state, as they rank with counties. Other cities and towns are administered by a town council (*bystyre*) elected for three years, and an executive committee (*formandskap*) of one-fourth the number of the council. The chairman of the council is elected by the members of the council from their midst. These chairmen, with the governor of the county in which the municipalities are situated, meet annually, and decide upon the taxes, etc., to be raised in the various cities and towns. There is also a burgomaster appointed by the council but his work is mainly secretarial.

Since 1910 women over 23 years of age have had the suffrage and are eligible for office under the same conditions as men.

III. UNITED STATES

Lord Bryce's *American Commonwealth* (1888) marks the turning point in the constructive consideration of city problems in America. From the end of the Civil War in 1865 to 1888, the United States was engrossed in problems of national readjustment, reconstruction, transport and internal development. Municipal affairs, where not wholly neglected, were at low ebb and in the hands of selfish political organizations, whose interests were wholly those of personal aggrandizement and profit. Lord Bryce's criticism stung the country into consciousness of these shortcomings.

Philadelphia Conference.—A national conference on city government was held in Philadelphia in 1894, out of which grew the National Municipal League. There was no regular form of American municipal government, and the greatest diversity of types existed. The general tendency, however, was toward a Federal plan modelled on that of the national Government with a division of functions (legislative, administrative and judicial). Out of the league's efforts grew a "municipal programme," the fundamental features of which were:—

That every community should have the right of self-government in local affairs without the interference of outside governmental or party machinery.

That the city's public property in land, and especially its franchise rights, should be preserved unimpaired.

That all barriers should be removed that prevented the popular will from expressing itself freely and effectively.

That municipal administration should be conducted in the main by a class of public servants who by reason of experience and special training were particularly fitted for their official duties.

That official responsibility should be so placed, through simplification of governmental machinery and full publicity of accounts. And that the people could hold their public servants to the execution of the public will with the least possible delay and uncertainty.

Example of Galveston.—In the year in which this general programme was adopted (1900) the Galveston hurricane-flood nearly destroyed that city. Among other things swept away was the typical old-style mayor and council form of government, which was replaced by a commission of five men, appointed by the governor of Texas. This commission worked so swiftly and efficiently, and with so much less annual cost that, after the emergency passed, an attempt was made to continue it with a commission of five members, three appointed by the governor and two chosen by popular vote. A court decision declared such appointments to be unconstitutional, and the entire commission forthwith became elective. To the surprise of most observers, no demoralization ensued, and through successive elections changes in the personnel were slight.

In 1908 Des Moines, Ia., adopted the Galveston system, with the addition of the initiative, referendum, recall and non-partisan primary. This broader plan was even more widely copied than the Galveston plan. Among the larger cities (over 100,000 population) which adopted it were Buffalo (which has since abandoned it); Newark, N.J.; New Orleans; Jersey City; Portland, Ore.; St. Paul; Oakland, Calif.; Houston, Texas; Trenton, N.J.; Salt Lake City; Reading, Pa.; Fort Worth, Texas; Spokane; Kansas City, Kan.; 29 cities of over 50,000 population had adopted it by 1915, 67 of over 20,000 and 90 of over 10,000. Illinois leads in the number of commission-governed cities, followed by Texas, Kansas, New Jersey, Pennsylvania, Oklahoma, California, Michigan, South Dakota, Alabama, Louisiana, Tennessee and Florida.

City Manager System.—Few changes of importance were made in the Des Moines plan (except the addition of the preferential ballot first added by Grand Junction, Colo., 1909), until the appearance of the modification providing for a city manager. Operating under an old form of government, the council of Staunton, Va., in 1908 appointed a business manager. Later (1913) Dayton, O., after a disastrous flood, adopted the commission-manager form of government, the essential feature of which was a small council of five acting as a policy-determining body, and a city manager, to be elected by the council, to execute its policy. Out of this grew a city-manager form, which the National Municipal League recommended to charter-makers, then multiplying in great numbers, due to the growing dissatisfaction with existing conditions. This second "municipal programme" formally adopted by the National Municipal League in 1914, definitely embodied the city or commission-manager plan and later recommended that the council or legislative body be elected on the principle of proportional representation.

The city-manager movement is justly regarded as the ripest fruit of the movement for better municipal government. It embodies the short ballot, responsiveness to public opinion, concentration of executive power and responsibility, expert administration of city affairs and elimination of legislative control over the administrative—all essential principles of sound government practice. The success of the plan has been abundantly proved, although here and there expectations, because unreasonable, have not been met. Moreover, its application to an increasing number of cities is developing municipal policies as perhaps no other single factor has. City planning, zoning, budget-making, improved personnel and administration, more effective purchasing, the preparation of adequate and carefully devised plans for transportation, intelligent housing—all have been stimulated by utilizing experts in municipal affairs under the guidance of trained city managers.

On May 1, 1928, there were 364 cities and towns operating under a city-manager form of government: 288 by virtue of charter provisions, and 76 by virtue of ordinance provisions. These were distributed as follows: Michigan, 40; Florida, 36; California, 29; Texas and Virginia, 24 each; Oklahoma, 22; Ohio, 18; Pennsylvania, 16; Kansas, 15; Georgia, 12; Iowa and North Carolina, 11 each; New York and West Virginia, 8 each; Illinois and Tennessee, 6 each; Colorado, Oregon and Vermont, 5 each,

and 15 from 1 to 4 each. The cities over 20,000 operating under this form of government are Cleveland (769,841); Cincinnati (401,247); Kansas City, Mo. (324,410); Rochester, N.Y. (295,750); Norfolk, Va. (159,080); Dayton, O. (152,559); Grand Rapids, Mich. (137,634); Fort Worth, Texas (106,492); Oklahoma City, Okla.; Knoxville, Tenn.; San Diego, Calif.; Wichita, Kan.; Sacramento, Calif.; Springfield, O.; Wheeling, W. Va.; Portsmouth, Va.; Berkeley, Calif.; Tampa, Fla.; Long Beach, Calif.; Roanoke, Va.; Niagara Falls; Jackson, Kalamazoo and Bay City, Mich.; Pasadena, Calif.; Greensboro, N.C.; Lima, O.; Beaumont, Texas; Kenosha, Wis.; Charleston, W. Va.; Miami, Fla.; Portland, Me.; Stockton, Calif.; Dubuque, Ia.; San Jose, Calif.; Muskegon and Pontiac, Mich.; Auburn, N.Y.; Waco, Texas; Newport News, Va.; Austin, Texas; Columbus, Ga.; Lynchburg, Va.; West Palm Beach, Fla.; Colorado Springs, Colo.; Muskogee, Okla.; Phoenix, Ariz.; Alameda, Calif.; Newburgh and Watertown, N.Y.; East Cleveland, O.; New London, Conn.; Middletown and Sandusky, O.; Durham, N.C.; Daytona Beach, Fla.; Lakeland, Fla.; St. Augustine, Fla.; Petersburg, Va.

Progress in Recent Years.—There can be no lasting improvement in the personnel of city officials until the short ballot becomes an established fact. This change will come less quickly than the others because of the "vested interests" of the great political organizations, which will yield with the greatest reluctance, for the short ballot means the substitution of citizen management for party organization. The city-manager form, however, is an embodiment of the short ballot principle and its growth represents progress along those lines.

Prof. Frank Parsons, in summing up the municipal activities of American cities, declared the following subjects had been held to be proper public purposes and proper subjects of municipal ownership and control: roads, bridges, sidewalks, sewers, ferries, markets, scales, wharves, canals, parks, baths, schools, libraries, museums, hospitals, lodging houses, poor-houses, police, jails, cemeteries, prevention of fire, supply of water, gas, electricity, heat, power, transportation, telegraph and telephone service, clocks, skating rinks, musical entertainments, exhibitions of fireworks, tobacco warehouses, employment offices.

Zoning, City and Regional Planning.—According to the Federal census of 1920, America had become preponderantly urban, over 50% of the population being reported as living in cities. The municipal problem is, therefore, an outstanding one, and questions of regional planning and city and county consolidation have become of increasing importance. There has been a remarkable and wide-spread development of the movement for city, metropolitan and regional planning and zoning. According to the figures gathered by the U.S. Chamber of Commerce (1928), there are 409 city-planning commissions in the United States, 183 zoning commissions and 14 regional plan commissions. There are 569 zoning ordinances in operation of which 348 are described as comprehensive; 181 comprehensive city plans, 148 comprehensive thoroughfare plans, 216 park and playgrounds plans and 14 transportation terminal and grade separations plans, completed. New York State leads with zoning commissions (95) followed by New Jersey (75); Illinois (59); California (52); Ohio and Pennsylvania (30 each); Wisconsin (28) and Michigan (23). In the matter of city-planning commissions Massachusetts leads with 31; New York and Pennsylvania follow with 12 each; Illinois and Ohio, 11 each; Michigan and Wisconsin 10 each. As an indication of the rapid growth of this movement it is to be noted that 23 States in 1927 adopted the Standard State Zoning Enabling act under which cities may adopt zoning regulations. This Standard act was recommended by an advisory committee on zoning appointed by Secretary of Commerce Herbert Hoover. Coincident with many of these city and regional plans for physical improvements, accompanying financial programmes are being worked out.

CITY MANAGER, in the United States an official chosen by the city council or commission and having general managerial functions over the affairs of the city. The position of city manager was first created in 1909 by the council of Staunton, Va., a city then under the mayor and council form of government. Sumter, S.C., in 1912, was the first city to adopt the commission-manager plan of government. Among the early adoptions was that of Dayton, O., in 1910, which served as a model for other cities. The city manager is responsible only to the council or commission which selects him, and he is not in any case elected by the voters as are the mayors and councilmen in the council form of government, and the mayors and commissioners in the commission and commission-manager plans. The city manager need not be a resident of the city when chosen, and some such managers have gone from one city to another to accept increased emoluments. In many States the duties of the city manager are prescribed by act of the State legislature. In such cases he usually appoints all of the city officials, except the city clerk, subject to such civil service regulations as may be in force. In other States, cities choose managers as the result of ordinances of the city council or commission, which means the adoption of the manager form only in a modified form. In such cases, the powers of the city manager are not likely to be as great as when his duties are defined by the legislature. In 1912, three cities appointed managers; in 1913, seven; in 1914, 17; in 1915, 23; in 1916, 14; in 1917, 15; in 1918, 27; in 1919, 28; in 1920, 33; in 1921, 52; in 1922, 37; in 1923, 34; in 1924, 17; in 1925, 25; in 1926, 20; and in 1927, 12, making a total of 365 appointments of which 295 were by charter and 71 by ordinance.

See Herman G. James, *Local Government in the United States* (1921).

CITY PLANNING: see TOWN PLANNING.

CIUDAD BOLÍVAR, an inland city and river port of Venezuela, capital of the State of Bolívar, on the right bank of the Orinoco river, 240m. above its mouth. Pop. (1926) about 15,000. It stands upon a small hill some 125ft. above sea-level, and faces the river where it narrows to a width of less than half a mile. It is the commercial centre of the great Orinoco basin. The mean temperature is about 83° F. The city has regular steamship communication with the lower Orinoco, Port of Spain and the Caribbean coast of Venezuela. During the rainy season small steamers run far up the river. The principal exports from this region include cattle, horses, mules, tobacco, cacao, rubber, tonka beans, bitters, hides, timber and many valuable forest products. The town was founded by Mendoza in 1764 as San Tomás de la Nueva Guayana, but its location at this particular point on the river gave to it the popular name of *Angostura*, the Spanish term for "narrows." This name was used until 1849, when that of the Venezuelan liberator was bestowed upon it. Ciudad Bolívar played an important part in the struggle for independence and was for a time the headquarters of the revolution. The town suffered severely in the

fight for its possession, and the political disorders which followed greatly retarded its growth.

CIUDAD DE CURA, an inland town of the State of Aragua, Venezuela, 55m. S.W. of Caracas, near the Lago de Valencia. Pop. estimate 13,000. The town stands in a broad, fertile valley, between the sources of streams running southward to the Guárico river and northward to the lake, with an elevation above sea-level of 1,598ft. Traffic between Puerto Cabello and the Guárico plains has passed through this town since early colonial times, and has made it an important commercial centre, from which hides, cheese, coffee, cacao and beans are sent down to the coast for export; it bears a high reputation in Venezuela for commercial enterprise. Ciudad de Cura was founded in 1730, and suffered severely in the war of independence.

CIUDAD JUÁREZ, formerly EL PASO DEL NORTE, a northern frontier town of Mexico, in the State of Chihuahua, 1,223m. by rail N.N.W. of Mexico City. Pop. (1910) 10,621; (1921) 19,457. Ciudad Juárez stands 3,800ft. above sea-level on the right bank of the Rio Grande del Norte, opposite the city of El Paso, Texas, with which it is connected by bridges. It is the northern terminus of the Mexican Central railway, and has a large and increasing transit trade with the United States, having a custom-house and a United States consulate. It is also a military post with a small garrison. The town has a straggling picturesque appearance, a considerable part of the habitations being small adobe or brick cabins. The town was founded in 1681-82; its present importance is due entirely to its position on the border and the railway into the interior. It was the headquarters of President Juárez in 1865, and was renamed in 1885 because of its devotion to his cause.

CIUDAD REAL, a province of central Spain, formed in 1833 of districts taken from New Castile, and bounded on the north by Toledo, north-east by Cuenca, east by Albacete, south by Jaén and Cordova and west by Badajoz. Pop. (1920) 427,365; area, 7,620sq.m. Ciudad Real is occupied in the east and centre by extensive high plains forming part of the region known as La Mancha (*q.v.*) and rising on the south-east to low hills. The west consists of broken hilly country bordered on the south by the parallel ridges of the Sierra de Alcudia and by the Sierra Madrona, foreranges of the Sierra Morena. The province is drained, except on the south-east, by the Guadiana river which traverses it from east to west and receives several tributaries, notably the Gígüela, Zánacara and Bullaque on the right and the Azuel and Jabalón on the left.

The climate on the plains is oppressively hot in summer, and in winter bitterly cold winds prevail. The rainfall is scanty and prolonged droughts are common. Forests occur only on the higher ground in the west. The vegetation on the La Mancha plains is limited to poor pasture. Cereals, saffron, the olive and vine are cultivated, but agricultural development is hindered by the scantiness of the population, the aridity and poverty of the soil, the want of proper irrigation and the occasional ravages of locusts. Large numbers of sheep and goats, however, are reared on the plains and Ciudad Real is famous for its mules. Pigs are kept in the oak forests of the west, and cork is an important product of this region. Coal is mined round Puertollano, lead in various districts, and important mercury deposits at Almadén. There is no other industrial development. The roads are insufficient and ill-kept, especially in the north-west where they form the sole means of communication. The Madrid-Lisbon railway passes through the capital, Ciudad Real, and through Puertollano, where there is a branch line to San Quintín. Farther east, the Madrid-Lináres railway passes through Alcázar de San Juan, junction for the Albacete line, and Manzanares and Valdepeñas, where branch lines link it with Ciudad Real and Puertollano respectively. There is also a branch in the north-east to Tomelloso.

The principal towns, Ciudad Real (pop. 1920, 18,991), Valdepeñas (25,218), Tomelloso (21,413), Puertollano (20,083), Alcázar de San Juan (16,117), Manzanares (15,846), Almodóvar del Campo (12,635) and Almadén (9,829), are described in separate articles. Almagro (8,701), famous for its lace, and Daimiel (16,198) a market centre of La Mancha and site of a

military aerodrome, belonged in the middle ages to the knightly order of Calatrava, formed in 1158 to keep the Moors in check. Campo de Criptania (12,745) and La Solina (10,971) are other market towns. Education is very backward. (See also CASTILE.)

CIUDAD REAL, a town of central Spain, capital formerly of a Mancha and since 1833 of the province described above. It lies 107m. S. of Madrid, on the Madrid-Badajoz-Lisbon and Ciudad Real-Manzanares railways. Pop. (1920) 18,991. Ciudad Real, situated on a wide plain, between the river Guadiana in the north and its tributary the Jabalón on the south, offers little of interest beyond its lofty Gothic cathedral, built without aisles. It is the market for the cereals, oil, wine, potatoes and figs produced with irrigation on the surrounding plain. Ciudad Real was founded by Alfonso X. of Castile (1252-84), and fortified by him as a check upon the Moorish power. Its original name of Villarreal was changed to Ciudad Real by John VI. in 1420. It is said to have suffered greatly, especially in the loss of its flourishing leather industry, by the expulsion of the Moriscos in the 17th century. During the Peninsular War a Spanish force was defeated here by the French, on March 27, 1809.

CIUDAD RODRIGO, a town of western Spain, in the province of Salamanca. It is situated on an eminence on the right bank of the river Agueda, 13½m. E. of the Portuguese frontier, and on the railway from Salamanca to Coimbra in Portugal. Pop. (1920) 8,761. Ciudad Rodrigo is an episcopal see, and was for many centuries an important frontier fortress. It was founded in the 12th century by Count Rodrigo González and named after him, but remnants of a Roman aqueduct and bridge indicate that it occupies the site of a Roman settlement. The 12th century cathedral, with fine cloisters and carved portico, was disfigured by additions in 1538 and has suffered during sieges from its position almost astride the walls. During the Peninsular War, it was captured by the French under Marshal Ney, in 1810; but on Jan. 19, 1812, it was retaken by the British under Viscount Wellington, who, for this exploit, was created earl of Wellington, duke of Ciudad Rodrigo, and marquess of Torres Vedras, in Portugal. (X.)

Siege of Ciudad Rodrigo, 1812.—For the operations preceding and following the siege of Ciudad Rodrigo in 1812 see PENINSULAR WAR. Having insufficient troops to provide a covering force Wellington decided to use the element of surprise. He waited till both armies were scattered in winter quarters, made all his preparations in secret, and then suddenly, on Jan. 8, appeared before the town. Ciudad Rodrigo lies on the right bank of the Agueda and in 1812 its fortifications were modern and formidable, but it was commanded on the north by a hill, the Great Teson, which, crowned by a strong redoubt, rose to a height of 150ft., only 600yd. from the walls. Between this hill and the town lay a slightly lower ridge, the Little Teson, which was flanked at its eastern end by the Convent of San Francisco, at its western by that of Santa Cruz. The very night of his arrival Wellington stormed the redoubt on the Great Teson and at once began his preparations for an intensive siege. The weather was terribly severe, so that the troops in the trenches had to be relieved every 24 hours, but the men worked with great speed and enthusiasm. Within six days the British had dug a parallel and constructed batteries for 32 guns on the Great Teson, had sapped across the low ground and dug a parallel within assaulting distance on the Little Teson, and had stormed the convents which flanked it. For five days a furious bombardment was maintained, the enemy replying with equal vigour. By Jan. 19 two breaches had been made in the walls and, though the counterscarp had not been destroyed nor the enemy's guns silenced, Wellington gave orders for an assault. The main breach, at the northern corner of the fortifications was to be stormed by the 3rd Division; the lesser breach, 200yd. to the east, by the Light Division. Pack's Portuguese were to make a feint attack upon the San Pelayo gate at the other side of the town. At 7 P.M. on the 19th Campbell's Brigade of the 3rd Division entered the ditch at the south-west corner of the fortress, with orders to scale the outer wall and clear the left flank of the main breach. Their actual entry was premature and the garrison opened fire while the other attacking

troops were still in their assembly trenches. The storming columns at once dashed forward. The 3rd Division was checked at the main breach by a land mine, but quickly drove the defenders back to a retrenchment behind the breach, which for a time held them back. The Light Division met with less opposition and, pouring through the lesser breach, cleared the way for their comrades on the right. The garrison quickly surrendered, but the storming troops got out of hand and for the rest of the night plundered, drank, burnt, and murdered; only at daylight was order restored. The siege cost Wellington 1,000 casualties, half in the assault, but 1,500 prisoners and 150 guns fell into his hands. Marmont only received definite news of the siege on the 15th; by the time he had collected his army the town had fallen. (H. L. A.-F.)

CIUDAD VIEJA, Guatemala, a village near Antigua Guatemala (*q.v.*) which marks the site of the first capital of the Spanish Captain Generalcy of Guatemala. The population is about 200, but the village still contains the ancient church, erected in 1543, and claimed by the Guatemalans to be the oldest church building in America excepting the cathedrals of Mexico and Lima, Peru. The original city of Guatemala was founded on this site by Pedro de Alvarado in 1527, and here he built a palace where his widow, Beatrice, who ruled after him as governor of the province, was killed; a few arches and walls remain of this palace. In 1541, as the result of an earthquake, the crater of the volcano now known as *Agua* (water) was cracked and the old city was overwhelmed with the flood of water held in the crater; the lower floors of the old houses, filled with mud and silt in that catastrophe, form the foundations of the present huts of the village. Following this disaster, the capital was moved to the site now known as Antigua Guatemala, whence it was in turn removed, as a result of another earthquake in 1773, to the present site of the capital, Guatemala la Nueva (*q.v.*).

CIVERCHIO, VINCENZO, an early 16th century Italian painter, born at Crema. There are altar-pieces by him at Brescia, and at Crema the altar-piece at the duomo (1509) is his work. His "Birth of Christ" is in the Brera, Milan; and at Lovere are other of his works dating from 1539 and 1540.

CIVET, or, properly, CIVET-CAT, the name given to the more typical members of the *Viverridae* (see CARNIVORA), which are characterized by the presence of a deep pouch near the genital organs into which a fatty, yellowish substance, known as civet

FROM "ROYAL NATURAL HISTORY" (WARNE)
CIVET, A CAT-LIKE ANIMAL, VALUED FOR A GLANDULAR SECRETION USED FOR PERFUME

and having a strong musky odour, is secreted. Several species are known. The African civet (*Viverra civetta*) measures 3-4½ ft. in length, of which a third is tail, and stands 10-12 in. high. The hair is long, forming an erectile ridge down the middle of the back; in colour it is dark grey with black bands and spots. The animal is nocturnal and largely carnivorous; it climbs trees with agility. It is kept in captivity (where, however, it never becomes tame) for the civet, the larger quantity coming from the male and being scraped out with a spoon twice a week. The zibeth (*V. zibetha*) extends from Arabia to India and several East Indian islands. Other species occur in India, China and Malaya. The odorous principle (a ketone) has been isolated and named libethone. Civet is used in perfumery for blending scents; its medicinal use has practically been discontinued.

CIVICS, in its broadest signification, may be taken to include the activities of the citizen in his relationship to the State and society in general. Formerly it meant the study of civil Government. "Civics" is defined as follows: "The science and consideration of the structure and administration of local, state and national government; of the development in the public mind of the will for constructive, intelligent and healthful participation in the work which governments—local, State and national—are empowered by the people to perform; and of the development of the procedures and processes which make for the greatest good of

the greatest number in the governmental and group relations of all social units." "Civics" embraces much more than a study of or dissertation on structures and functions, or a general interpretation of laws applying to these. It includes public-mindedness; the creation of right attitudes toward public duties; the formation of habits of helpful, constructive, participating citizenship; the development of activities which result in effective participation in good government; the consideration and application of procedures and processes which will result in the greatest good for the greatest number in all social units, big or little. The more modern textbooks on civics make the formal study of civil government only a part, and far from the largest part of their treatment. They teach the essential facts concerning sanitation; personal and community hygiene; fire prevention; care of the water supply; and a long list of other public activities. Whatever affects the well-being of social co-operative units is considered a part of civics even more than the purely governmental phases of the handling of such units.

In an address before a Congressional committee which had under consideration the operations of the U.S. Housing Corporation, the secretary of the American Civic Association, Harlean James, made this distinction between a social worker and a civic worker:—"A social worker deals with those persons who fall below the level of self-support either financially, physically or morally, and this holds true even when an effort is exerted to prevent any of these catastrophies. The civic worker deals with those persons who are sufficiently above the level of self-support financially, physically, mentally and morally to be in a position to contribute to the improvement of the community. Community improvement may be accelerated by good governmental machinery, but it is not the inevitable result of reform in municipal, county or state forms of government." A well-known writer of books under this heading, Mabel Hill, described "civics" as it is presented in high schools and junior colleges, as a study of the "social life in municipalities," and that life includes in its social relationships the Government of the town and city, the State and Federal Government, the institutions, social and ethical, as well as political, and sometimes, though not by any means always, would include religious institutions. Such a survey of municipal life, whether in the small manufacturing village or crowded metropolis gives opportunity to touch upon the theory of present government and the possibilities of changes that may occur because of trade unions. Likewise, "civics" should include the problem of the rural town and its relation to public service through agricultural interests; but above all, the teaching of "civics" should be a presentation of insistent opportunity for practice of the laws of sound citizenship and the ideals of the better citizenship for the future.

Sundry national, State and local volunteer organizations, especially in the United States, have the word "civics" in their titles. One of the oldest of these, the National Civic Federation, has an elaborate programme of activities, ranging from international relations to the individual voter, including economic and industrial questions and the relation of capital and labour. It grew out of the old Chicago Civic Federation, which was originally just what its name implied, a federation of local bodies interested in city or civic affairs. The American Civic Association which was formed of the merger of the American Park and Outdoor Art Association and the American League for Civic Improvement is concerned with the improvement of physical conditions in city, State and nation.

Generally speaking at the present time civic organizations are motivated by the broader idea of civics. Their objectives are no longer of a strictly political nature; their objectives now include the well being, physical and economic as well as political, of the individuals in the social unit. This broader meaning in practice of the word "civics" is largely due to the modern textbooks on the subject. (C. R. W.)

CIVIDALE DEL FRIULI, a town of Venetia, Italy, province of Udine, 10m. E. by N. by rail from the town of Udine; 453ft. above sea-level; it was the ancient Forum Iulii. Pop. (1921) 4,220 (town); 11,409 (commune). The river Natisone

forms a picturesque ravine here. The cathedral of the 15th century contains an octagonal marble canopy with sculptures in relief, with a font below it belonging to the 8th century. The museum contains Roman and Lombard antiquities, mss. and gold, silver and ivory objects formerly belonging to the chapter. The small church of S. Maria in Valle belongs to the 8th century, and contains fine decorations in stucco probably of the 12th century. The fine 15th-century Ponte del Diavolo leads to the church of S. Martino, which contains an altar of the 8th century with reliefs executed by order of the Lombard king, Ratchis. At Cividale was born Paulus Diaconus, the historian of the Lombards in the time of Charlemagne. A railway runs to Caporetto (16m.).

The Roman town of Forum Iulii was founded either by Julius Caesar or by Augustus, when the Via Iulia Augusta was built through Utina (Udine) on its way north. After the decay of Aquileia and Iulium Carnicum (Zuglio) it became the chief town of the district of Friuli and gave its name to it. The patriarchs of Aquileia resided here from 773 to 1031, then returned to Aquileia, and finally in 1238 removed to Udine. This last change of residence was the origin of antagonism between Cividale and Udine, terminated by their surrender to Venice in 1419 and 1420 respectively.

See G. Fogolari, *Cividale del Friuli* (Bergamo, 1906), well illustrated; *Memorie Storiche Forogiuliesi, passim* (Udine, 1905, sqq.—in progress).

CIVIL ENGINEER. When, in the 18th century, attention began to be given in England to such works of public value as roads, canals, harbours, docks, and lighthouses, the regulation of rivers, the production of iron by improved methods, and the construction of steam engines and of the machinery called forth by that new source of motive power, there arose men of great natural gifts, either with little technical training but great practical intelligence and skill, such as Brindley, or of equal practical capacity coupled with scientific attainments, such as Smeaton and Watt. These men applied to beneficent purposes the mechanical and constructional arts which previously had formed almost entirely the vocation of the military engineer, and they called themselves "engineers"; but Smeaton, seeing the inappropriateness of assuming a title hitherto belonging to military men, adopted the title "civil engineer," to make it clear that he was a civilian practitioner of those arts.

It was with this conception of the civil engineering profession that the Institution of Civil Engineers was founded. A royal charter of incorporation was granted to the institution on June 3, 1828. Before applying for the charter, the Society drew up a definition of the profession, "the art of directing the great sources of power in Nature for the use and convenience of man."

Many societies have since arisen having for their object the advancement of particular branches of engineering work, but the institution adheres to the conception of civil engineering held by its founders, and admits to its ranks any engineer who is adequately trained and experienced in the design and execution of any works or machinery instrumental in the application of sources of power for the benefit and convenience of mankind. The roll of the institution in 1928 numbered upwards of 10,000. Its house in Great George street, Westminster (the third building which it has occupied in that street), was built in 1912-13.

Specialization has brought about separate grouping of those interested in mechanical, electrical mining, etc., engineering. Underlying all groups is the work of the civil engineer, whose field particularly is that of structures. Foundations, simple or extremely complicated, are within his realm. He designs and supervises the construction of bridges and great buildings, tunnels, dams, reservoirs and aqueducts; he brings water to the centres of population and disposes of their wastes. He irrigates the desert and reclaims the swamps. He lays out, constructs and maintains highways and railroads, digs canals, regulates rivers, deepens harbours, builds lighthouses and constructs wharves and piers. He measures the earth's surface and the objects on it, and charts the resulting data. The work is frequently of a very definitely pioneering character, involving protracted physical effort. The civil engineer must have a scientific attitude of mind, and should

have imagination, initiative, accuracy and good judgment, trained by special study. He should be able to work with men as well as with materials, and he should have administrative ability. In the United States with over 100 million inhabitants, probably 75,000 persons would call themselves civil engineers.

The American Society of Civil Engineers, founded in 1852, admits engineers from various fields. It has a membership of about 14,000 and is an important engineering institution.

CIVILIS, CLAUDIUS, or more correctly IULIUS, a Batavian leader of the German revolt against Rome (A.D. 69–70). He had served as a Roman auxiliary. During the disturbances that followed the death of Nero, he induced the Batavi to rebel, under the pretence of assisting Vespasian. The neighbouring Germans joined the revolt. The Roman garrisons near the Rhine were driven out, and 24 ships captured. Two legions were blockaded in Castra Vetera (near the modern Xanten), and the survivors were finally massacred. Eight cohorts of Batavian veterans joined their countrymen, and the troops sent by Vespasian to the relief of Vetera threw in their lot with them. The result of these accessions to the forces of Civilis was a rising in Gaul. The Roman generals were murdered (A.D. 70), and the whole of the Roman forces were induced by two commanders of the Gallic auxiliaries (Julius Classicus and Julius Tutor) to revolt from Rome and join Civilis. Most of Gaul declared itself independent, and the foundation of an empire of the Gauls was contemplated. Vespasian resolved to take strong measures for the suppression of the revolt. The arrival of Petillius Cerialis with a strong force awed the Gauls and mutinous troops into submission; Civilis was defeated at Augusta Treverorum (Trier, Trèves) and Vetera, and forced to withdraw to the island of the Batavians. He finally came to an agreement with Cerialis whereby his countrymen obtained certain advantages, and resumed amicable relations with Rome. From this time Civilis disappears from history.

BIBLIOGRAPHY.—The chief authority for the history of the insurrection is Tacitus, *Histories*, iv., v., whose account breaks off at the beginning of Civilis's speech to Cerialis; also Josephus, *Bellum Judaicum*, vii. 4. See also Merivale, *Hist. of the Romans under the Empire*, ch. 58; H. Schiller, *Geschichte der römischen Kaiserzeit*, bk. ii. ch. 2. § 54 (1883); B. Henderson, *Civil War and Rebellion in the Roman Empire* (1908); Mommsen, *Provinces of the Roman Empire* (ch. iv.), trans. Dickson (1909).

CIVILIZATION. This Encyclopædia is in itself a description of civilization, for it contains the story of human achievement in all its bewildering developments. It shows what men during hundreds of thousands of years have been learning about themselves, their world and the creatures which share it with them. They have reached out into remote space and studied nebulae whose light reaches them after a million years; they have, on the other hand, dissected atoms and manipulated electrons as they might handle pebbles. In the present magnificent series of volumes man's inventions are reviewed from the rudest chipped flint to the most delicately adjusted microscope; his creation of multiform beauties of design, colour and word, his ways of dealing with his fellows, his co-operations and dissensions; his ideals and lofty aspirations, his inevitable blunders and disappointments; in short, all his gropings, disheartening failures and unbelievable triumphs are recalled.

Several thousand contributors have been brought together to do each his special part in writing some thirty-five million words on what mankind has hitherto done and said. It might therefore seem at first sight superfluous, and indeed impossible, to treat civilization itself as a separate topic in a few pages. But there is danger that owing to the overwhelming mass of information given in these volumes certain important underlying considerations may be lost sight of. There are highly significant questions concerning the nature and course of human development, the obstacles which have lain in the way of advance; the sources of success and frustration, which could hardly be brought together in dealing with any of the special aspects of human culture. Accordingly an attempt will be made under this caption to scan civilization as a single, unique and astonishing achievement of the human species.

To begin with, it is a startling fact that civilization, which sets off man in so astounding a manner from all other animals, should

only lately have begun to be understood. We are immersed in it from infancy; we take it for granted, and are too near it to see it, except in this detail and that. Even to-day, with all our recently acquired knowledge, those who strive most valiantly in imagination to get outside civilization so that they may look upon it dispassionately and appraise it as a whole, are bewildered by its mysteries. As for the great mass of intelligent people, they still harbour many ancient illusions and misapprehensions from which they can only be weaned with great reluctance.

The object of the present article is to describe the newer ways of viewing civilization, its general nature, origin, progress, transmission and chief developments, in the light of information which has been accumulating during the past fifty or sixty years. The study of man himself has been revealing quite as many revolutionary facts and hypotheses during the past half century as the scientific investigation of the world in which he lives. The history of human achievement has been traced back, at least in vague outline, hundreds of thousands of years; man's original uncivilized nature and equipment have been studied and compared with the behaviour of his nearer relatives; new conjectures have emerged in regard to the functioning of speech and the nature and origin of human reasoning; careful investigations of primitive civilizations have cast great light on more complicated ones; the tremendous importance of childhood and its various implications in the development of civilization have been elaborated.

These and many other discoveries conspire to recast our conception of civilization, its past progress and its future possibilities.

It is instructive to note that the word civilization is by no means an old one. Boswell reports that he urged Dr. Johnson to insert the term in his dictionary in 1772, but Johnson refused. He preferred the older word "civility." This, like "urbanity," reflects the contempt of the townsman for the rustic or barbarian; it is an invidious term, although in a way justified by the fact that only where cities have grown up have men developed intricate civilizations. The arduous and dispersed tasks of the hunter, shepherd and peasant folk do not afford the leisure, or at least the varied human contacts, essential to the generation of new ideas and discoveries. But modern anthropologists have pointed out that peoples without cities, such as the tribes of Polynesia and the North American Indians, are really highly "civilized," in the sense that upon sympathetic examination, they are found to have subtle languages, ingenious arts, admirably suited to their conditions, developed institutions, social and political; religious practices and confident myths, no better and no worse substantiated than many that prevail to-day among the nations of Europe. All these betoken and presuppose a vastly long development. Among English speaking people the first to point this out clearly was E. B. Tylor, who published his famous *Primitive Culture* in 1871, the same year in which Darwin's *Descent of Man* appeared. These two books would alone have served, by different approaches, to give the word civilization a far more profound meaning than it had ever had before.

NEW CONCEPTION OF CIVILIZATION

There could be no real understanding of the fundamental characteristics of civilization until the fact was well established and digested that could we trace back man's lineage far enough we should find it merging into that of wild animals, without artificial shelters, clothes or speech; dependent for sustenance on the precarious daily search for food. It requires a considerable effort of the imagination to picture the human race without these seeming necessities of even primitive civilization. Without fire and tools men must have existed as did a wild girl discovered near Châlons, France, in 1731. She possessed a monkey-like agility which enabled her to catch birds and rabbits; these she skinned with her nails and gobbled raw, as would a dog. She delighted to suck the blood from living pigeons, and had no speech except hideous screams and howls.

This conception of man's former animal existence is gradually supplanting the older one, based upon ancient Hebrew tradition, that the first man and first woman were special creations with fully developed minds, speech and reason, which enabled them forthwith to dress the garden in which they found themselves, to

name its animal denizens, and to talk with one another, and with God himself in the cool of the evening. This view is still passively accepted by an overwhelming majority of Americans and Europeans and is at present hotly defended by a powerful group in the United States.

The former assumption was that man was *by nature* endowed with a *mind* and with *reason*. These distinguished him sharply from the animals, which did wondrous things it is true, but not as a result of reason. Their behaviour was guided, it was argued, by instinct. Darwin says that "the very essence of an instinct is that it is followed independently of reason." But if we agree, as manifold evidence seems to force us to do, that long, long ago men behaved and lived like wild animals, are we not forced to ask if they did not live wholly according to what Darwin calls "instincts"? And if once upon a time our ancestors lived solely by their animal equipment, did they as yet have a mind and reason? May not the human mind be something that has very gradually developed as a result of man's peculiar animal make-up and capacities? May not his reason be but another name for his slowly accumulated knowledge and beliefs and his ways of dealing with them and building upon them? In any case the discovery that our ancestors once lived like wild animals raises entirely new and difficult questions as to the nature, origin and interpretation of those powers of his known as mind and reason, which have enabled him to seek out those inventions and come upon beliefs and practices which have produced in the aggregate civilization.

In short, it seems to be more and more apparent that mind and reason were not part of man's original equipment, as are his arms and legs, his brain and tongue, but have been slowly acquired and painfully built up. They are themselves *inventions*—things he has come upon. Like other inventions *they are part and parcel of civilization*—not innate in man but dependent for their perpetuation on education in the widest sense of that term. This is so novel an idea that many readers may find it difficult to grasp, but when grasped it alters one's whole estimate of human progress. We ordinarily think of civilization as made up of mechanical devices, books and pictures, enlightened religious ideas, handsome buildings, polite conduct, scientific and philosophical knowledge, social and political institutions, ingenious methods of transportation and the rest. We think that all these things are due to man's possession of a mind, which no animal has, and as a result of the exercise of reason. In a way this is true enough, only we must reconceive mind and reason and regard them just as truly a part of the gradual elaboration of civilization as a House of Commons or a motor car, and quite as subject to improvement. At the risk of making a seemingly irrelevant philosophical digression, which is really most essential to a modern understanding of civilization, something may be said of the newer conception of mind and its variant, reason.

The word mind was originally a verb, not a noun; it meant action, not a thing or agent. It was remembering and purposing, and taking note of—as for instance "I minded"—that is, remembered, or paid attention to, or was concerned by. But as time went on philosophers made a noun of the good old verb. It was conceived as that incorporeal substance which was the seat of a person's consciousness, thoughts, feelings, and especially of his reasoning. The body was set over against the mind whose orders it was supposed to execute. The Scottish philosopher of common sense, Reid, says explicitly that "we do not give the name of mind to thought, reason or desire; but to that power which both perceives and wills." Even John Stuart Mill says in his *Logic* that "mind is the mysterious something which feels and thinks."

Recently there has been a tendency to reduce the noun mind once more to a series of verbs—desiring, remembering, feeling, thinking, distinguishing, inferring, planning—and to regard the assumption of "a mysterious something" as unfounded, unnecessary and a serious embarrassment. Relieved of this embarrassment it is possible to begin to bridge the gulf between the original behaviour of the human race and that of mankind to-day. Descartes and all the older philosophers believed that man had always had a mind as good as theirs. They sought to tell him how to employ it in the pursuit of truth. Mind was to them a sort of

divine instrument, conferred solely upon man, that could be sharpened and efficiently used by following the laws of logic; but they could not think of it as something accumulated, so to speak, through the many thousands of years since man made his first contributions to the upbuilding of civilization.

The way is now cleared for a new view of civilization which would not have been possible 50 or 60 years ago. Civilization is no longer contrasted with "rusticity," "barbarity" or "savagery," but with man's purely animal heritage. Modern men are still animals, they have to eat and sleep, protect themselves from the inclemencies of the weather, and defend themselves from attacks of their fellow creatures and other animals, and to rear a new generation, if the species is to be perpetuated. They closely resemble kindred animals in much of their physical structure, in their important organs, breathing, digestion and the circulation of their blood. All these peculiarities are hereditarily transmitted no matter how much or how little men may be civilized. On the other hand, civilization—language, religion, beliefs, morals, arts and manifestations of the human mind and reason—none of these can be shown to be handed down as biological traits. They can only be transmitted to a new generation by imitation or instruction.

All mankind to-day has a double heritage. The one comes to us without any effort on our part, as do the spider's peculiar characteristics or those of birds, or of any of our fellow mammals, come to them. It is secure and tends to remain the same for thousands of years. Civilization, on the other hand, is precarious; it must be assimilated anew by each one of us for himself in such a degree as circumstances permit. It can increase indefinitely but it may also fall off tremendously, as the history of man amply testifies. It is a legacy that can be lost as well as kept and increased.

To illustrate: it may be that before human beings had acquired any of this loseable thing, civilization, they would pick up a stick to strike an assailant or hurl a stone at him. They might have found themselves riding astride floating tree trunks to cross a stream. Certain persons would occur, let us say, in each generation who would do all these things without ever having seen them done. These acts would be classed in man's animal heritage. But should we find traces of men who chipped a flint nodule into a hatchet head, and hollowed out their log with such a hatchet, or with fire, we should have to class these acts among the arts of civilization since they presuppose so much accumulated experience and ingenuity that they could not be inborn. The art of making a rude boat might consequently be wholly lost, as surely many inventions must have lapsed, if a single generation passed without constructing one.

It seems now an imperative fact that all civilization—the total social and traditional heritage, would fall away immediately and completely should a thoroughgoing forgetfulness, an overwhelming amnesia and profound oblivion overtake humanity. Only their natural equipment would be left. As Graham Wallas suggests, those least civilized would have a possible chance of surviving. It is only uncivilized man that might go on indefinitely. We are all by nature wild animals *plus*; and our taming weakens us for the ancient struggle in the forest, naked and bare-handed.

PECULIAR ITEMS OF MAN'S BODILY FORM

At this juncture the question arises, what was there peculiar in man's physical make-up that enabled him to initiate civilization and build up a mind which he could use to increase his resources so far beyond that of any other animal? Before proceeding we should recollect that the ways of all living creatures are manifold and astonishing. Even a single-celled organism can marvellously adjust itself to altered conditions. It seems to learn by experience, it appears to have a sort of memory, it is modified by happenings which interrupt its comfortable routine. It is ingenious in defending itself, in seeking food and reproducing. It is, in short, purposive in its conduct. The tiger and the frog are able to adjust themselves to very different modes of life, and so are the orioles and cacti. Before man began to accumulate civilization we are forced to assume that he too made terms with the

daily need of adjustment which faced him, otherwise we should not be here to write the tale. These are the salient essentials of *Life*, and man is a part of what Julian Huxley calls "the stream of life." All these possibilities lay behind the development of man's intelligence. They are the hinterland from which civilization emerged and to which it ever tends to retreat.

In order to begin and carry on the accumulation of civilization, man had of necessity to be so constructed physically that he could *perceive* more clearly than his predecessors, make more accurate distinctions and so remember and imagine better; for all these are essential to talking and thinking. The awareness of animals is of a low, vague type, and so must pristine man's have been. The one-celled animals behave in a purposive way, but they have no eyes or ears or noses. They must live in silence and darkness like a human blind, deaf mute. They will nevertheless take in certain food and reject other things. They perceive and act without, so far as we can see, being conscious of their actions. They make the necessary decisions without deciding in a human sense. They have no nervous system, but, as has lately been discovered, the promise of one. The creatures most like ourselves have eyes, ears and noses, and evidently see, hear and smell; and they have an elaborate nervous system. Of these resources they make constant use. But compared with man they are ill-qualified to make careful distinctions and discriminations and remember clearly. They take note of far fewer factors in their situation. They must act somewhat as our digestive system does. It is a sort of animal within us which performs wondrous feats when given food. It works purposively, as does our heart and blood circulation. We can become *conscious* of these unconscious achievements when we choke, because the switch is not thrown promptly enough to prevent a morsel from going down our windpipe instead of taking the route to the stomach. Palpitation of the heart is a conscious suggestion of the faithful pump, which rarely reminds us of its constant attention to business. Let it neglect two or three beats and we are dead.

The essentials of man's physical equipment for initiating and piling up civilization have been dwelt upon by many writers. He has sensitive hands, and (after he got securely on his hind legs) he could use them far more freely than if he had to employ them as auxiliary feet. His thumb can be readily placed against any one of his fingers. There is no such expert feeler and handler as he to be found among his kindred. He could learn much of shape and form, of softness and hardness, of weight, texture, heat and cold, toughness, rigidity and flexibility, which could be but vaguely sensed with hoof or paw. Had he had ears that he could turn about like a jack-rabbit, and a prehensile tail, he might have been able to learn faster. And all these things were the beginning of knowledge. He could not only strike but hurl. His eyes were so placed that he was always looking through a stereoscope, so to speak, and seeing things in the round. His vocal organs promised a great range of delicate discrimination in the sounds he made. Then he was a helpless dependent for many years on his elders so that their acquired ways could become his.

Lastly there is man's brain with its complex cerebral cortex and its association paths, which develop astonishingly as a child grows up. The cortex is the prime correlator of impressions, and is modified through individual experience in a higher degree than any other part of the nervous system. Its functioning is still very mysterious, but no one doubts its essential rôle in the process of human learning and the increase of intelligence. Its operations are not, however, autonomous but closely associated with the experiences of the whole human organism and dependent on those singular capacities of mankind already mentioned.

So it becomes apparent that after hundreds of millions of years during which nature's experiments have been going on in physical structure and function, which have enabled creatures of the most diverse types to meet the absolute requisites of life—growing up and reproducing their species—a kind of animal finally appeared on the earth so constructed that he could become civilized. Man's biological make-up represents a unique combination of physical characteristics. Most of these, as we have seen, occur in other mammals. Even those which seem peculiar to him would not

serve, however, as a foundation for the development of civilization except in a highly complex union. Cows might have a human cerebral cortex, foxes apposable thumbs, birds stereoscopic eyes, dogs vocal organs similar to ours, and yet civilization would be far beyond their reach. Man can teach all of them tricks. They themselves can learn something as their life goes on. Chimpanzees may under favourable circumstances, as Köhler has shown, make very simple, human-like inferences; but none of them could initiate and perpetuate the arts and sciences as a heritage of their species.

PROGRESS AND CONSERVATISM

Such then was man's original equipment for getting civilized. He had, obviously, no means of foreseeing the enterprise in which he was engaged. His evolution as a civilized being was no more premeditated than his rise from earlier simian ancestors. There seems to be sufficient evidence that for hundreds of thousands of years changes in his mode of life were so gradual and rare as to pass unperceived. Each generation accepted the conditions in which it was reared without thought of betterment. Our modern hope of "progress"—an indefinite increase of human knowledge and its application to the improvement of man's estate—was practically unknown even to the Greeks and Romans. From the 13th century onward a few writers dwelt upon the promise of the future, but they were outclamoured by those convinced that human woes were attributable to a departure from ancient standards. The Humanists strove to re-establish the wisdom of the classical writers, and the Protestants sought to revive the beliefs and practices of the early Christians. Only three centuries ago did Bacon unroll a programme of aggressive search for the hitherto unknown, which had any very wide influence. In the 18th century the conception of reform and progress found illustrious spokesmen, and their anticipations of coming changes in the economy of human life were destined, as it proved, to be far outrun by the events of the 19th and early 20th centuries.

We can, however, still note on all hands illustrations of man's confidence in routine sanctified by ancient authorities; his suspicion of innovation in wide realms of belief and practice. This dogged obstinacy in clinging to his habits, and his general suspicion of the unfamiliar, are exactly what might have been anticipated when we consider his animal origin. This trait has served to slow down the process of change, but at the same time has greatly increased the security and permanence of each achievement. Here we find a possible explanation of the great rôle that the veil of sacredness has played in man's development. He has cast it over beliefs and practices and so hid them from pert scrutiny and criticism. The number of those who can tolerate somewhat critical thinking here and there, has, nevertheless, greatly increased of late, but they are still few indeed. What we call to-day a conservative or reactionary mood must have been characteristic of mankind from the beginning. It corresponds to animal inclinations.

Among animal proclivities there is, however, from the one-celled organisms upward, a life-saving tendency to make random movements, extensions and contractions, to hasten hither and thither, in the pursuit of food and mates. This restlessness and groping are among man's legacies also. They offset his routine and static habits, and lie behind and back of the inventions and discoveries he has made. There is, too, especially obvious among the higher animals, something auguring what in man becomes curiosity. The danger of attack made preliminary scouting a valuable asset in survival. So men were by nature wont to pry and try and fumble, long before they scientifically analysed and experimented.

There can be no doubt that hundreds of thousands of years were required for man to reach even the lowest degree of culture to be found among the simplest tribes to-day. The discovery of fossil skulls, teeth and bones at different geological levels shows that more or less ape-like men have been on earth for from half a million to a million years. Several species, such as the Java man, the Heidelberg man and the much later Neanderthal race are now extinct. The only vestiges of their handiwork consist in chipped flint tools, becoming better made and more varied

as time went on. There is no way of telling what other arts, beliefs and practices were associated with a particular assortment of flint utensils. Sollas, in his *Ancient Hunters*, has sought to draw ingenious analogies between these prehistoric weapons and the civilizations of the Tasmanians, Australians, Eskimos, etc.

The so-called Cro-Magnon race had finely developed skulls quite as good as those of to-day. To them are ascribed the remarkable paintings and drawings found in caves of southern France and northern Spain. They are believed to be from 25 to 30 thousand years old. Halving this period we come upon traces of ground and polished stone tools, coincident with the relinquishment of hunting as man's exclusive pursuit and a settling down to sow and reap, spin and weave. Halving it again, we get news of the use of copper, the precursor of the metals on which our civilization largely rests. This can but be a rough chronology subject to much revision as time goes on and the earth is more thoroughly searched for evidences of man's past.

To get the matter clearly before one, let us imagine, as the writer has suggested elsewhere, that 500,000 years of developing culture were compressed into 50 years. On this scale mankind would have required 49 years to learn enough to desert here and there his inveterate hunting habits and settle down in villages. Half through the fiftieth year writing was discovered and practised within a very limited area, thus supplying one of the chief means for perpetuating and spreading culture. The achievements of the Greeks would be but three months back, the prevailing of Christianity, two; the printing press would be a fortnight old and man would have been using steam for hardly a week. The peculiar conditions under which we live did not come about until Dec. 31 of the fiftieth year.

There is a school of anthropologists, the diffusionists, who would derive all the higher types of civilization—writing, metalurgy, the construction of imposing stone buildings—from a single region, Egypt. They have collected much evidence to show that through the commerce of the Phoenicians, Egyptian inventions spread eastward into India, China and Japan, then across the Pacific to form the basis of Maya culture in Central America. The merits of the "diffusionist" arguments cannot be considered here. G. Elliot Smith, one of the best known advocates of this theory, dwells on the common lack of inventiveness and the reluctance of mankind to adopt new ideas, his tenacious hold on old ones and "his thick armour of obstinacy." "To obtain recognition of even the most trivial of innovations it is the common experience of almost every pioneer in art, science or invention to have to fight against a solid wall of cultivated prejudice and inherent stupidity."

All anthropologists are well aware of this hostility to change, which we may regard, as shown above, as a natural trait of mankind. They also admit the wide dissemination of inventions through commerce and conquest. Nevertheless many maintain that the same or similar discovery has been made independently in different parts of the earth, as the result of similar needs and conditions. When we have examined the exigencies of successful inventions in the following section we shall see that however commonplace they are now, with the accumulation of the past to build upon and modern facilities to work with, they were beyond measure difficult at the start when mankind still led the life of an animal. When once made and adopted by some tribe it is far easier to think of them as being introduced to other peoples than to assume that their presence represents an independent discovery.

Civilization depends upon the discoveries and inventions man has been able to make, together with the incalculable effects these have had upon his daily conduct, thoughts and feelings. As knowledge and ingenuity increased he departed further and further from his original wild animal life. The manner in which he began to learn is a matter of conjecture, since the manufacture of tools and weapons, the invention of language and artificial ways of producing fire, far antedate any written accounts of advances in man's education. The same may be said of the much more recent spinning, weaving and farming. As we have seen, it required hundreds of thousands of years to reach the degree of civilization represented by these achievements. Their

importance, however, cannot be overestimated, since they formed the absolutely essential basis of all later developments. We may feel a certain pride in contemporary inventions, but let us remember that we owe to savage hunters and illiterate neolithic farmers the accumulation of knowledge and skill without which none of our modern experimentation would be possible. Where would we be without fire, speech, clothes and bread!

Since invention, discovery and the increase of knowledge are the stuff of which civilization is made, it is pertinent to our theme to consider how they occur. There is plenty of evidence available in the reports which discoverers now make of the manner in which they reach their conclusions. There is also evidence of how their results are received and acted upon by others. All explorers must be exceptionally curious and at the same time patient gropers. The curiosity observable in most children tends to die away, but survives in one form or another in rare instances through life. These exceptional persons possess a drive alien to their fellows. They may be the handyman of a village or a member of a highly endowed research staff. They avail themselves of what has already been found out; the village mechanical genius does not have to invent a monkey-wrench or bit of insulating tape, nor does the biologist need to know much about the optical principles of his lenses, much less invent or manufacture them. The geologist before he makes any discoveries is familiar with hundreds of treatises on his subject. It would be generally conceded by investigators that their discoveries are seemingly accidental. They do not know what they are going to find, and quite commonly find what they were not looking for, even as Saul, chasing lost asses, came upon a kingdom. All this applies to every kind of increase of knowledge, whether it have to do with the operations of so-called Nature or with novel suggestions in the realms of philosophy or art. All are the result of curiosity, patient examination and thought. At best they are no more than foot-notes and glosses added to existing human knowledge. This is now so varied and voluminous that no single person can compass it except in this detail and that. Should he attempt to do so, all chance of adding to it would be excluded.

But an invention or discovery or the rectification of an ancient error, does not become a part of civilization until it has been accepted by the tribe and been added to its habits of action and thought. Plenty of shocking tales could be recalled of professional and popular opposition to innovations on grounds which now seem grotesque. We owe discoveries to individual men and women, but new information and skill can only be propagated and disseminated in a favourable culture medium. Many instances could be cited of promising knowledge which has so far failed to get a footing in civilization.

The influence of particular discoveries and mechanical devices is by no means confined to their more immediate and obvious applications. It is impossible to foresee what wide-ranging effects they may ultimately exert on human life. Fire will cook a meal, harden an earthen bowl, keep a group of naked savages warm, frighten off prowling animals, soften or melt metals; it may also consume sacrifices to the gods, or form the central interest of a stately temple and be replenished by an order of vestal virgins. It may play its part in the symbolism of the theologian and the poet. The Indians of the North American plains were deeply affected by the introduction of the horse, and African tribes by fire-arms and whisky. The motor car and telephone altered social relations. The perfecting of the steam engine revolutionized the transport of men and their wares; it promoted city life; further, it caused Marx to write a big book which became the gospel of a momentous social upheaval, which threatened the peace of mind of all nations.

The invention of clothes—quite material things, whether of linen, wool, silk or cotton—not only created great industries but enabled men by changing their hide artificially to establish social distinctions akin to biological genera and species. Through clothes entered in prudery and the pious horror of bare bodies which has wrought consternation and disaster among the dark-skinned folk. After the World War women's skirts were gradually shortened. The warmth of houses and vehicles permitted this. One of the conventional distinctions between girls and women

was thus obliterated. The unveiling of women's faces in Mohammedan countries, the breaking down of *purdah* in India—all these material changes imply modifications of woman's life and of the attitude of the sexes to one another. They forecast further important changes in traditional civilization.

In view of these facts, and indefinitely more that each one can easily add for himself, it would seem that what are esteemed the "nobler" aspirations and creations of mankind, whether in art and literature or the pursuit of truth, are all not only dependent upon "material" inventions but so strangely interwoven with them and their effects that it is no easy thing to separate the higher and the lower, except in imagination. What is sometimes called "the higher life of man" arises from his more humble and practical knowledge and skill; accordingly the old distinction between the material and spiritual seems to be greatly attenuated as they are both seen to merge into the newer conception of civilization as a whole. This will become even more apparent when we come to deal with words.

RÔLE OF CHILDHOOD

One of the essential conditions for the perpetuation of civilization is the long period of dependence through which the human child must pass before it gains sufficient bodily strength and intelligence to achieve merely animal self-sufficiency and make its own way. Without the constant and prolonged succour of adults it would speedily perish. This means that the extended period of helpless susceptibility to his surroundings makes it possible vastly to modify a child's original disposition. A mouse is sexually mature in six weeks and fully grown in three months. Calves and colts walk about shortly after birth. The gorilla, on the other hand, has a prolonged childhood, requires ten or twelve years before it is able to breed, and goes on growing, like man, for a few years after. He lacks, however, in spite of his prolonged childhood, the other essential traits which have enabled mankind to initiate, increase and transmit civilization.

We are all born uncivilized and would remain so through life were we not immersed in civilization. There is a long time in which we may, according to the place where we are born, be moulded into a well authenticated Papuan, Chinaman, or Parisian. We cannot choose whether we shall find ourselves talking like a Fotentot, a Russian or a German. And we learn to do in all things as those do among whom we are brought up. We cannot but accept their respective customs, scruples, and ideas, for all these are imposed upon us before we have any choice or discretion. We must perforce follow the ways of our elders, who themselves were once children and gained their civilization before any discrimination or comparison with other than the prevailing habits as possible. This is the inexorable rule, and it accounts for many of the striking characteristics of civilization.

If the assimilation of culture is closely associated with the dependence and adaptability of childhood there need be no great surprise that accumulating evidence seems to indicate that when bodily maturity is once reached, the increase of knowledge and intelligence slackens or even almost ceases in many cases. By 13 or 14 the child has acquired an overwhelming part of the knowledge, impressions, cautions and general estimates of his fellow creatures and the world in which he lives, which he continues to labour with slight modifications during his lifetime. When as a result of the participation of the United States in the World War it became necessary to test the competence of a great number of young men an unforeseen contribution was made to our insight into civilization. Of the 1,700,000 examined, 45% did not show themselves (to quote an eminent authority, Dr. Henry H. Goddard) much above the 12-year-old limit. Those tested, it must be remembered, did not include idiots or "morons," but the average of youths accepted by their fellows as normal. While tests may be as yet inadequate they but confirm the observable fact that the inculcation of culture is associated with bodily growth and especially with the strange changes in the cells of the brain and their intercommunications. These developments are tremendous from infancy to maturity in so-called normal cases. Only in exceptional instances does mind-building continue steadily after childhood and adolescence. We have had time before 13

to take over the standardized sentiments of our elders, to learn all that they know, to accept their views of religion, politics, manners, general proprieties and respectabilities. The common run of mankind can, however, be taught tricks as time goes on and acquire special expertness. But a great part of our childish conceptions retain a permanent hold on us. There is usually little encouragement to alter them. We leave most of them unrevised, though we have to make adjustments as the years elapse. Human beings seem on the whole easily subdued to routine and the routine is established, as it would seem, by the time we are grown up. That the *ability* to learn, however, falls off very slowly after adulthood has been recently shown by E. L. Thorndike.

The experts in advertising, the publishers of "tabloid" newspapers and the contrivers of moving picture films seem to conform to the supposition that what appeals to a 12- or 13-year-old child is admirably adapted to the intelligence and tastes of the multitude. This means that the overwhelming majority of men and women assimilate in childhood the common and familiar forms of civilization or culture in the midst of which they find themselves, but hardly outrun them as life goes on. Perhaps one in a hundred may allow his opinions to be altered by assiduous reading, or take pains to cultivate his insight into art and literature and scientific discoveries. But all these and other contributions to one's personal civilization are outside the range of the human animal in general. Indeed the mere upkeep of our present complicated culture must depend upon a very trifling percentage of the population. Were a few thousand carefully selected infants in the various progressive countries of the world to be strangled at birth not only would advances in industry, arts and letters cease but a decline would set in owing to the lack of those to make the essential readjustments in our industries and their financing; to keep up laboratories and books at their present standards. Accordingly the great majority of human beings can barely maintain at best the civilization in which they were reared. Even the innovators considered above, are unable to escape from the toils in which they were so easily enmeshed and which they regard not as entanglements and restraints but as comforts and assurances. It would be faithless and disloyal to regard them otherwise. Only peculiar temperaments under highly favourable conditions question what they have been taught. They can do this only on a most modest scale as a result of continued curiosity and study. A physicist may reach a new theory of the constitution of atoms and yet cling stolidly to the notions of religion he had acquired at ten years of age; he may even engage in subtle philosophical speculation and remain a hot defender of the *mores* of the most commonplace persons 50 years ago.

If these points be well taken the whole contrast between Society and the individual which has been played up in various rather futile ways takes on a new aspect. From the standpoint of civilization each individual owes his entire equipment as a civilized being to others. Biologically even, he is vastly modified by his domestication, in habits, impulses and moods. The so-called "instinct of the herd," which Trotter has made famous, tends to become an unnecessary hypothesis. For every child is made by others in their own image. How gregarious mankind was before the onset of civilization it is impossible to say; but the prolonged infantile weakness implied multiform dependence upon others. Of course there is really no such thing as Society in the sense of some powerful and precious personality for whose welfare the so-called individual is invited to make appropriate sacrifices of personal preferences. What we have to do is to make terms with the notions of "the good" and "the bad" which those profess with whom we are thrown. These rules of conduct and sentiment constitute Society. They have their heavy sanctions if violated or impeached—disgrace, persecution, imprisonment and even death. The methods of eluding Society constitute a highly interesting chapter in the history of civilization. It is not difficult for the shrewd, and seems greatly to enrich life for certain temperaments, whether one be a burglar, a story-teller, or a philosopher. Wholesale deceit has established the reputation and fame of many a hero from Jacob and Ulysses to those in high places to-day. Boldness of thought is less likely as yet to arouse primitive enthusiasm.

WORDS VIEWED AS DEEDS

One of the most stupendous elements in civilization has hitherto been only casually mentioned—words. Without language civilization could hardly even have begun and certainly could never have attained its higher forms. Speech underlies thinking and conscious planning and research. It does more. It creates a world of ideas which interpenetrates and seems to transcend that of the facts of human experience. What pass for facts are indeed so moulded by our notions of them that recent philosophers are less and less confident in their efforts to separate the functioning of ideas from that of facts. Much has been discovered of late which serves to revolutionize the older theories of language and thinking, and to eliminate some of the age-long quandaries in which philosophers have found themselves involved. These new views can be only briefly suggested here.

The Fourth Gospel opens, "In the beginning was the Word; . . . All things were made by it; . . . In it was life; and the life was the light of men." Goethe declared that in the beginning was the deed. The most recent writers who deal with speech would seek to shed new light on civilization by recognizing that words have always been deeds. They have always been regarded as wonder-working acts; they create things which without them could never exist; they are the chief light of man—and his darkness as well.

Making noises is a conspicuous animal trait. Katydid, frogs, whippoorwills, dogs, and many other creatures exhibit a tireless patience in this matter. Man, too, is a great chatterer. His fellow men may be bored by his talk, but they are likely to be scared by his silence. It is portentous and bodes no good. To keep still is an unfriendly act. So, as Malinowski has pointed out, one of the many functions of utterances has been reassurance and the expression of companionship. The cries of animals as related to their needs and behaviour are only just beginning to be carefully studied. Whitman and Craig have discovered a marvelous correlation between the ejaculations of pigeons and their ways of life. Köhler, Yerkes and others are attending to our nearer relatives. But all that needs be noted here is that human language must have emerged from the spontaneous sounds made by pre-man.

Only when men began to make pictures of events and gestures, and painfully developed writing from the pictures, have we the least actual evidence of language. The Egyptian inscriptions illustrate picture writing and its later and most ingenious metamorphosis into sound symbols—an alphabet. This happened five or six thousand years ago. But it is clear from the Egyptian language that its surprising complexity and sophistication imply an antecedent development of incalculable length, to judge from the slowness of man's material inventions.

While the beginnings of language are hidden from us by the lapse of hundreds of thousands of unrecorded years, there are several new ways of coming to a far better understanding of them than hitherto. There are historical and contemporaneous sources of information which have been exploited of late and serve to revolutionize the older views. For example, the so-called primitive languages (until recently, never reduced to writing), afford a sufficient proof that words are fundamentally acts, closely related to man's other conduct. Then, watching the way that babies—the Latins aptly called them *infantes*, or speechless creatures—learn to talk, greatly re-enforces and corroborates the evidence derived from the study of "illiterate" tribes. Lastly, anyone who has learned the trick, can substantiate the same thing if he tests the babble always going on around him.

We have already noted one way in which speech is a mode of action, a friendly gesture, not an expression of thought or conveyance of ideas as philosophers have taught us. "How do you do?" is not a question to be answered under usual circumstances. One concurs in the obvious statement, which conveys no fresh information, "Fine day, sir." These are just tail-waggings, like taking off one's hat, bowing, smiling and hand-shaking. We can, however, do far more with language; we at times can strike with a word more safely and more effectively than with our fist; by words we can cower, and dodge, and elude danger. Those in high-

est standing in all communities make a living by words, unwritten and written. Whole professions confine their activities to words,—clergymen, teachers (of the older type), lawyers, politicians; brokers deal in alternately saying "buy" or "sell." Doubtless other things lie behind this trafficking, but words are effective acts, or so intimately intertwined with them, that it is impossible to say where one sets in and the other ends. Pure talk and written words seem often to do the business without the intervention of so-called things. The magic operations and achievements of words can be observed everywhere and in all ages. Jacob and Esau struggled bitterly to win a blessing from their blind old father. His words were momentous. They might cause unborn generations to bow down before his son's offspring or doom him and his children to perpetual slavery.

As a clergyman of the 18th century remarked, "Words have a certain bewitchery or fascination which makes them operate with a force beyond what we can naturally give account of." Joy and infinite woe follow in their train; from which our wordless ancestors must have been spared. The main emotional structure of civilization—so poignant and so unique an element in human life—is largely reared on words. They serve to establish new orders of sensitiveness and excitability. Words increase the clarity of our memory to a tremendous degree and at the same time they vivify imagination, which could exist on no considerable scale without them. With these word-created adjuncts we can elaborate our hopes, fears, scruples, self-congratulations, jealousies, remorses and aspirations far beyond anything that seems justified to the onlooker; we can project them backward into the past and forward into the future. Words can rear more glorious palaces and dig deeper, darker dungeons than any made with hands.

TALKING AND THINKING

What has so far been said of the recent views of language helps to explain the newer interpretation of the old terms mind and reason. These seem to be processes, as we have seen, rather than agents. They are ways of doing things rather than things themselves. John Dewey calls his admirable little book on mind, *How We Think*. When older philosophers began to think about thinking, and how by thinking we reached truth, they commonly found themselves writing very long books, very hard to read; and they called their great theme epistemology or the theory of cognition. The effective thinking which has built up civilization has not, however, relied upon their treatises; nor has it been influenced by them. Two or three considerations only can be touched upon here which impress recent students in investigating thinking.

Thinking and words go together. For thinking, to be clear, has to rely upon names and their various associations with one another. For instance, grocer's bill, cheque-book, fountain-pen, envelope, stamp, letter-box are names put together in a particular sequence. Of late there has been a good deal of discussion as to whether thinking was not always talking quite noiselessly to ourselves. A child will first utter sounds at random, then begin to find that the sounds he makes bring things; then he gets to naming with vast enthusiasm; then he prattles too freely and inopportunistically to please his elders; then he may merely move his lips—as many childish people continue to do—and finally hold his tongue. It can be shown, however, by appropriate tests that this suppressed talking is accompanied by muscular adjustments of the vocal organs which indicate a silent execution of the words and sentences. We can say openly "That's too bad," or mutter it, or adjust our organs so as to say it if we wished. This suppressed talking seems to be thinking. That all thinking is merely talking to ourselves many will doubt or deny. While some minor reservations are justifiable there is an overwhelming mass of evidence, derived for instance from the study of deaf mutes, that fortifies the contention stated above—no words, no thinking.

But thinking can easily be seen to be of several varieties. There is the meandering succession of recollections, vague apprehensions, hopes, preferences, disappointments and animosities which has come to be called *reverie*. It underlies other and more exacting forms of thinking. It is found on inspection to consist of recollections, anticipations, excuses for past or contemplated con-

duct, reflections on the unfairness of our fellow creatures and of the world in general; or assurances that all is well and must in the nature of things remain so. Ordinary daily planning is an essential form of thought—making homely decisions and adjustments. Underneath, we can perceive the reverie flowing as a sort of undercurrent—for thinking is very complicated.

We occasionally turn our thinking to trying to find out something that we do not yet know. This may be the result of mere personal suspicions and vulgar curiosity, or of an honest desire to improve a defective social situation, or learn more of light waves, Chinese paintings, psychoneuroses or investments. In dealing with the workings of the physical universe a special kind of thinking, the mathematical, has produced results that tend to safeguard the investigator from the usual prejudices which beset us in all thinking. It is a peculiar, highly refined language, or way of talking about things, by employing the vocabulary of sines and cosines, logarithms, constants, variables, roots, powers, etc. It has proved to be a wonderfully fruitful way of talking about light, for instance, and the nature of "matter" and "force" and in dealing with engineering problems. Few are addicted to this type or any other variety of scientific thinking. Most practical inventions seem to proceed from our power to experiment by thinking; to fumble and stumble mentally, and sometimes succeed. This mental trying-out is a kind of trial and error. It cannot proceed long without various external acts to check up the guesses and inferences produced by meditation.

One of the most novel and promising methods of learning more about all kinds of thinking is abnormal psychology. Illusional and obsessive thinking which fill the mad-houses appear to be only the exaggerations of the thinking of those at large. The psychiatrists hold out hopes of discovering through their special knowledge, and a study of infants and children, ways of eliminating or reducing some of the vices of civilization as it has hitherto developed. To them civilization is in many of its manifestations a species of mild madness; these can only be eliminated by a great change in the way children are brought up, so as to obviate the maladjustments and distress incident to a rapidly altering cultural environment.

Men and women think not only when they are awake but when they are asleep. Their sleeping thoughts and visions and experiences we have learned to set off sharply—far too sharply as it would appear—from waking thought. Primitive man did not do this. He did not deem his dreams mere illusions, comical or distressing, to be banished when he opened his eyes. They were not negligible to him but quite as real and instructive for conduct as what he saw in the day-time. Indeed they had a weight and authority superior to the pronouncements of daily experience; and they served vastly to widen it. What civilization would have been without the manifold influences of dreams it is quite impossible to guess. Had man been dreamless would he have had his religions, his symbolism and his allegories, his poetry and much of his art? This much at least is assured that the beliefs and practices of primitive peoples are in many cases directly attributable to their dreams. Later beliefs and practices of more elaborately civilized peoples can usually be traced back to primitive ideas, which seem to be the soil from which they sprang. So we have to conclude that dreams are one of the most remarkable factors that have entered into the fabrication of civilization as we know it to-day.

When asleep we find ourselves visiting distant places; for instance when walking the streets of Paris we suddenly wake in New York. How could early men escape the conviction that they had a second self which could wander forth from the body, leaving it behind in the hut, while the "spirit" led for a time an emancipated and adventurous existence freed from the slow and lumpish flesh? Then in dreams the dead appear to us in full life and activity. They may admonish or fortify us; rebuke our departure from the old ways, or fill us with assurance of success. The North American Indians shared the confidence of the ancient Hebrews and Romans in dreams. In India and China the veneration of ancestors forms a highly practical obstacle to the introduction of Western institutions. So have we here, without the

possibility of much question as to the main issues, a fair explanation of the original belief in the spirit or soul and its survival of death. We have much more. We have the dawn of the gods and the demi-gods, and the whole foundation of beliefs about supernatural beings and their converse with men; their anger and the possibility of their propitiation by sacrifice.

LOOKING FORWARD

In the preceding sections of this article certain important considerations are enumerated which escaped until recently the attention of students of mankind. They are clear enough when once pointed out. But it has always been a tragic trait of civilization that the obvious has been difficult to perceive, for it is too familiar to catch our attention. It requires a peculiar penetration to discover what in all discussions we are unconsciously taking for granted. And what we are most prone to take for granted are unrevised childish impressions.

There is much complaint of the childishness of mankind, which has become more conspicuous with the democratic assumption that everyone should have his say. Langdon-Davies' *New Age of Faith*, and E. C. Ayres' *Science the False Messiah*, to cite two examples, dwell with some petulance and bitterness on the easy gullibility and obstinate ignorance of humanity. They assume standards of intelligence which obviously do not prevail, as one reads popular newspapers, sermons and political speeches. They are disappointed, but have no reason to be surprised. Why should an ex-animal not have made grotesque mistakes as he floundered about with words and besetting mysteries and hardened orthodoxies? Then, as we have seen, civilization is mainly acquired in childhood and perforce ever haunted with infantile longings and misapprehensions. When there is an issue between his dreams and visions and his waking experiences why should man not prefer the former? As a matter of fact those reputed as great and deep thinkers have dealt mainly, until very recently, with imaginary beings, with events that never happened; with empty concepts, allegories and symbols and false analogies. John Dewey has in his *Reconstruction in Philosophy* deduced philosophy and ethics from savage antecedents and shown how these have interpenetrated later speculations. The hardly to be overcome prejudice which attributes to mind and body separate existence and regards them of diverse substance is the easily explained and inevitable mistake of a savage. The will, the unconscious, the moral sense, regarded as agents, belong to the category of primitive animistic conceptions. Even causation as it used to be conceived is but an expression of the naïve urge to blame or praise some particular person or thing for this or that event. We are now learning to think in terms of situations. For example when Edward Carpenter wrote many years ago on *Civilization, its Cause and Cure*, he yielded to a venerable usage. It has become apparent enough that civilization has had no one cause but is the result of a situation of cosmic complexity. There can be no one cure for its recognized defects. A recent Italian writer, Pareto, has filled two large volumes with instances of the misapprehensions upon which current sociological treatises are based.

As humanity, or at least their leaders, become more fully aware of the nature and origin of civilization and the manner in which it has hitherto developed they will discover firmer foundations on which to build, more efficient ways of eradicating the inevitable and congenial errors of the race, and of stimulating patient and fruitful reconstruction and reform. So far mankind has stumbled along, enslaved by its past rather than liberated by it for further advances. The reasons for this are beginning to become more apparent than ever before and might as time goes on be made the basis of a type of education, especially in man's early years, which would greatly forward and direct the progress of civilization rather than retard its development. (J. H. ROB.)

CIVIL LAW, a phrase which, with its Latin equivalent, *ius civile*, has been used in a great variety of meanings. *Ius civile* was sometimes used to distinguish that portion of the Roman law which was the proper or ancient law of the city or state of Rome from the *ius gentium*, or the law common to all the nations comprising the Roman world, which was incorporated with the former

through the agency of the praetorian edicts. This historical distinction remained as a principle of division in the body of the Roman law. The municipal or private law of a state is sometimes described as civil law in distinction from public or international law. Again, the municipal law of a state may be divided into civil law and criminal law. The phrase, however, is applied *par excellence* to the system of law created by the genius of the Roman people, and handed down by them to the nations of the modern world (see ROMAN LAW). The civil law in this sense would be distinguished from the local or national law of modern states. It is further to be distinguished from that adaptation of its principles to ecclesiastical purposes which is known as the canon law (*q.v.*). In countries which have codified their law the civil code contains the legislation which governs the civil relation of the citizens *inter se*, but excluding subjects dealt with in special codes, such as commerce, procedure and crime. It therefore includes citizenship, marriage, divorce, contract, sale, partition, exchange, mortgage, usufruct, servitudes, succession, wrongs and so on. (See CODE.)

CIVIL LIBERTY, as known in western Europe, consists of (1) freedom of the citizen in regard to personal action and property—not merely from State control but also from private oppression by individuals or corporations from which the State should protect him, (2) freedom in regard to religious worship and the expression of opinion and (3) participation in the government of the community in which he lives. Civil liberty is limited by the necessities of public safety, which fluctuate, *e.g.*, between the conditions of peace and war; but it should not be at the mercy of any governing clique which wants to carry out experiments in *e.g.*, what it chooses to call social welfare. Conscription may be necessary in wartime; but compulsion to wear digitated socks in peace time is a very different matter.

Origin of Idea.—The idea of civil liberty as a right was unknown to the ancient world and is still unknown both in the Near East or the Far East. In China and Japan the individual is insignificant except as the member of a family or village community. In modern Italy and Russia, and to some extent in Spain, the idea of civil liberty is frankly scouted and suppressed. The first germs of it appeared in the Stoic philosophy and these were developed by Christianity which inspired revolt against the family as well as the State. Individuality found further support in feudalism, for the feudal tie of allegiance at least recognized the rights of the small property owner and the voluntary character of his service. This was particularly the case in England, where the more efficient centralization of government severely controlled private war and developed the proprietary instinct in an atmosphere of peace; for liberty is essentially bound up with property. The Black Death converted many serfs into small property owners.

Mediaeval Europe also developed civil liberty by the differentiation of Church and State as opposed to the identification of priest and king in the primitive and ancient worlds. The clash of Church and State, as of hammer and anvil, produced sparks which kindled unexpected tinder in the region of liberty. Even in ancient Athens no citizen was allowed any right of private worship or approach to the gods of the community; but the mediaeval Catholic had his own little shrines and saints. In England, too, the turbulent islanders kicked against papal control and would not put up with the inquisition.

The Renaissance and the Reformation.—The Renaissance developed even further the idea of individual liberty tempered by despotism and the growth of national monarchy. The utmost freedom in conduct and speculation prevailed under a system of political repression. The citizen could do much what he liked provided he left politics alone. This kind of liberty prevailed all over Europe in the 18th century and in countries like Russia and Germany up to the time of the World War.

The Reformation was not based on any avowed principle of individuality and nearly all the compromises of the 16th century were repudiated in the 17th century; but it put in motion most of the events which resulted in modern toleration. Thus in France the Edict of Nantes, involving the toleration of Protestant by Catholic, was achieved in 1598, but revoked in 1685. In Germany

the principle of *cujus regio eius religio* was formulated in the Peace of Augsburg in 1555, though not finally established till the end of the Thirty Years' War. The Elizabethan settlement and Cromwellian eclecticism crystallized into the Toleration Act of 1689, under which more than one sect was permitted civic existence. Quakers and Catholics, however, were not in a very happy position until the beginning of the 19th century, and atheists were more or less outlawed until the last decade of it, though on the continent the French Revolution accelerated the toleration of free thought. In the 20th century the persecution of Christianity has begun; the expulsion of the monastic orders from France has been followed by the anti-Christian extravagances of the Russian Soviet.

Power of Land Owners.—Direct participation in government has always been fairly impracticable except in small communities *e.g.*, the ancient Greek or mediaeval Italian City State or the Swiss canton or West Indian colony of modern times. The power of insurrection has never been so easy a remedy against despotism for a servile proletariat as it is for a population of small burgesses or yeomen; still in mediaeval Europe the tyranny of the monarch or of the feudal nobility could be and was checked by risings under leaders like Wat Tyler or Etienne Marcel, of a more virile population than the spoon-fed town dwellers of the 20th century. In England the monarchy became impoverished owing to various causes after the Reformation and the power of the great landowning oligarchy became established in 1688 and remained until it made way for the new industrial oligarchy of the Victorian era and finally for the plutocracy of the present day. In Austria, Germany and Russia monarchy survived until the crash of 1914. In France and Scandinavian countries something more like democracy was achieved with results fatal to liberty except in France, which has always preserved the traditions of European civilization.

It may safely be said that ultimate sovereignty reposes on the ownership and cultivation of the soil, for the soil cannot be cultivated except by skilled individual labour as the ancient Roman and modern Russian discovered. Thus in England political power rested with the big landowners from Magna Carta in 1215 down to the Great Rebellion and the Revolution of 1688. Modern France has been ruled by the peasant proprietor since 1789. The maltreatment of all agricultural interests in England dates only from the acquisition of political supremacy by the manufacturer and of an industrial proletariat fed on imported corn and meat. Even in Russia Lenin found himself and his complicated schemes defeated by the peasant proprietor.

Modern Democracy Inimical.—Generally speaking, however, the most formidable enemy of civil liberty is modern democracy, which standardizes the modern citizen by such means as alleged education and the diffusion of so-called non-controversial information. Democracy in so far as it professes to represent the general will of the modern community is the most formidable enemy to the expression of public opinion.

Self-confessed monarchy, aristocracy or oligarchy at least pays homage to the duty of representing to some extent public opinion. Perhaps the simplest form of oligarchy is the governing body which rules the islanders of Barbados and which submits all legislative and executive measures to the vote of an assembly which either accepts or rejects it like an ordinary debating society. The vote is of course controlled to some extent by respect for the public opinion of the islanders as a whole and represents public opinion far more effectively than the resolutions of a democratic caucus forced on an electorate which usually has to choose between two equally distasteful proposals and is now in some countries threatened by penalties to enforce compulsory voting. The more virile population of France has in the 20th century protested by a general agreement not to vote either for or against the unpopular and often corrupt proposals of the modern politician.

Tendency of Science and Industry.—The exploitation of the herd instinct by modern democracy is to some extent reinforced by modern exponents of physical science; who are content to regard mankind in the mass as suitable subjects for scientific experiments, so that nowadays there is a growing danger of anyone who displays unusual individuality being condemned by a magis-

trate to undergo some crazy kind of hypnotism by the latest exponents of what passes under the name of social welfare. This tendency is also supplemented by the Calvinistic tendencies of modern industry by reason of which the individual worker becomes involved on the political side in what Mr. Belloc calls the servile State and in his private life in the social conventions which his employer considers necessary to mass production. For such a person any unfortunate matrimonial quarrel or entanglement with a policeman on the prowl is sufficient to destroy all prospect of continuing his present employment or of becoming anyone else's hired man while the spoon-fed character of his training from early youth destroys the sort of virility which enabled the French to build houses for themselves after the World War without State subsidies or supervision.

Present Safeguards Inadequate.—Artists of every sort may always be expected to defend civil liberty, and in so far as the press has any political influence it may be expected that doctrines of civil liberty will be propagated by journalists even when they are repudiated by politicians. Again, the peasant proprietor and the small investor are the firmest bulwark against Socialism, for it must never be forgotten that civil liberty is bound up with property and responsibility. One cannot ignore the possibility of Communism ultimately succeeding in Russia and something very like it in Japan. In that case it might easily spread to the rest of the world and Communism is to-day as formidable a factor in the world as the counter-Reformation and Jesuit movement were at the end of the 16th century.

One is forced to admit that the traditions and existence of civil liberty can only be the result of a mature civilization and are therefore frail in the sense that any mature civilization is frail. Any student of history must be painfully aware of the ease with which the crude and bestial instincts of the mob all through the ages succeed in destroying the delicate achievements of human intelligence and no nation can consider itself immune from ever-present danger. The respect for civil liberty is the touchstone of everything for which any civilization worthy of the name stands; it is a capital example of all those values which civilization has taught us to consider essential to the art of living and which are highly disinterested in the sense that they are divorced from all vulgar appetites for power or territory or loot. It is this appetite which breaks out from time to time among the lower orders of mankind, and when it succeeds in destroying the old traditions for any long period of time the resurrection of such a sentiment as that of civil liberty becomes fairly hopeless. (E. S. P. H.)

UNITED STATES

The Constitution of the United States did not create civil liberty. The American code expressed traditions which had existed for centuries in Anglo-Saxon life. The Puritan Congregationalism enlarged its Church democracy into a State democracy as it then was unable to do in England. In the 13 colonies the shades of civil liberties varied greatly. Freedom of speech, press, public assemblage and the liberty of religious worship had different connotations in each State. The antecedents were the Magna Carta, 1215, the Statutes of Westminster, 1275, the Petition of Right, 1628, Bushell's Case, 1670 (trial by jury), the Habeas Corpus Act, 1679, the Bill of Rights, 1688, and the Act of Settlement, 1701. In many respects the American Constitution merely copied words and phrases from these historic documents. The rights of the American Constitution were of English origin, but the principles were the opposite to the English. The English statutes did not recognize general rights of man and they had neither the power nor the intention to establish principles for future legislation. The American theory created the myth of natural rights for a mythical man in a state of nature and then allowed this mythical man to cede certain of his powers to the common interest. At the time of the formation of the Government of the United States there was a real clash of opinion on the question of intellectual freedom, a clash much influenced by the French Revolution, and exemplified by the fact that Jefferson, who wrote the Declaration of Independence, was not a member of the convention that framed the Constitution. Hamilton, typifying the philosophy of Government

control and popular suppression of thought, dominated the situation. Contrary to the general belief in the United States, the Constitution itself is barren of any declaration of civil liberty. In fact, the adoption of the Constitution (1788) was bitterly opposed in many States because of such omission and in fact, one State never ratified it. In 1791 civil liberties were impressed in the Constitution by the first ten amendments known as the Bill of Rights. But even after the adoption of the Bill of Rights, it must be noted that civil liberty, as there enunciated, had its own contemporary and peculiar definitions. The course of changes in the various spheres of liberty can be separately traced.

Postal Censorship.—All of the Fathers of the country were opposed to control of intellectual thought through the use of the post office, and to prevent this Washington urged that the mails be carried without postal charges. By 1840, in spite of the opposition of Clay, Calhoun and Webster, postal censorship had started to creep in as an aid to the slave States in the battles against the Abolitionists. The Federal Government, in the '70s, also adopted the power of censoring the morals of the people by the so-called Comstock Act, forbidding the use of the mails to obscene matter. The dwindling church power had transformed obscene blasphemy to blasphemous obscenity, and the obscenity laws were soon used for political ends. After the Civil War the press was molested to such an extent by the Federal Government that many papers were forced to suspend and even a paper like the *Christian Observer* was taken over by the Government. This power developed ultimately to such an extent that during the World War the post office became a real censor of the press. Public opinion in opposition to the war or even in opposition to the view of the party in power was barred from the mails—in spite of the fact that the Federal Government as such was deemed to rest upon the theory that as a Federation it had no concern with the morality of the people.

Religion.—The constitutional provisions provided equality only between the Christian sects. Agnostics, Catholics, Jews, Mohammedans and all other minority religious groups were subject to admitted discriminations. For a period of more than 50 years in various States, Jews or Catholics were unable to hold public office, and non-Christians in large areas of the country were prevented from giving court testimony against Christians. The Mormon persecutions were founded on religious and marital grounds. The recent weakening of ecclesiastic powers has caused the growth of religious political tolerances, even to non-believers.

Racial Minorities.—It required the Civil War to give real meaning to the idea of freedom as affecting the black people. Lynchings in the United States between 1889 to 1918 totalled 3,024 victims of whom 2,522 were coloured people. Of this number, 219 were in the North, 156 in the West, 15 in Alaska, 2,834 in the South. Since the war the lynchings are diminishing in number, and the violent impairment of Chinese liberties in California has been controlled, although President Taft cited that 50 Chinese were killed by mobs and 120 wounded or robbed from 1885 to 1910. The denial of the franchise to negroes has continued in open violation of the constitutional amendments. Attempts to limit the residences and property ownership of negroes and orientals proceed (1928) in spite of declarations of the courts.

Conscientious Objectors.—The rights of conscientious objectors were toyed with in the Civil War by the establishment of a money value—\$300 being needed to buy one's way out of the army. At that time Quakers were given a preferential position which they maintained even during the World War. In this latter war men were incarcerated as conscientious objectors even though serious attempts were made by the Government to provide non-combatant service for those whose religious scruples led them to oppose killing by war.

Labour.—The impairment of civil liberties for labour became acute in about 1870 when the use of the injunction in labour disputes developed as an advantageous weapon to prevent picketing, assemblage and free speech. In the realm of industrial disputes martial law has been used very frequently and in one State, Colorado, it was invoked 11 times between 1894 and 1928.

Educational.—In this realm the Supreme Court of the United States has declared illegal the attempts of the States to drive out

the parochial schools or to prevent the teaching of German in public schools. On the other hand when the law excluding the theory of evolution from public institutions came up as a test case in Tennessee in the Scopes case, a higher court evaded the question by reversing the conviction without declaring the statute unconstitutional.

Political Refugees.—Until after the World War, the United States was a glorious haven for political outcasts who had left their lands because of political suppression. Since the war, Karolyi, the former president of Hungary, and many other eminent Europeans have been excluded merely because they held certain political philosophies. The immigration and deportation statutes have been directed against anarchists and communists because of their philosophical concepts even in the absence of overt acts.

Sedition.—Reaching back to the Alien and Sedition Acts of 1797 as examples, 34 States since 1917 have enacted similar laws and between 1917 and 1928 more than 350 persons were sent to jail for mere beliefs—no overt acts being committed.

Miscellaneous.—At various times plays, pictures and books have been suppressed on grounds of obscenity even though the real attack was against some heretical or seditious idea. The censorship of motion pictures is in line with this theory. In the United States as elsewhere minority groups have always had to struggle for their civil liberties—the combat becoming severe only when the new ideas endangered the old. The Supreme Court of the United States has whittled away the Jeffersonian ideology of civil liberty but always in the 20th century against the dissenting voices of Judges Holmes and Brandeis. To protect all minorities in their rights of speech, press, assemblage and religion, the American Civil Liberties Union was organized with nation-wide membership. The comment in the press indicates a feeling that England exceeds the United States in civil liberties in political fields, France in personal individualisms; while on the other hand Russia, Italy, Hungary and other present dictatorships have far less civil liberty than exists in America.

CIVIL LIST, the English term for the account in which are contained all the expenses immediately applicable to the support of the British sovereign's household and the honour and dignity of the crown. An annual sum is settled by the British parliament at the beginning of the reign on the sovereign, and is charged on the consolidated fund. But it is only from the reign of William IV. that the sum thus voted has been restricted solely to the personal expenses of the crown. Before his accession many charges properly belonging to the ordinary expenses of government had been placed on the Civil List.

William and Mary.—The history of the Civil List dates from the reign of William and Mary. Before the Revolution no distinction had been made between the expenses of government in time of peace and the expenses relating to the personal dignity and support of the sovereign. The ordinary revenues derived from the hereditary revenues of the crown, and from certain taxes voted for life to the king at the beginning of each reign, were supposed to provide for the support of the sovereign's dignity and the civil government, as well as for the public defence in time of peace. Any saving made by the king in the expenditure touching the government of the country or its defence would go to swell his privy purse. But with the Revolution a step forward was made towards the establishment of the principle that the expenses relating to the support of the crown should be separated from the ordinary expenses of the State. The evils of the old system under which no appropriation was made of the ordinary revenue granted to the crown for life had been made manifest in the reigns of Charles II. and James II.; it was their control of these large

revenues that made them so independent of parliament. Moreover, while the civil government and the defences suffered, the king could use these revenues as he liked.

The parliament of William and Mary voted in 1689 an annual sum of £600,000 for the charge of the civil government. This was a mere resolution without statutory effect. In 1697 the first Civil List act was passed. Certain revenues (the hereditary revenues of the crown and a part of the excise duties), estimated to yield £700,000, were assigned to the king to defray the expenses of the civil service and the payment of pensions, as well as the cost of the royal household and the king's own personal expenses or "Privy Purse." The Civil List meant practically all the expenses of government except the debt charge and defence. If the yield of the assigned revenues exceeded £700,000 the surplus was to be disposed of by parliament. This restriction was removed by an Act of 1700. In the reign of Anne the Civil List consisted of the same assigned revenues (subject to certain deductions). The yield fell short of the estimate of £700,000, and at the end of the reign a debt of £500,000 was met from the Exchequer.

The Hanoverians.—For George I. additional revenues were assigned, and it was enacted in effect that the Civil List should become independent of the yield of the assigned revenues, and should be a fixed sum of £700,000 a year. Any surplus was to be surrendered, and any deficiency would be made good. But this was found insufficient and parliament from time to time made additional grants from the Exchequer to pay off debts amounting in the aggregate to £1,300,000. In the reign of George II. there was again a change of system. The Civil List was composed of the assigned revenues, together with certain fixed grants, and a *minimum* yield of £800,000 was guaranteed by parliament. Any surplus yield over £800,000 was retained by the king. On the accession of George III. the system of a fixed Civil List was reverted to. The assigned revenues were no longer paid to the crown but to the aggregate fund as part of the revenues of the Exchequer, and the fixed allowance of £800,000 was paid out of the aggregate fund to the king (subject to certain annuities payable to members of the royal family).

During the reign of George III., the Civil List played an important part in the king's effort to establish the royal ascendancy. The "king's friends," his supporters in parliament, were lavishly rewarded with places, pensions and even bribes. Upon the expenditure of the Civil List there was no independent check. So long as the total was not exceeded, the king, with the co-operation of complaisant ministers, was free to spend it as he pleased. As it turned out, despite stringent economies in the cost of the household, excesses were incurred. But parliament, already corrupted, was persuaded to provide extra funds to pay off the debts (£513,511 in 1769 and again £618,340 in 1777). Proposals for enquiry, supported by Chatham, were resisted and negatived.

Burke had already attacked the extravagance and corruption of the Civil List and in 1780 he introduced bills embodying his scheme of economic reform. The scheme could not be passed against Lord North's government, but in 1782 the Rockingham ministry passed a Civil List act which abolished many useless offices, imposed restraints on the issue of secret service money, stopped secret pensions payable during the king's pleasure, and provided for a more effectual supervision of the royal expenditure.

The Civil List was divided into classes, and the requirements of each were estimated as follows by a committee of 1786:—

| | |
|---|----------|
| 1. Pensions and allowances of the royal family | £203,500 |
| 2. Salaries of Lord Chancellor, judges and Speaker | 32,955 |
| 3. Salaries of ministers to foreign courts | 70,852 |
| 4. Tradesmen's bills, etc., for His Majesty's service | 147,200 |
| 5. Menial servants of the household | 90,966 |
| 6. Pensions | 118,189 |
| 7. Other salaries | 81,440 |
| 8. Salaries and pensions of Commissioners of the Treasury | 13,822 |
| Occasional payments | 138,476 |
| | £897,400 |

Substantially classes 1, 4 and 5, amounting to £431,666, represented what is now covered by the Civil List and the annuities

to the royal family, though a few items in class 4 belonged to the cost of government, and a few in class 6 and among the occasional items would now come under the Civil List. These estimates for the several classes were not binding, and they were in fact soon exceeded. Indebtedness accumulated and had from time to time to be paid off (£2,266,000 in all between 1782 and 1820). The amount of the Civil List itself was augmented, and in 1816 it was fixed at £1,083,727. Meanwhile the principal provision for the civil government had come to be made outside the Civil List. Annual votes of parliament for what were called miscellaneous services had been between £200,000 and £300,000 in the earlier years of George III.'s reign, and had been mainly casual and non-recurrent. By 1820 they amounted regularly to about £2,000,000 a year. On the accession of William IV. in 1830, the Civil List was finally freed from all charges for the government service as distinguished from the court and royal family. The charges for judicial and diplomatic salaries and for the Board of Treasury were transferred to the Exchequer. The expenses left were covered by a Civil List of £510,000. This included a sum of £75,000 for pensions.

Civil List Pensions.—The pensions were excluded from Queen Victoria's Civil List, which was reduced to £385,000 (separate provision of £100,000 being made for Queen Adelaide, who had had a privy purse of £50,000 during her husband's reign).

A new system of "Civil List Pensions" was set on foot. The queen might, on the advice of her ministers, grant pensions up to a limit of £1,200 granted in any one year, in accordance with a resolution of the House of Commons of Feb. 18, 1834, "to such persons as have just claims on the royal beneficence or who, by their personal services to the crown, by the performance of duties to the public, or by their useful discoveries in science and attainments in literature and art, have merited the gracious consideration of the sovereign and the gratitude of their country." The pensions in course of payment at any one time usually amount to about £24,000. The list of pensions must be laid before parliament every year.

Queen Victoria to George V.—The Civil List has continued since 1837 substantially on the same footing. The sums granted and the division into classes have been the following:—

| | Victoria 1837 £ | Edward VII. 1901 £ | George V. 1910 £ |
|--|-----------------------|--------------------------|------------------------|
| Privy purse | 60,000 | 110,000 | 110,000 |
| Salaries and retired allowances of household | 131,260 | 125,800 | 125,800 |
| Expenses of household | 172,500 | 193,000 | 193,000 |
| Works | | 20,000 | 20,000 |
| Royal bounty and special service | 13,200 | 13,200 | 13,200 |
| Unappropriated | 8,040 | 8,000 | 8,000 |
| | £385,000 | £470,000 | £470,000 |

The addition of £50,000 to the privy purse for King Edward VII. and for the present King was to provide in each case for the Queen Consort. The new class for works introduced in 1901 was partly composed of an item previously included under expenses, and partly of expenditure previously voted by parliament. The reduction in salaries was due to the abolition of the post of Master of the Buckhounds, and some other reductions of establishments and emoluments. The allocation among classes is not absolutely binding, in that savings on one class can be applied to meet excesses on another (or added to the privy purse) with the consent of the Treasury. Class v. (works) is an exception, savings upon it being accumulated for future years.

No change was made either in the total or the details on the accession of the present King in 1910, but there was a slight change of practice introduced. In 1842 Queen Victoria, though under no legal or constitutional obligation to pay taxes of any kind, undertook voluntarily to pay income tax. King Edward continued the voluntary payment. King George V. agreed with the government of the day that it should be discontinued, but in exchange placed on the Civil List the cost of State visits of foreign royalties previously defrayed from public funds. In 1916

the King made a voluntary gift of £100,000 towards the cost of the World War. In addition to the Civil List the King receives the revenues of the duchy of Lancaster. The revenues of the duchy of Cornwall belong to the prince of Wales as duke of Cornwall. Other members of the Royal Family receive statutory annuities from the consolidated fund, outside the Civil List.

At the beginning of a new reign it is the practice for the House of Commons to appoint a select committee to make recommendations for the Civil List and the annuities to the royal family. Constitutionally the settlement is still regarded as in the nature of a bargain for the surrender of the hereditary revenues to parliament (*see* preamble of the Civil List act 1910). The accounts of the Civil List are passed by an auditor appointed by the Treasury under the Civil List Audit act, 1816. He is always a high officer of the permanent staff of the Treasury, sometimes the Permanent Secretary himself. (R. G. H.)

CIVIL SERVICE, the generic name given to the public servants of a State employed in a civil capacity. It is the machinery by which the executive, through successive administrations, carries on the government of the country. The term is usually limited to officials of the central Government, but in France and certain other countries it includes persons employed by municipalities and other local authorities.

Great Britain.—Apart from workpeople employed in the dockyards and other Government industrial establishments, the civil service in 1927 consisted of some 300,000 persons spread over more than 80 departments, the post office alone accounting for more than 190,000. (Cmd. 2,972, 1927.)

The number of women civil servants in 1927 exceeded 70,000. Women are now admitted on equal terms with men to compete for appointment to the various branches of the public service. Certain obstacles to their employment as civil servants were removed by the Sex Disqualification (Removal) Act, 1919; and on Aug. 5, 1921, the Government accepted a resolution of the House of Commons providing *inter alia* that, after a period of three years, women should be admitted to the civil service in Great Britain under the same regulations as applied to men.

Responsibility for the general administration of the civil service is now formally vested in the Treasury: this department being empowered by an Order in Council of July 22, 1920, to "make regulations for controlling the conduct of His Majesty's civil establishments and providing for the classification, remuneration and other conditions of service of all persons employed therein." In accordance with the recommendations of the Royal Commission on the Civil Service 1914 (Cd. 7,338, 1914), and of the Haldane committee on the machinery of government, 1918 (Cd. 9,230, 1918), a special department of the Treasury was constituted in 1919 to deal solely with questions bearing on the organization of the public service and the conditions of employment of civil servants. In all such matters the Treasury acts in close consultation with the various departments, each of which is held directly responsible for the efficiency of its own staffing arrangements.

The duty of selecting candidates for admission to the civil service rests with the civil service commissioners. This authority was first established by an Order in Council of May 21, 1855, for the purpose of conducting "the examination of the young men proposed to be appointed to any of the junior situations in the civil establishments." The introduction in 1870 of the principle of open competition has led to a wide extension of the commissioners' jurisdiction. It is now provided by the Order in Council of July 22, 1920, that "the qualifications of all persons proposed to be appointed, whether permanently or temporarily, to any situation or employment in any of His Majesty's civil establishments, shall, before they are appointed, be approved by the commissioners": the only exceptions to this rule being certain specified situations to which the holder is appointed directly by the Crown, situations filled in ordinary course of promotion, and certain classes of temporary situations, for the most part in subordinate grades.

Since 1906 when the postmaster-general announced that he would "frankly recognize any duly constituted association or

federation of postal servants," almost all classes of civil servants have formed themselves into organizations for the purpose of dealing with the various departmental authorities on matters affecting their conditions of service. In 1919, following on the reports of the Whitley committee on relations between employers and employed (Cd. 8,606, 1917, and Cd. 9,002, 1918) trade joint councils and departmental joint councils were established for the consideration of wages and other conditions of employment in Government industrial establishments; and shortly afterwards, on the recommendation of a provisional joint committee on the application of the Whitley report to the administrative departments of the civil service, it was decided to set up a national council, departmental councils and district and office committees for the discussion and settlement of matters affecting the conditions of service of the staffs of those departments. The national council, which deals with general as distinct from departmental questions, consists of 54 members, appointed in equal numbers by the Government and by groups of staff associations (Cmd. 198, 1919).

As a result of an agreed settlement reached by a committee of the national council, the general administrative and clerical work of the civil service is now provided for by the recruitment of four main classes of officers, viz., a writing assistant class for the simple mechanical work, a clerical class for such work as consists in the application of well-defined regulations, decisions and practice to particular cases, an executive class for the higher work of supply and accounting departments and of other executive or specialized branches, and an administrative class for duties concerned with the formation of policy, with the co-ordination and improvement of Government machinery and with the administration and control of departments of the public service. The writing assistant class is recruited from among girl candidates by local competitive examinations with age limits of 16 to 17; whilst the age limits and subjects of examination for open competitions for admission to the clerical, executive and administrative classes are determined with reference to the standard of development reached, respectively, at the end of the intermediate stage of a secondary school course, on completion of a secondary school course and on completion of an honours course of a university.

In accordance with the provisions of a scheme recommended by a committee of the national council, part of the pay of civil servants in Great Britain takes the form of a bonus fixed on the basis of the official cost of living figure. Bonus is not payable to civil servants with salaries of £2,000 a year and over, and below that limit is graduated so that the rate of bonus decreases as salaries increase. It is subject to review every six months in accordance with fluctuations in the cost of living figure.

Pensions and retiring allowances are granted to established civil servants retiring on the ground of age, ill-health or abolition of office. For male civil servants the Superannuation Act, 1909, prescribes annual pensions of one-eightieth of salary for each year of service, together with a lump sum allowance equal to one-thirtieth of salary for each year of service; and under this act as amended by the Superannuation Act 1914, a gratuity is payable in the event of death during service at the rate of a year's pay or the amount, if greater, of the lump sum allowance that would have been due to the civil servant if at the date of his death he had been invalided from the service. Established women civil servants are pensionable under the Superannuation Act, 1859, which prescribes a scale of sixtieths, but makes no provision for lump sum allowances or death gratuities.

A conciliation and arbitration board for the civil service, established in 1917, came to an end in 1921; but in 1925 new machinery for the same purpose was set up under the Industrial Courts Act, 1919. The court so established, described in a Treasury letter No. 6/25 of March 14, 1925, is empowered to deal with "claims affecting emoluments, weekly hours of work and leave of certain classes of civil servants." Cases of individual officers are excluded from the competence of the court. The official announcement says that "subject to the over-riding authority of parliament, the Government will give effect to the awards of the court."

It is a well recognized rule of the civil service that civil servants shall not take an overt part in political controversy; and they are prohibited by Order in Council from becoming candidates for parliament whilst still in the service (Cd. 2,408, 1925). Section 5 of the Trades Union and Trades Disputes Act, 1927, provides that established civil servants may not be members of any trade union unless it consists solely of civil servants, is independent of outside trade unions and political parties and organizations, and is free of political objects.

Northern Ireland.—The civil service of Northern Ireland, numbering approximately 1,850, is organized on the same general principles as that of Great Britain, and is for the most part subject to the same general rules.

BIBLIOGRAPHY.—Sir W. R. Anson, *Law and Custom of the Constitution; The Reports of the Royal Commission on the Civil Service* (Cd. 7,338, 1914, etc.); *Report of H.M. Civil Service Commissioners on the year 1926*; special studies of separate departments in the Whitehall Series, beginning with *The Home Office*, by Sir E. Troup (1925); H. Finer, *The British Civil Service* (1927).

BRITISH DOMINIONS AND COLONIES

In the self-governing dominions and colonies the civil service is controlled by the Government of the dominion or colony in question. In colonies not possessing responsible government the civil service is partly recruited from among local candidates, but the higher officials are appointed directly through the Colonial Office.

Canada.—Competitive examinations were made effectual for the inside service by the Civil Service Act of 1908 which created a board of commissioners; and the same principle was established for the outside service by the Act of 1918. Provision for a contributory system of superannuation is made by the Acts of 1924-27. The Act of 1918, as amended by later legislation, contains most of the existing regulations in regard to political rights, promotion, dismissal, etc. Permanent and temporary employees of the Government of Canada numbered 39,097 in 1926. (See R. M. Dawson, *The Principle of Official Independence* [1922], ch. iii., "The Civil Servant," and *Canada Year Book*, 1926.)

Commonwealth of Australia.—The Public Service Act, 1922-24, governs the situation. The Act of 1922 established a board of commissioners for the public service with extensive powers, and responsible to parliament. The Arbitration (Public Service) Act, 1920, established a public service arbitrator, holding office for seven years, for giving awards on claims from associations of public servants; but this Act of 1920 appears to conflict in some particulars with the Act of 1922, in regard to the powers of the board, whose decisions may be varied by the public service arbitration court.

There is a system of contributions towards a superannuation fund under the Superannuation Act, 1922-24. In 1924-25 the number of civil servants in Australia, including teachers, police and railway and tramway employees, was 216,031, of whom 27,375 were in the Commonwealth service. (See *Reports of the Public Service Board of Commissioners*, 1924-26, and *Official Year Book of the Commonwealth*, 1926.)

New Zealand.—The Public Service Act 1912 places the service generally under a commissioner and two assistants, appointed for seven years and responsible only to parliament. The Government railway service is an exception, and the Postal and Telegraph Act 1918 excludes those services from the authority of the commissioner, except in regard to making appointments. There are contributory superannuation funds under Acts of 1926 and 1927. Permanent officers of the State numbered about 28,000 in 1925. (See *Year Book of New Zealand*, 1927.)

Union of South Africa.—The Public Service and Pensions Act 1923, as amended by Acts 44 of 1926 and 27 of 1927, together with regulations issued thereunder provides for the organization of the public service. There is an advisory council representing associations of public servants which gives advice to the public service commission, when asked. The commissioners have the extensive powers usual in the dominions. The staff employed in the Union Government service in 1924 was 35,505. (See *Official Year Book of the Union*, 1925.)

Irish Free State.—The Civil Service Regulation Acts 1924 and 1926 provide for the appointment by the executive council of not more than three commissioners, and define their duties and powers, in the exercise of which the consent of the minister for finance is frequently necessary. Superannuation and pensions are regulated by the Free State Acts of 1923 and 1925, and earlier legislation.

British India.—The services are now classified as All India, Central, Provincial and Subordinate, of which the last two are recruited entirely in India and the Central services almost entirely, leaving the All India services (namely, the Indian civil service, Indian police service and Indian forest service and Indian service of engineers) with some few technical appointments as the only services for which recruitment is made in Great Britain, these also being Indianized to a considerable extent.

This "increasing association of Indians in all branches of the Administration" formed part of the policy of reforms to which the Government of India Act of 1919 gave legislative form.

Two royal commissions, the Islington commission (Cmd. 8,382, 1917) and the Lee commission (Cmd. 2,128, 1924) resulted in certain changes of organization and in a general increase in pay, leave and pensions to meet changed economic conditions. As a result of the report of the latter commission there was set up a public service commission under the central Government which was charged with certain functions in connection with recruitment in India and with others as an advisory body on service matters. The conditions of service of the civil services in India are regulated by statutory rules, made under section 96B of the Government of India Act, of which the most important are reprinted annually in the India Office list of the year. (See Sir M. C. C. Seton, *India Office* [1927], ch. viii.-xii.)

EUROPEAN COUNTRIES

France.—The number of civil servants in 1921 was 896,000, not including workers on the State railways. These numbers cannot be compared with those given for Great Britain, because in France they include judicial and local government officials, and teachers. The organic laws of 1875 empower the president to nominate for all posts in the service, and the rules for entry, etc., are administered finally by the *Conseil d'Etat*. Examinations are held for most posts, and a university degree is in some cases necessary for entry. In the highly centralized nature of the French administration lies the chief reason for the difference in the general character of the French and British civil services.

The *Conseil d'Etat*, apart from its functions as court of appeal in cases of administrative law, is a central advisory body of permanent civil servants which the Government is obliged to consult prior to many kinds of administrative action. The *Conseil d'Etat's* advice does not necessarily bind the Government, and it is secret.

The cabinet of a minister is a small body of officials chosen by a minister as a private secretariat. These officials need not necessarily be permanent civil servants. They often exercise a very important control over policy.

A long controversy is connected with the right to trade union organization among civil servants. The problem has been discussed in the two chambers on several occasions during the last few years. No definite decision has ever been taken, though a statement made by M. Poincaré, when president of the council in 1927 seems to recognize the right of association provided it is not used against the interests of the State. In any case, in practice, the *Fédération des Fonctionnaires* is a powerful body. (See H. Barthélemy, *Traité élémentaire de droit administratif*, 10th ed., 1923; J. Barthélemy, *Le Gouvernement de la France*, 1924.)

Germany.—The status of German civil servants is defined by Articles 128, 129, 130, 143 and 176 of the Weimar Constitution. An oath of allegiance to the Republican Constitution is obligatory. Although the railways and the post office have become quasi-private undertakings the number of pensionable civil servants has much increased since 1914. Despite recent reductions, federal civil servants numbered 92,722 in 1927, as against 19,200 in 1913. The financial administration alone employs 71,300 of

these owing to the transfer of financial administration from the States to the Federal Government. This transfer has not however caused a corresponding decrease in the civil departments of the respective States. In Prussia, for instance, there are to-day 141,000 civil servants as against 88,000 in 1913. Women are eligible for all posts of the civil service, the higher judicial appointments excluded. Civil service unions are denied the right to strike. (See H. Oppenheimer, *The Constitution of the German Republic*, 1923.)

The League of Nations.—An important development since the war has resulted in the establishment of an international civil service. It is true that ever since the middle of the 19th century, for example in the office of the Universal Postal Union since 1870, there have been small numbers of officials under authorities representing the joint action of sovereign States; but the establishment of the League of Nations and its International Labour Organization has considerably modified the situation. There are now 581 officials of the League in Geneva and elsewhere and 361 officials of the Labour Organization. Their work is partly to carry out the decisions of the Assembly and the Council of the League of Nations, the governing body of the Labour Office and other international councils, or committees, and partly to co-ordinate the activities of the Governments of the States in the League. The League civil service thus forms an integral part of the whole machinery of government.

The civil service of each of the fully developed States is now in contact with the relevant services of the other fully developed States, since it is now recognized in practice that the work, for example, of public health organization cannot be effectual unless there is co-operation between States. The League officials, therefore, are a necessary inter-connection of the parts of modern administration. The higher appointments are usually made by selection from those having a previous record in national administrative work or other appropriate occupations; the minor are made after competitive examinations. But apart from competence, some regard is paid to nationality. In 1928 there were 50 different nationalities in the League secretariat. Of the 581 officials 160 are British (including the dominions), 101 French, 154 Swiss, 26 Italians, 14 Germans, etc.

See *Annual Reports* on the budget of the League and of the director of the International Labour Organization. (R. R. S.)

UNITED STATES

Civil service reform began in America in the latter half of the 19th century. Personal and partisan government, with all the entailed evils of the patronage system, culminated in Great Britain during the reign of George III., and was one of the causes of the American Revolution. Trevelyan characterizes the use of patronage to influence legislation, and the giving of colonial positions as sinecures to the privileged classes and personal favourites of the Administration, by saying, "it was a system which, as its one achievement of the first order, brought about the American War, and made England sick, once and for all, of the very name of personal government."

It was natural that the founders of the new Government in America, after breaking away from the mother-country, should strive to avoid the evils which had in a measure brought about the revolution. Their intention that the administrative officers of the Government should hold office during good behaviour is manifest, and was given thorough and practical effect by every administration during the first 40 years of the life of the Government. The Constitution fixed no term of office in the executive branch of the Government except those of president and vice-president; and Madison, the expounder of the Constitution, held that the wanton removal of a meritorious officer was an impeachable offence.

The Spoils System.—Not until nine years after the passage of the Four Years' Tenure of Office Act in 1820 was there any material departure from this traditional policy of the Government. This act (suggested by an appointing officer who wished to use the power it gave in order to secure his own nomination for the presidency, and passed without debate and apparently without any

adequate conception of its full effect) opened the doors of the service to all the evils of the spoils system. The foremost statesmen of the time were not slow to perceive the baleful possibilities of this legislation, Jefferson, Webster, Clay, Calhoun, Benton and many others being recorded as condemning and deploring it in the strongest terms. The transition to the spoils system was not, however, immediate, and for the next nine years the practice of reappointing all meritorious officers was practically universal; but in 1829 this practice ceased, and the act of 1820 lent the sanction of law to the system of proscriptions which followed, which was a practical application of the theory that "to the victor belong the spoils of the enemy."

In 1836 the provisions of this law, which had at first been confined mainly to officers connected with the collection of revenue, were extended to include also all postmasters receiving a compensation of \$1,000 per annum or more. It rapidly became the practice to regard all these four years' tenure offices as agencies not so much for the transaction of the public business as for the advancement of political ends. The revenue service, which had been used for political purposes merely, came to be used for corrupt purposes as well, with the result that in one administration frauds were practised upon the Government to the extent of \$75,000,000. The corrupting influence permeated the whole body politic. Political retainers were selected for appointment not on account of their ability to do certain work but because they were followers of certain politicians; these "public servants" acknowledged no obligation except to those politicians, and their public duties, if not entirely disregarded, were negligently and inefficiently performed. Thus grew a saturnalia of spoils and corruption which culminated in the assassination of a president.

Acute conditions, not theories, give rise to reforms. In the congressional election of Nov. 1882, following the assassination of President Garfield as an incident in the operation of the spoils system, the voice of the people commanding reform was unmistakable.

The Act of 1883.—Although attempts at reform had been made earlier, the demand became really articulate in New York in 1877 by the formation of the New York Civil Service Reform Association. Other such associations appeared in Boston, New Haven, Philadelphia, Baltimore and other cities. The National Civil Service Reform League was formed by representatives of various of these local associations at a meeting in Newport, R.I., in Aug. 1881. This organization led the fight for the passage of the act of 1883 and is still active in the effort to extend the merit system in States and cities as well as in the Federal Government. After the enactment of the Federal civil service law, one of its chief defenders was Theodore Roosevelt.

Congress assembled in Dec. 1882, and during the same month a bill looking to the improvement of the civil service, which had been pending in the Senate for nearly two years, was finally taken up and considered by that body. In the debate upon this bill its advocates declared that it would "vastly improve the whole civil service of the country," which they characterized as being at that time "inefficient, expensive, and extravagant, and in many instances corrupt." This bill passed the Senate on Dec. 27, 1882, and the House on Jan. 4, 1883, and was signed by the president on Jan. 16, 1883, coming into full operation on July 16, 1883. Now the national civil service law, it was the result of years of effort upon the part of public-spirited men, prominent among whom were Thomas Allen Jenckes, Charles Sumner, George William Curtis, Dorman B. Eaton, Carl Schurz, Everett P. Wheeler and Samuel S. Cox.

The law provides for the observance of the following fundamental principles, "as nearly as the conditions of good administration will warrant" (1) selection by competitive examination for all appointments to the classified service, with a period of probationary service before absolute appointment; (2) apportionment among the States and Territories, according to population, of all appointments in the departmental service at Washington; (3) freedom of all the employees of the Government from any necessity to contribute to political campaign funds or to render political services. For putting these principles into effect the civil service

commission was created, and penalties were imposed for the solicitation or collection, in a Government building or establishment, from government employees of contributions for political purposes, and for the use of official positions in coercing political action. The commission, in addition to its regular duties of aiding in the preparation of civil service rules, of regulating and holding examinations, and certifying the results thereof for use in making appointments and of keeping records of all changes in the service, was given authority to investigate and report upon any violations of the act or rules. The classified service to which the act applies has grown, by the action of successive presidents in progressively including various branches of the service within it, and by natural growth of established governmental activities and the creation of new ones, from 13,924 positions in 1883 to some 425,000 in 1928, constituting about 75% of the entire civil service of the Government and including practically all positions above the grade of mere labourer or workman to which appointment is *not* made directly by the president with the consent of the Senate.

In order to provide registers of eligibles for the various grades of positions in the classified service, the U.S. civil service commission holds as they are needed about 1,700 different kinds of examinations. In the work of preparing these examinations and of marking the papers of competitors in them the commission is authorized to avail itself, in addition to its own corps of trained men and women, of the services of the scientific and other experts in the various executive departments, and is provided with a fund from which it may employ special experts, not in the Government service, for short periods as needed. In the work of holding the examinations it is aided by about 4,700 local boards of examiners, which are its local representatives throughout the country and are located at the principal post offices, custom houses and other Government offices, being composed of three or more Federal employees in those offices. About 250,000 persons annually compete in these examinations, and between 40,000 and 50,000 of those who are successful receive appointments through regular certification to fill vacancies caused chiefly by death, resignation, removal, retirement and promotion. Persons thus appointed, however, must serve six months, and in some cases a year, on probation before their appointment can be made absolute. At the end of or during this probation, if his service has not been satisfactory, the appointee is simply dropped.

Benefits.—The effects of the Civil Service Act within the scope of its actual operation have amply justified the hopes and promises of its advocates. After its passage, absentee holders of lucrative appointments were required to report for duty or to sever their connection with the service. Improved methods were adopted in the departments, and superfluous and useless work was no longer devised in order to provide a show of employment and a *locus standi* for the parasites upon the public service. Individual clerks were required, and by reason of the new conditions were enabled to do more and better work; and this, coupled with the increase in efficiency in the service on account of new blood coming in through the examinations, made possible an actual decrease in the force required in many offices, notwithstanding the natural growth in the amount of work to be done. Experience proves that the desire to create new and unnecessary positions was in direct proportion to the power to control them, for where the act has taken away this power of control the desire has disappeared naturally. There is no longer any desire on the part of heads of departments to increase unduly the number or salaries of classified positions which would fall by law within the civil service rules and be subject to competitive examinations. Thus the promises of improvement and economy in the service have been fulfilled.

Survivals.—An obstacle to the complete success of the merit system, and one which prevents the carrying forward of the reform to the extent to which it has been carried in Great Britain, is inherent in the civil service act itself. All postmasters at first, second and third class offices, all collectors of customs and collectors of internal revenue and numerous other administrative officers, are appointed by the president and confirmed by the Senate, and are therefore, by express provision of the act, not "required to be classified." The universal practice of treating

these 17,000 or more offices as political agencies instead of as administrative business offices is therefore not limited by the act. Such officers are active in political work throughout the country, and their official position adds greatly to their power to affect the political prospects of the leaders in their districts.

Accordingly the Senate, from being, as originally intended, merely a confirming body as to these officers, has become in a large measure, actually if not formally, a nominating body, and holds with tenacity to the power thus acquired by the individual senators. While the civil service commission holds examinations for postmastership at first, second and third class offices under executive order, the salutary restrictions of the civil service law are not applied, and cannot be except by act of Congress; and politics continues to play an important part in the appointment of postmasters at first, second and third class offices, although the examinations are held impartially.

All postmasters at fourth class offices, the smaller offices, are classified under the civil service law. Thorough civil service reform requires that all these administrative positions be made subject to the merit system, for in them is the real remaining stronghold of the spoils system. Even though all their subordinates be appointed through examination, it will be impossible to carry the reform to ultimate and complete success so long as the officers in charge are appointed mainly for political reasons and are changed with every change of administration. A further obstacle has been a tendency upon the part of Congress in recent years to enact laws expressly exempting certain positions from the operation of the civil service law and rules. A notable example of such exemption is an act of Oct. 22, 1913, affecting deputy collectors of internal revenue and deputy marshals.

The purpose of the act to protect the individual employees in the service from the rapacity of the "political barons" has been measurably, if not completely, successful. The power given the civil service commission to investigate and report upon violations of the law has been used to bring to light such abuses as the levying of political contributions, and to set the machinery of the law in motion against them. While comparatively few actual prosecutions have been brought about, and although the penalties imposed by the act for this offence have been but seldom inflicted, still the publicity given to all such cases by the commission's investigations has had a wholesome deterrent effect. Before the passage of the act, positions were as a general rule held upon a well-understood lease-tenure, the political contributions for them being as securely and as certainly collected as any rent. Now, however, it can be said that these forced contributions have almost entirely disappeared. The efforts which are still made to collect political funds from government employees in evasion of the law are limited in the main to persuasion to make "voluntary" contributions, and it has been possible so to limit and obstruct these efforts that their practical effect upon the character of the service is now very small.

States and Cities.—The same evils that the Federal civil service act was designed to remedy exist to a large degree in many of the State and municipal governments. The chief, if not the only, test of fitness for office in many cases has been party loyalty—honesty and capacity being seldom more than secondary considerations. The result has been the fostering of dishonesty and extravagance, which have brought weakness and gross corruption into the administration of the local governments. In consequence of this there has been a constantly growing tendency, among the more intelligent class of citizens, to demand that honest business methods be applied to local public service, and that appointments be made on the basis of merit and fitness, rather than of party allegiance. Generally, those who seek to improve social and economic conditions in States and cities by governmental changes realize that the merit system in the civil service is an essential element to their object. Hence civil service reform is given a leading position in all programmes for the reform of State and municipal governments. This has undoubtedly been due, in the first instance, at least, to the success which attended the application of the merit system to the Federal service. New York was the first State to enact a civil service law, in May, 1883; this

was soon supplemented by one providing the same system for the larger cities of the State.

The operation of the merit system in the State of New York was such as to enable its supporters to contend successfully in the constitutional convention of 1894 for a clause writing the principle of the merit system into the constitution of the State. The wording of this clause has served as a model for other State constitutional clauses. It is: "Appointments and promotions in the civil service of the State, and of all the civil divisions thereof, including cities and villages, shall be according to merit and fitness, to be ascertained, so far as practicable, by examination, which, so far as practicable, shall be competitive."

Massachusetts followed the example of New York, enacting in 1884 a civil service law, applicable to cities as well as to the State Government. There followed years of progress in the perfecting of methods of applying the new system of appointments and promotions, but it was not until 1905 that Wisconsin passed a State law and Illinois made a partial reform, which was extended in 1911. Colorado and Indiana made a beginning in 1907, and New Jersey passed a comprehensive law in 1908. In 1912 Ohio adopted a constitutional amendment in favour of the merit system, and in the following year California adopted a law. Connecticut also in 1913 passed a law, which was later weakened and finally repealed in 1921—the only instance of a State taking this backward step. Kansas placed its State service under the merit system in 1916; but since 1918 no commission has been appointed in Kansas. Colorado adopted a strong constitutional amendment in 1920, and in the same year Maryland passed an effective law.

The progress of the merit system in municipalities has been continuous though slow. In certain States the cities are brought under the operation of the State law—for the laws of the ten States now having civil service laws, as briefly enumerated above, differ widely in scope and effectiveness. In New York and Ohio all cities have their own commissions under the State law. In New Jersey the municipalities adopt the provision of the State law subject to a referendum to the voters (and in only one instance has a referendum in New Jersey been lost). In Massachusetts all cities are under the direct jurisdiction of the State commission. In other States many cities have adopted the merit system by special legislation or charter provision. When the bitter opposition of politicians is considered, it is a distinct cause for encouragement that more than 350 cities of the United States have adopted some form of civil service control. Of the 100 largest cities in the country by the census of 1920, no fewer than 72 have adopted the merit system in whole or in part; and this number includes the 20 cities of largest population.

The application of the merit system to State and municipal governments has proved successful wherever it has been given a fair trial. As experience has fostered public confidence in the system, and at the same time shown those features of the law which are most vulnerable, and the best means for fortifying them, numerous and important improvements upon the pioneer act applying to the Federal service have been introduced in the more recent legislation. This is particularly true of the acts now in force in New York, Massachusetts and New Jersey. The power of the State commissions to enforce these acts is materially greater than that possessed by the Federal commission. One of the most important powers exercised generally by the local commissions, which the Federal commission cannot exercise, is the provision that the payment of salaries is made dependent upon the certificate of the commission that the appointments of the recipients were made in accordance with the civil service law and rules. Thus these commissions have absolute power to prevent irregular or illegal appointments by refractory appointing officers. Their powers being so much greater than those of the national commission, their action can be much more drastic in most cases, and they can go more directly to the heart of an existing abuse, and apply more quickly and effectually the needed remedy to end such irregularities.

Outlying Possessions.—Upon the termination of the Spanish-American War, the necessity for the extension of the principles of the merit system to the new territories, the responsibility for whose

government the results of this war had thrown upon the United States, was realized. By the act providing for civil government in Porto Rico (April 12, 1900), the provisions of the civil service act and rules were applied to that island. Under this legislation the classification applies to all positions which are analogous to positions in the Federal service, those which correspond to positions in the municipal and State governments being considered as local in character, and not included in the classification. A similar law was passed for Hawaii on April 30, 1900.

On Sept. 19, 1900 the United States Philippine commission passed an act "for the establishment and maintenance of an efficient and honest civil service in the Philippine islands." This act, in its general features, is based upon the national civil service law. A just right of preference in local appointments is given to natives. The president of the Philippine commission in introducing this bill said: "The purpose of the U.S. Government . . . in these islands is to secure for the Filipino people as honest and as efficient a government as may be possible. . . . It is the hope of the commission to make it possible for one entering the lowest ranks to reach the highest, under a tenure based solely upon merit." Experience leads to the belief that this law is well adapted to accomplish the purpose above stated.

Recent Changes.—The changes in the Federal civil service since the World War are: (a) an increase in the number of employees, (b) an increase in the proportion of women employed, (c) the extension of the classified service and (d) changes in the laws and regulations. In June 1913, there were 435,000 employees in the Federal civil service, of whom 292,460 had entered by competitive examination. In June 1928, there were 568,715 employees, of whom more than 425,000 were in positions subject to competitive examination under the civil service act. Of the 559,138 employees in 1927 the Post Office department with 308,740 represented 55.22%. The Treasury department employed 51,532 persons in 1927, and the War and Navy departments 42,292 and 43,425 respectively. The Veterans' Bureau had an employment list of 23,696, the department of Agriculture, 21,702, department of the Interior, 16,350 and department of Commerce, 14,964. Since 1916 there has been a substantial decrease in the department of the interior, but an increase of 5,061 in the department of Commerce. The number of government employees in the Panama Canal Zone decreased from 19,291 in 1916 to 9,926 in 1927. Since 1916 many new governmental activities have been established, namely, the Shipping Board, Alien Property Custodian, Tariff Commission, Employees Compensation Commission, Federal Board of Vocational Education, General Accounting Office, Veterans' Bureau, Railway Administration, War Finance Corporation, National Advisory Committee for Aeronautics, Board of Tax Appeals and Board of Mediation. An Act of Mar. 3, 1927 also brought into the classified service all positions in the Prohibition Service except that of Commissioner of Prohibition. Besides these new activities there has been a substantial increase in the amount of work of the older establishments which have necessitated added employees. Of the total employees in 1927 59,800 were located in the District of Columbia.

During the war the number of women was increased, and since 1919 all the examinations under the civil service commission have been open to women. In 1928, about 14% of the employees of the Federal civil service were women. In the District of Columbia 24,545 of the 61,388 employees were women, while outside that district, 55,293 of the 507,327 employees were women. The branches outside the District of Columbia include many large services in which by their nature women are not employed, such as the mechanical forces at navy yards, arsenals, etc., the railway postal service, the rural delivery service and the city delivery service of the post office department. One member of the civil service commission since 1920 has been a woman.

The number of posts entered by competitive examination has been increased by an act of March 3, 1927, bringing the entire bureau of prohibition under the provisions of the civil service law. There are still about 17,000 positions filled by nomination by the president and confirmation by the Senate, besides several thousand excluded by law from the classified civil service. The posi-

tions of deputy collectors of internal revenue and deputy marshals are still regarded as "spoils" for the victors in political contests; and cases of illegal appointment for political reasons still occur and are dealt with by the commission, but the tendency toward a diminution of "spoils" makes steady progress.

When continued lack of eligibles occurs in some of the more specialized positions it becomes necessary to make temporary appointments. This was necessary in 1927 in the case of nurses, dietitians, medical officers and social workers in the Veterans' Bureau. Temporary appointments are also made for laborers and mechanics in the various field branches of the War department and for Christmas-holiday workers in the Post Office department. Appointments for special field activities carried on only in the summer are made in many of the departments.

An act of Congress of July 11, 1919, provides that preference be given in appointment to persons honorably discharged from the Army, Navy or Marine Corp, to their widows, or to their wives in case the veteran is disabled. This is done by adding five points to the earned rating of the veteran. In case of those disabled ten points are added.

An effort is being made to have the remaining 15,651 postmasterships still subject to presidential appointment also included in the classified service, in order that the efficiency of the service might be increased and also that these offices might be opened as a career for subordinate employees. Most of the Presidents, including President Coolidge, and many of the Postmaster Generals have recommended the change.

SUPPLEMENTARY INFORMATION AND BIBLIOGRAPHY.—For fuller information upon the details of the present workings of the merit system in the Federal service, recourse should be had to the annual reports and other publications of the U.S. civil service commission, which are to be found in the public libraries in all the principal cities in the United States, or which may be had free of charge upon application to the commission. Examinations are announced by means of special bulletins which are posted in Federal buildings throughout the country and are given wide publicity through the press and otherwise. The annual reports of the commission contain full statistics of the results of its work, together with comprehensive statements as to the difficulties encountered in enforcing the law, and the means used to overcome them. In the 15th report, p. 443-485, will be found a very valuable historical compilation from original sources, upon the "practice of the presidents in appointments and removals in the executive service, from 1789 to 1883." In the same report, p. 511-517, is a somewhat comprehensive bibliography of "civil service" in periodical literature in the 19th century, brought down to the end of 1898, see also 22nd and 27th reports.

The statutes and presidential rules affecting the civil service are printed in the report of the civil service commission for 1926 and also in a separate publication which is kept current. The chief new statutes and rules since the war are as follows: the retirement act, May 22, 1920; the classification act, March 4, 1923; a presidential order, March 3, 1923, setting forth amended preferences to veterans under an act of July 11, 1919.

CIVITA CASTELLANA (anc. *Falerii*, q.v.), a town and episcopal see of the province of Viterbo, 45m. by rail from the City of Rome (the station is 5m. N.E. of the town) and 32m. by electric tramway, following the Via Flaminia; the tramway goes on to Viterbo, a distance of 28m. north-west. The cathedral of S. Maria possesses a fine portico, erected in 1210 by Laurentius Romanus, his son, Jacobus, and his grandson, Cosmas, in the Cosmatesque style, with ancient columns and mosaic decorations. The interior was modernized in the 18th century. The citadel was erected by Pope Alexander VI. from the designs of Antonio da Sangallo the elder, and enlarged by Julius II. and Leo X. Mt. Soracte lies about 6m. to the south-east.

CIVITAVECCHIA, a seaport town and episcopal see of Italy, province of Rome, 50m. N.W. by rail and 35m. direct from the city of Rome. Pop. (1921) 19,569 (town), 23,314 (com-

muné). It is the ancient *Centum Cellae*, founded by Trajan. Interesting descriptions of it are given by Pliny the Younger and Rutilius. The modern harbour works rest on the ancient foundations, and near it was the cemetery of detachments of the fleets of Misenum and Ravenna. It was a strong populous place in the 6th century, but the Saracens destroyed it in 812. Leo IV. built a new city for the refugees 8m. N.N.E. of Civitavecchia, where may be seen ruins of walls and streets and an inscription, that must have stood over a gate, recording its foundation. The people returned to the old town (whence the name Civitavecchia) in 889, but the new one continued as the castle of Cencelle until the 15th century. In 1508 Pope Julius II. began the construction of the castle from the designs of Bramante, Michelangelo being responsible for the addition of the central tower. Under it lies a Roman house, possibly the port admiral's quarters. Pius IV. added a convict prison. The arsenal was built by Alexander VII. and designed by Bernini. Civitavecchia was the chief port of the Papal State and has still a considerable trade. There are cement factories in the town, which will be considerably increased by the new electric railway to Orte, by which Terni (*q.v.*) is readily accessible. In 1926 ships to the number of 2,285, a total tonnage of 2,041,637, entered and cleared the port, and 789,921 tons of merchandise were imported (chiefly coal and cereals) and exported (chiefly salt) from the saltworks of Porto Clementino, south-west of Tarquinia. There is a thermal establishment in the town, and 3m. N.E. were the *Aquae Tauri*, warm springs; considerable remains of the Roman baths of the time of Trajan are still preserved there. About one mile west of these are hot springs (the *Ficoncella*), also known in Roman times. Five miles down the coast is the summer resort of S. Marinella, which has grown up in the last 20 years and forms a part of the commune of Civitavecchia.

CLACKMANNAN, county town and parish, Clackmannanshire, Scotland. Pop. (1931) 2,585. It lies near the north bank of the Forth, 2 m. east of Alloa, with two stations on the L.N.E.R. Clackmannan Tower is now a picturesque ruin, but at one time was the seat of a lineal descendant of the Bruce family. The old market cross still exists, and close to it stands the stone that gives the town its name (Gaelic, *clach*, stone; Manann, the name of the district). About 1 m. to the south-east is Kennet House, the seat of Lord Balfour of Burleigh, another member of the Bruce family. Coal is mined in the neighbourhood of Clackmannan, which, however, lost its industrial importance to Alloa (*q.v.*).

CLACKMANNANSHIRE, the smallest county in Scotland, bounded south-west by the Forth, west by Stirlingshire, north-north-east and north-west by Perthshire, and east by Fifeshire. It has an area (excluding water) of 34,927 acres. An elevated ridge starting on the west, runs through the middle of the county, widening gradually till it reaches the eastern boundary, and skirting the alluvial or carse lands in the valleys of the Forth and Devon. Still farther north are the Ochil hills, which reach a height of 2,363 ft., a volcanic range of the Old Red Sandstone period, consisting mainly of basalts and andesites. A fault along their southern base brings down the Carboniferous strata, which occupy the southern part of the county. The rivers of importance are the Devon and the Black or South Devon. The first, noted in the upper parts for its scenery and trout-fishing, runs through the county near the base of the Ochils, and falls into the Forth at the village of Cambus, after a winding course of 33 m., although as the crow flies its source is only 5½ miles distant. The Black Devon, rising in the Cleish Hills, flows westwards in a direction nearly parallel to that of the Devon, and falls into the Forth near Clackmannan. It supplies power to mills and collieries; and its whole course is over the Carboniferous strata. The Forth is navigable as far as it forms the boundary of the county. The only lake is Gartmorn which has been dammed in order to furnish water to Alloa and power to mills.

Industries.—The soil is generally productive and well cultivated, though the greater part of the high ground between the carse lands on the Forth and the vale of Devon at the base of the Ochils on the north consists of inferior soils, often lying upon an impervious clay. Oats are the chief crop. The Ochils afford excel-

lent sheep pasture. There is a small tract of moorland in the east, called the Forest, bounded on its northern margin by the Black Devon. Copper, silver, lead and other minerals have been discovered in small quantity in the Ochils, between Alva and Dollar. The Carboniferous strata belong mainly to the coal-measures, forming a northern continuation of the Lanarkshire basin and including a number of valuable coal-seams. Fire-clay, sandstone, and igneous rock are also worked. Coal is mined at Sauchie, Coalsnaughton, Devonside, Clackmannan and other pits. The spinning-mills at Alloa and Clackmannan are active, Alloa yarns and fingering being famous; and woollen goods are largely manufactured at Alva, Clackmannan and Tillicoultry. Distilleries and breweries have a large export business. Minor trades include glass-blowing, coopering, iron-founding, ship-building and paper-making. Mentsrie near Alloa has a large furniture factory. The London and North Eastern railway serves the whole county, while the London, Midland and Scottish has access to Alloa.

Population and Government.—The population was 32,543 in 1921 and 31,947 in 1931, when 156 persons spoke Gaelic and English. The county, with part of Stirling, returns one member to parliament. Clackmannan (pop. 2,585) is the county town, but Alloa (13,322), Alva (3,820), and Tillicoultry (2,953) take precedence in population and trade. Clackmannan forms a sheriffdom with Stirling and Dumbarton shires, and a sheriff-substitute sits at Alloa. There are an exceptionally well-equipped secondary school in Alloa and a well-known academy at Dollar.

CLACTON-ON-SEA, a watering-place in East Essex, England; 7½m. E.N.E. from London by a branch from Colchester of the L.N.E.R. Pop. of urban district (1931) 15,851. Clay cliffs of slight altitude rise from the sandy beach and face south-eastward. In the neighbourhood, however, marshes fringe the shore. The church of Great Clacton, at the village 1½m. inland, is of Norman and later date. It is an important watering-place for London and the suburbs, with convalescent homes and sanatoria.

CLADEL, LÉON (1835–1892), French novelist, was born at Montauban (Tarn-et-Garonne) on March 13, 1835. He made a reputation by his first book, *Les Martyrs ridicules* (1862), a novel for which Charles Baudelaire, whose literary disciple Cladel was, wrote a preface. His best novels are realistic pictures of peasant life in his native district of Quercy. They include: *Le Nommé Quauel* (1868), *Le Bouscassie* (1869), *Les Va-nu-pieds* (1873), a volume of short stories, and *N'a qu'un œil* (1882). He died at Sèvres on July 20, 1892.

See *La Vie de Léon Cladel* (1905), by his daughter Judith Cladel, containing also an article on Cladel by Edmond Picard.

CLAIRAUT (or CLAIRAUT), ALEXIS CLAUDE (1713–1765), French mathematician, was born on May 7 or 13, 1713, at Paris. Under the tuition of his father, a teacher of mathematics, he made such progress that at twelve years of age he read before the French Academy an account of the properties of four curves which he had discovered. His *Recherches sur les courbes à double courbure*, finished in 1729 and published 1731, procured his admission into the Academy of Sciences, although he was still below the legal age. In 1736, with P. L. Maupertuis, he went on the expedition to Lapland, for the purpose of estimating a degree of the meridian; and in 1743 he published his treatise *Théorie de la figure de la terre*, in which he promulgated the theorem known as "Clairaut's theorem," which connects the gravity at points on the surface of a rotating ellipsoid with the compression and the centrifugal force at the equator (see EARTH, FIGURE OF THE). In 1750 he gained the prize of the St. Petersburg Academy for his essay *Théorie de la lune*; and in 1759 he calculated the perihelion of Halley's comet. He also detected singular solutions in differential equations of the first order, and of the second and higher degrees. Clairaut died at Paris on May 17, 1765.

CLAIRON, LA (1723–1803), French actress, whose real name was CLAUDE LERIS, was born at Condé sur l'Escaut, Hainaut, on Jan. 25, 1723, the natural daughter of an army sergeant. In 1736 she made her first stage appearance at the Comédie Italienne, in a small part in Marivaux's *Ile des esclaves*. After several years in the provinces she returned to Paris. Her life, meanwhile,

had been decidedly irregular, even if not to the degree indicated by the libellous pamphlet *Histoire de la demoiselle Cronel, dite Frétilon, actrice de la Comédie de Rouen, écrite par elle-même* (The Hague, 1746), or to be inferred from the disingenuousness of her own *Mémoires d'Hippolyte Clairon* (1798); and she had great difficulty in obtaining an order to make her début at the Comédie Française for which she had the courage to select the title-rôle of *Phèdre* (1743). During her 22 years at this theatre, dividing the honours with her rival Mlle. Dumesnil, she filled many of the classical rôles of tragedy, and created a great number of parts in the plays of Voltaire, Marmontel, Saurin, de Belloy and others. She retired in 1766 and trained pupils for the stage, among them Mlle. Raucourt. Goldsmith called Mlle. Clairon, "the most perfect female figure I have ever seen on any stage" (*The Bee*, 2nd No.); and Garrick, while recognizing her unwillingness or inability to make use of the inspiration of the instant, admitted that "she has everything that art and a good understanding with great natural spirit can give her."

CLAIRTON, a city of Allegheny county, Pennsylvania, U.S.A., on the Monongahela river, 20m. S.E. of Pittsburgh; served by the Pennsylvania, the Pittsburgh and West Virginia and the Union railways. It was formed in 1922 by the consolidation of the boroughs of Clairton, North Clairton and Wilson, which in 1920 had a combined population of 10,777. The city's population in 1930 was 15,291 by the Federal census, and the assessed valuation of property was about \$26,000,000. Clairton has important manufactures of structural iron, steel, boiler tubes, river boats and barges and an immense by-product coke plant (22 batteries, 1,484 ovens) which uses 8,000,000 tons of coal in a year.

CLAIRVAUX, a village of north-eastern France, in the department of Aube, 40 m. E.S.E. of Troyes. Clairvaux (*Clara Vallis*) is situated in the valley of the Aube on the eastern border of the forest of Clairvaux. Its abbey founded in 1115 by St. Bernard became the centre of the Cistercian order. The buildings (*see ABBEY*) belong for the most part to the 18th century, but there is a large storehouse which dates from the 12th century.

CLAIRVOYANCE, a word used with several different meanings in spiritualism and psychical research. Sometimes it is used to denote transcendental vision of beings on another plane of existence, while F. W. H. Myers, in the glossary to his *Human Personality*, defines it as "the faculty or act of perceiving as though visually, with some coincidental truth, some distant scene." It is now, however, often used as a term complementary to and exclusive of telepathy (*q.v.*), to denote all forms of supernormal cognition where the percipient's knowledge is not derived from another mind, whether or not the knowledge is communicated as a visual impression. It is in this last sense that the word is used in the article on **PSYCHICAL RESEARCH** (*q.v.*).

CLAM, the name applied to many bivalve molluscs (*see LAMELLIBRANCHIA*) from the vice-like firmness with which the shell closes. In Scotland the name is usually applied to the scallop (*q.v.*), in England to species of *Mya* and *Macra* especially the gaper, *Mya truncata*. In the United States the name has a wider use, but most commonly denotes *Venus mercenaria*, the quahog or hard clam, and *Mya arenaria*, the soft clam, both of which are of great importance as food, besides being extensively used by fishermen as bait. The hard clam is allied to the cockle (*q.v.*) and has a heavy shell which was used as shell-money (*see WAMPUM*) by the Indians. It is found in one to six fathoms of water off the Atlantic coast of North America from Florida to Cape Cod and also off New Brunswick. It is obtained by raking the bottom. Young specimens, known as "little necks," are sold in large numbers in New York. The soft clam is found mainly between the tide-marks and has a thin shell and long siphons. "Clam bakes," where clams are placed on heated stones with potatoes and other food, the whole being covered with sea-weed and left to cook, make a popular picnic in America. Atlantic clams have been transplanted to the Pacific coast of North America with great success, though there are several indigenous species there which are also known by this name. It is an interesting point that while both *Mya* and *Mytilus* (the sea mussel, *q.v.*) occur on both sides of the Atlantic, the former is not eaten in Europe, the latter

not in America; furthermore, in the prehistoric "kitchen-middens," remains of *Mytilus* are found in Europe and of *Mya* in America, but not vice versa. The American "fresh-water clams" are fresh-water mussels (*Unionidae*).

Of other species to which the name clam is applied, the most noteworthy are the bear's paw clam (*Hippopus maculatus*) of the Indian ocean, with a beautiful ridged white shell, marked with spots of purplish-red; and the giant clam (*Tridacna gigas*) of the West Indies, the largest of all lamellibranchs; the actual animal may weigh 20 lb. and the shell nearly $\frac{1}{4}$ of a ton.

CLAMECY, a town of central France, capital of an arrondissement in the department of Nièvre, at the confluence of the Yonne and Beuvron and on the Canal du Nivernais, 36 m. N.N.E. of Nevers. Pop. (1926) 4,509. In the early middle ages Clamecy belonged to the abbey of St. Julian at Auxerre; in the 11th century it passed to the counts of Nevers. After the capture of Jerusalem by Saladin in 1188, Clamecy became the seat of the bishops of Bethlehem, who till the Revolution resided in the hospital of Panthenor, bequeathed by William IV., count of Nevers. The town figured in the *coup d'état* of 1851.

The church of St. Martin, dates chiefly from the 13th, 14th and 15th centuries. The tower and façade are of the 16th century. The *chevet*, surrounded by an aisle, is rectangular—a feature found in few French churches. Of the old castle of the counts of Nevers, vaulted cellars alone remain. There are a sub-prefecture and tribunals of first instance and of commerce. The town has fulling and flour mills, with a small leather and chemical trade. Wine and cattle and timber are important.

CLAN, a social group of fundamental importance in the social structure of many primitive societies.

The most important character of the clan is its exogamy—*i.e.*, marriage within the clan is forbidden, and regarded as incest (*see EXOGAMY*). This tabu applies even to persons between whom no genealogical relationship can be traced. Although for scientific purposes the clan is defined as an exogamous group, the term is frequently used in popular literature for groups that are not exogamous, such as the tribe; and that rather vague entity, the Scottish clan, though sharing some of the characters of the clan, is not an exogamous group, whatever it may once have been. Partly for these reasons, American writers use the term "sib" instead of "clan."

The clan is a unilateral group; that is to say, membership of the clan is determined, either by descent through the mother ("matrilineal clan," "mother-sib," or "clan," as it has been variously named) or by descent through the father ("patrilineal clan," "father-sib," or "gens"). This does not mean, however, that descent from some original ancestor can be traced, though belief in such descent is usually present. The clan, therefore, has only a slight resemblance to the family (*q.v.*) which necessarily contains members of more than one clan, though it is possible that the clan has evolved from the family by emphasis of one line of descent.

Although the clan is not a kinship-group—for kinship implies not only relationship by direct descent, but the ability to trace it genealogically—nevertheless, it is common for members of a clan to address one another by means of relationship-terms used between close kin, and this carries with it the same sort of social relations as we find between close kin, though in less degree. This is a natural result of the classificatory system of relationships which is frequently associated with it, but even in the absence of this system it is common for distant members of a clan to claim brotherhood with one another, and to feel that kind of solidarity found in the case of the family. This solidarity is a most striking character of the clan. The individual identifies himself with his clan in a peculiarly intimate way, so that clan-responsibility for the action of individual members is common. This unity of the clan frequently extends into the political and economic sphere.

The unity of the clan is frequently emphasized by the possession of a totem (*see TOTEMISM*). Where clans are much interspersed and widely diffused, clan-identity may thus be established and maintained, which even the classificatory system of relationships need not reveal. It is doubtful whether habitation

of a common territory is ever the common tie uniting members of a clan, but localized clans do sometimes occur, though it is probable that in such cases the localization is secondary, and the common tie is belief in common descent.

Not uncommon is a grouping of clans into wider units, the simplest form of this being a dual organization (*q.v.*) in which the clans are grouped into two exogamous divisions. It is also not uncommon for there to be a division of function between the clans of a tribe, occasionally economic, *e.g.*, in India, but more usually political or religious, *e.g.*, in some African kingdoms.

BIBLIOGRAPHY.—The clan is defined and discussed in general books on Sociology, such as W. H. R. Rivers, *Social Organization* (1924), R. H. Lowie, *Primitive Society* (1921), and E. Westermarck, *History of Human Marriage*, vol. ii. (1921). (W. E. A.)

CLANRICARDE, ULICK DE BURGH (BOURKE or BURKE), MARQUESS OF (1604–1657 or 1658), son of Richard, 4th earl of Clanricarde, created in 1628 earl of St. Albans, and of Frances, daughter and heir of Sir Francis Walsingham, and widow of Sir Philip Sidney and of Robert Devereux, earl of Essex, was born in 1604. He was summoned to the House of Lords as Lord Burgh in 1628, and succeeded his father as 5th earl in 1635. He sat in the Short Parliament of 1640 and attended Charles I. in the Scottish expedition. On the outbreak of the Irish rebellion Clanricarde had powerful inducements for joining the Irish—the ancient greatness and independence of his family, his devotion to the Roman Catholic Church, and strongest of all, the ungrateful treatment meted out by Charles I. and Wentworth to his father, one of Elizabeth's most staunch adherents in Ireland, whose lands were appropriated by the crown and whose death, it was popularly asserted, was hastened by the harshness of the lord-lieutenant. Nevertheless at the crisis his loyalty never wavered. Alone of the Irish Roman Catholic nobility to declare for the king, he returned to Ireland, took up his residence at Portumna, kept Galway, of which he was governor, neutral, and took measures for the defence of the county and for the relief of the Protestants, making "his house and towns a refuge, nay, even a hospital for the distressed English." In 1643 he was one of the commissioners appointed by the king to confer with the Irish confederates, and urged the wisdom of a cessation of hostilities in a document which he publicly distributed. He was appointed commander of the English forces in Connaught in 1644, and in 1646 was created a marquess and a privy councillor. He supported the same year the treaty between Charles I. and the confederates, and endeavoured after its failure to persuade Preston, the general of the Irish, to agree to a peace; but the latter, being advised by Rinuccini, the papal nuncio, refused in December. Together with Ormonde, Clanricarde opposed the nuncio's policy; and the royalist inhabitants of Galway having through the latter's influence rejected the cessation of hostilities, arranged with Lord Inchiquin in 1648, he besieged the town and compelled its acquiescence. In 1649 he reduced Sligo. On Ormonde's departure in Dec. 1650 Clanricarde was appointed deputy lord-lieutenant, but he was not trusted by the Roman Catholics, and was unable to stem the tide of the parliamentary successes. In 1651 he opposed the offer of Charles, duke of Lorraine, to supply money and aid on condition of being acknowledged "Protector" of the kingdom. In May 1652 Galway surrendered to the parliament, and in June Clanricarde signed articles with the parliamentary commissioners which allowed his departure from Ireland. In August he was excepted from pardon for life and estate, but by permits, renewed from time to time by the council, he was enabled to remain in England for the rest of his life, and in 1653 £500 a year was settled upon him by the Council of State in consideration of the protection which he had given to the Protestants in Ireland at the time of the rebellion. He died at Somerhill in Kent in 1657 or 1658 and was buried at Tunbridge.

The "great earl," as he was called, supported Ormonde in his desire to unite the English royalists with the more moderate Roman Catholics on the basis of religious toleration under the authority of the sovereign, against the papal scheme advocated by Rinuccini, and in opposition to the parliamentary and Puritan policy. There is no reason to doubt Clarendon's opinion of him

as "a person of unquestionable fidelity . . . and of the most eminent constancy to the Roman Catholic religion of any man in the three kingdoms," or the verdict of Hallam, who describes him "as perhaps the most unsullied character in the annals of Ireland." (See also CLANRICARDE, EARL OF.)

Gardiner's *Hist. of the Civil War and of the Commonwealth*; *Cal. of State Papers, Irish*, esp. *Introd.* 1633–47 and *Domestic*; *Hist. MSS. Comm.*, *MSS. of Marq. of Ormonde and Earl of Egmont*. (P. C. Y.)

CLANRICARDE, EARL OF, Irish title, held, since 1916, by the marquess of Sligo. In 1543, Ulick (d. 1544) (*q.v.*), chief of the "MacWilliam Eighter" branch of the De Burgh family (*q.v.*), surrendered his territory lying in the neighbourhood of Galway to Henry VIII., receiving it back to hold, by English custom, as earl of Clanricarde and Lord Dunkellin. Richard, the 4th earl (1601–35) who fought on the English side in O'Neill's rebellion, obtained the English earldom of St. Albans in 1628, his son, Ulick (*q.v.*), receiving the Irish marquessate of Clanricarde in 1646; but at the death of the latter, without heirs, the English honours and the marquessate expired, and the Irish earldom went to his cousin, Richard, 6th earl (1657–66). The 9th earl, John, forfeited his estates, for his support of James II. but they were restored to him in 1702, and his great-grandson, the 12th earl, was created marquess in 1789. He left no son, but the marquessate was again revived in 1825, for Ulick, 14th earl, who was lord privy seal, and was created Baron Somerhill, in the United Kingdom, in 1826. On the death of Hubert, George, 2nd marquess (1832–1916) Ulick's son, all his honours became extinct, except the earldom of Clanricarde (c. 1800), which passed to his kinsman, the marquess of Sligo.

CLANRICARDE, ULICK DE BURGH (BOURKE or BURKE), 1ST EARL OF (d. 1544), styled MacWilliam and Ne-gan or Na-gCeann (*i.e.*, "of the Heads," "having made a mound of the heads of men slain in battle which he covered up with earth"), was the son of Richard or Rickard de Burgh, lord of Clanricarde, by a daughter of Madden of Portumna, and grandson of Ulick de Burgh, lord of Clanricarde (1467–87), the collateral heir male of the earls of Ulster. Ulick de Burgh succeeded to the headship of his clan, exercised a quasi-royal authority and held vast estates in county Galway, in Connaught, including Loughry, Dunkellin, Kiltartan (Hilltaraght) and Athenry, as well as Clare and Leitrim. In March 1541, he wrote to Henry VIII., placing himself and his estates in the king's hands. The same year he was present at Dublin, when the act was passed making Henry VIII. king of Ireland. In 1543, in company with other Irish chiefs, he visited the king at Greenwich, made full submission, undertook to introduce English manners and abandon Irish names, received a regrant of the greater part of his estates with the addition of other lands, was confirmed in the captainship and rule of Clanricarde, and was created on the 1st July 1543 earl of Clanricarde and baron of Dunkellin in the peerage of Ireland, with unusual ceremony. "The making of McWilliam earl of Clanricarde made all the country during his time quiet and obedient," states Lord Chancellor Cusack in his review of the state of Ireland in 1553. He did not live long, however, to enjoy his new English dignities, but died shortly after returning to Ireland about March 1544.

See R. Bagwell, *Ireland under the Tudors*, vol. i.; Gairdner's *Letters and Papers of Henry VIII.*

CLANVOWE, SIR THOMAS, English 14th century poet, author of *The Cuckoo and the Nightingale*, long attributed to Chaucer. Little is known of Clanvowe, whose name is last mentioned in 1404. He figured at the courts of Richard II. and Henry IV., and was one of the 20 knights who accompanied John Beaufort to Barbary in 1390. His name was discovered on the best of the mss. by Professor Skeat in editing *The Book of Cupid, God of Love, or the Cuckoo and the Nightingale*.

The historic and literary importance of *The Cuckoo and the Nightingale* is great. It is the work of a poet who had studied the prosody of Chaucer with more intelligent care than either Oocleve or Lydgate, and who therefore forms an important link between the 14th and 15th centuries in English poetry. Clanvowe writes

with a surprising delicacy and sweetness, in a five-line measure almost peculiar to himself. Professor Skeat points out a unique characteristic of Clanvowe's versification, namely, the unprecedented freedom with which he employs the suffix of the final -e, and rather avoids than seeks elision. *The Cuckoo and the Nightingale* was imitated by Milton in his sonnet to the nightingale, and was rewritten in modern English by Wordsworth.

See also a critical edition of the *Boke of Cupide* by Dr. Erich Vollmer (Berlin, 1898).

CLAPARÈDE, JEAN LOUIS RENÉ ANTOINE ÉDOUARD (1832-1870), Swiss naturalist, was born at Geneva on April 24, 1832. He belonged to a French family, some members of which had taken refuge in that city after the revocation of the Edict of Nantes. In 1852 he began to study medicine and natural science at Berlin, where he was greatly influenced by J. Müller, who was then working on the Echinoderms. The latter part of his stay at Berlin he devoted, along with J. Lachmann, to the study of the Infusoria and Rhizopods. In 1862 he was chosen professor of comparative anatomy at Geneva. He died at Siena on May 31, 1870. His *Recherches sur la structure des annélides sédentaires* was published posthumously in 1873.

CLAPPERTON, HUGH (1788-1827), Scottish traveller in central Africa, was born at Annan, Dumfriesshire, and after some years in the merchant service was impressed into the navy. In 1817 he returned home with the grade of lieutenant, and in 1820 accompanied Oudney and Denham in the Government expedition to Bornu. From Bornu they set out to explore the Niger country. After Oudney's death at Murmur (Jan. 1824) Clapperton proceeded along to Kano and Sokoto, returning by way of Zatia and Katsena to Kuka, where he met Denham. An account of the travels was published in 1826 under the title of *Narrative of Travels and Discoveries in Northern and Central Africa in the years 1822-1824*.

Immediately after his return Clapperton was raised to the rank of commander, and sent out with another expedition to Africa. He landed at Badagry in the Bight of Benin, and started overland for the Niger on Dec. 7, 1825, having with him his servant Richard Lander (*q.v.*), Captain Pearce, R.N., and Dr. Morrison, navy surgeon and naturalist. Before the month was out Pearce and Morrison were dead of fever. Clapperton continued his journey, and, passing through the Yoruba country, in Jan. 1826 he crossed the Niger at Bussa, where Mungo Park had died 20 years before. In July he arrived at Kano. Thence he went to Sokoto, intending afterwards to go to Bornu. The sultan, however, detained him, and he died of dysentery near Sokoto on April 13, 1827. Clapperton was the first European to make known from personal observation the semi-civilized Hausa countries, which he visited soon after the establishment of the Sokoto empire by the Fula.

In 1829 appeared the *Journal of a Second Expedition into the Interior of Africa*, etc., by the late Commander Clapperton, with a biographical sketch of the explorer by Lieut.-Col. S. Clapperton. Lander, who had brought back the journal of his master, also published *Records of Captain Clapperton's Last Expedition to Africa . . . with the subsequent Adventures of the Author* (2 vols. 1830).

CLIQUE, an organized body of professional applauders in the French theatres (Fr. *claque*, to clap the hands). The hiring of persons to applaud dramatic performances was common in classical times, and the emperor Nero, when he acted, had his performance greeted by a chorus of 5,000 soldiers. Jean Daurat, the 16th century French poet, bought up a number of tickets for a performance of one of his plays and distributed them gratuitously to those who promised publicly to express their approbation. In 1820 an office was opened in Paris for the supply of *claqueurs*, and any number of them could be ordered in a way similar to the ordering of "extras" for a motion picture production of the present day. These people were usually under a *chef de clique*, whose duty it was to judge where their efforts were needed and to start the applause. The *commissaires* were scattered among the audience and called the attention of their neighbours to the good points of the play. The *rieurs* were those who laughed loudly at

the jokes. The *pleureurs*, generally women, feigned tears, by holding their handkerchiefs to their eyes. The *chatouilleurs* kept the audience in a good humour, while the *bisseurs* simply clapped their hands and cried *bis! bis!* to secure encores.

CLARA, SAINT (1194-1253), foundress of the Franciscan nuns, was born of a knightly family in Assisi in 1194. At eighteen she was so impressed by a sermon of St. Francis that she was filled with the desire to devote herself to the kind of life he was leading. She obtained an interview with him, and to test her resolution he told her to dress in penitential sackcloth and beg alms for the poor in the streets of Assisi. Clara readily did this, and Francis, satisfied as to her vocation, told her to come to the Portiuncula arrayed as a bride. The friars met her with lighted candles, and at the foot of the altar Francis shore off her hair, received her vows of poverty, chastity and obedience, and invested her with the Franciscan habit, 1212. He placed her for a couple of years in a Benedictine convent in Assisi until the convent at St. Damian's, close to the town, was ready. Her two younger sisters, and, after her father's death, her mother and many others joined her, and the Franciscan nuns spread widely and rapidly (*see* CLARES, POOR). The relations of friendship and sympathy between St. Clara and St. Francis were very close, and there can be no doubt that she was one of the truest heirs of Francis's inmost spirit. After his death Clara threw herself wholly on the side of those who opposed mitigations in the rule and manner of life, and she was one of the chief upholders of St. Francis's primitive idea of poverty (*see* FRANCISCANS). She was the close friend of Brother Leo and the other "Companions of St. Francis," and they assisted at her death. For 40 years she was abbess at St. Damian's, and the great endeavour of her life was that the rule of the nuns should be purged of the foreign elements that had been introduced, and should become wholly conformable to St. Francis's spirit. She lived just long enough to witness the fulfilment of her great wish, a rule such as she desired being approved by the pope two days before her death on Aug. 11, 1253.

The sources for her life are to be found in the Bollandist *Acta Sanctorum* on Aug. 11, and sketches in such *Lives of the Saints* as Alban Butler's. *See* also Wetzer und Welte, *Kirchenlexicon* (2nd ed.), art. "Clara." (E. C. B.)

CLARE, the name of a famous English family. The ancestor of this historic house, "which played," in Freeman's words, "so great a part alike in England, Wales and Ireland," was Count Godfrey, eldest of the illegitimate sons of Richard the Fearless, duke of Normandy. His son, Count Gilbert of Brionne, had two sons, Richard, lord of Bienfaite and Orbec, and Baldwin, lord of Le Sap and Meulles, both of whom accompanied William the Conqueror to England. Baldwin, known as "De Meulles" or "of Exeter," received the hereditary shrievalty of Devon with great estates in the West Country, and left three sons, William, Robert and Richard, of whom the first and last were in turn sheriffs of Devon. Richard, known as "de Bienfaite," or "of Tunbridge," or "of Clare," was the founder of the house of Clare.

Richard derived his English appellation from his strongholds at Tunbridge and at Clare, at both of which his castle-mounds still remain. The latter, on the borders of Essex and Suffolk, was the head of his great "honour" which lay chiefly in the eastern counties. Appointed joint justiciar in the king's absence abroad, he took a leading part in suppressing the revolt of 1075. By his wife, Rohese, daughter of Walter Giffard, through whom great Giffard estates afterwards came to his house, he left five sons and two daughters. Roger was his heir in Normandy, Walter founded Tintern Abbey, Richard was a monk, and Robert, receiving the forfeited fief of the Baynards in the eastern counties, founded, through his son Walter, the house of FitzWalter (extinct 1432), of whom the most famous was Robert FitzWalter, the leader of the barons against King John. Of this house, spoken of by Jordan Fantosme as "Clarreaus," the Daventrys of Daventry (extinct 1380) and Fawleys of Fawley (extinct 1392) were cadets. One of Richard's two daughters married the famous Walter Tirel.

Gilbert, Richard's heir in England, held his castle of Tunbridge against William Rufus, but was wounded and captured. Under Henry I., who favoured the Clares, he obtained a grant of Cardi-

gan and carried his arms into Wales. Dying about 1115, he left four sons, of whom Gilbert, the second, inherited Chepstow, with Nether-Gwent, from his uncle, Walter, the founder of Tintern, and was created earl of Pembroke by Stephen about 1138; he was father of Richard Strongbow, earl of Pembroke (q.v.). The youngest son Baldwin fought for Stephen at the battle of Lincoln (1141) and founded the priories of Bourne and Deeping on lands acquired with his wife. The eldest son Richard, who was slain by the Welsh on his way to Cardigan in 1135 or 1136, left two sons, Gilbert and Roger, of whom Gilbert was created earl of Hertfordshire by Stephen.

It was probably because he and the Clares had no interests in Hertfordshire that they were loosely and usually styled the earls of (de) Clare. Dying in 1152, Gilbert was succeeded by his brother Roger, of whom Fitz-Stephen observes that "nearly all the nobles of England were related to the earl of Clare, whose sister, the most beautiful woman in England, had long been desired by the king" (Henry II.). He was constantly fighting the Welsh for his family possessions in Wales and quarrelled with Becket over Tunbridge castle. In 1173 or 1174 he was succeeded by his son Richard as third earl, whose marriage with Amicia, daughter and co-heir of William, earl of Gloucester, was destined to raise the fortunes of his house to their highest point. He and his son Gilbert were among the "barons of the Charter." Gilbert, who became fourth earl in 1217, obtained also, early in 1218, the earldom of Gloucester, with its great territorial "Honour," and the lordship of Glamorgan, in right of his mother; "from this time the house of Clare became the acknowledged head of the baronage." Gilbert had also inherited through his father his grandmother's "Honour of St. Hilary" and a moiety of the Giffard fief; but the vast possessions of his house were still further swollen by his marriage with a daughter of William (Marshal), earl of Pembroke, through whom his son Richard succeeded in 1245 to a fifth of the Marshall lands including the Kilkenny estates in Ireland. Richard's successor, Gilbert, the "Red" earl, died in 1295, the most powerful subject in the kingdom.

On his death his earldoms seem to have been somewhat mysteriously deemed to have passed to his widow Joan, daughter of Edward I.; for her second husband, Ralph de Monthermer, was summoned to parliament in right of them from 1299 to 1306. After her death, however, in 1307, Earl Gilbert's son and namesake was summoned in 1308 as earl of Gloucester and Hertford, though only sixteen. A nephew of Edward II. and brother-in-law of Gaveston, he played a somewhat wavering part in the struggle between the king and the barons. Guardian of the realm in 1311 and regent in 1313, he fell at Bannockburn.

The earl was the last of his mighty line, and his vast possessions in England (in over 20 counties), Wales and Ireland fell to his three sisters, of whom Elizabeth, the youngest, wife of John de Burgh, obtained the "Honour of Clare" and transmitted it to her son William de Burgh, 3rd earl of Ulster, whose daughter brought it to Lionel, son of King Edward III., who was thereupon created Duke of Clarence, a title associated ever since with the royal house. The "Honour of Clare," vested in the crown, still preserves a separate existence, with a court and steward of its own.

Clare College, Cambridge, derived its name from the above Elizabeth, "Lady of Clare," who founded it as Clare Hall in 1347.

Clare County in Ireland derived its name from the family, though whether from Richard Strongbow, or from Thomas de Clare, a younger son, who had a grant of Thomond in 1276, has been deemed doubtful.

Clarenceux King of Arms, an officer of the Heralds' college, derives his style, through Clarence, from Clare.

CLARE, JOHN (1793-1864), English poet, known as "the Northamptonshire Peasant Poet," was born at Helpstone, near

Peterborough. He was the son of a farm-labourer, and when he was 12 or 13 began to work on a farm himself, attending a school in the evenings. At 16 he fell deeply in love with Mary Joyce, the daughter of a prosperous farmer, who forbade her to meet her lover. Clare never forgot this first love, and in his periods of insanity, long after Mary's death, he used to hold conversations with her, under the delusion that she still lived and was his wife. He tried his hand at many trades, was gardener at Burghley park, enlisted in the militia, and in 1817 worked as a lime-burner; from his last place he was discharged for spending his working hours in distributing copies of a prospectus of a book of his poems, and he was obliged to accept parish relief. The prospectus failed to attract subscribers, but luckily in 1817 a bookseller at Stamford, named Drury, noticed one of Clare's poems, "The Setting Sun," by chance, and befriended the author, introducing him to John Taylor, the publisher of Keats and Shelley. Taylor published Clare's *Poems Descriptive of Rural Life and Scenery* (1820), which attracted great attention, and his *Village Minstrel and other Poems* (1821). The poet was now comparatively prosperous with an annuity of £45. obtained by the patronage of Lord Exeter and other subscribers; but in 1820 he had married Patty Turner, and a growing family made his income inadequate. *The Shepherd's Calendar* (1827) met with little success, and Clare started farm labour again. Worry and overwork made him seriously ill. Earl Fitzwilliam gave him a new cottage and a piece of ground in 1832 but Clare could not settle down; gradually his mind gave way. He was still writing verse, but his last work, the *Rural Muse* (1835), was noticed by "Christopher North" alone. For some time he had shown signs of insanity; and in 1837, in spite of the efforts of his wife to prevent outside interference, he was removed to a private asylum. He seemed happy there, but after a time decided to go home, and set out to walk all the way. Then he was taken to the Northampton general lunatic asylum, where he remained, amusing himself by writing poetry, until his death.

BIBLIOGRAPHY.—The Oxford ed. of his *Poems* (1920), was ed. by Edmund Blunden and Alan Porter; his *Madrigals and Chronicles* by Edmund Blunden (1924). Both these eds. contain biographical introductions. See also F. Martin *The Life of John Clare* (1865); and J. L. Cherry *Life and Remains of John Clare* (1873).

CLARE, JOHN FITZGIBBON, 1ST EARL OF (1749-1802), lord chancellor of Ireland, the second son of John Fitzgibbon, was educated at Trinity college, Dublin, where he was highly distinguished as a classical scholar, and at Christ Church, Oxford, where he graduated in 1770. In 1772 he was called to the Irish bar. In 1778 he entered the Irish House of Commons as member for Dublin university, and at first gave a general support to the popular party led by Henry Grattan (q.v.). He was, however, from the first hostile to that part of Grattan's policy which aimed at removing the disabilities of the Roman Catholics; he endeavoured to impede the Relief bill of 1778 by raising difficulties about its effect on the Act of Settlement. As early as 1780 Fitzgibbon began to separate himself from the popular or national party by opposing Grattan's declaration of the Irish parliament's right to independence. His hostility to the Catholic claims, and his distrust of parliamentary reform as likely to endanger the connection of Ireland with Great Britain, made him a sincere opponent of the purposes which Grattan had in view. Grattan supported the appointment of Fitzgibbon as attorney-general in 1783, and in 1785 the latter highly eulogized Grattan's character and services to the country in a speech in which he condemned Flood's volunteer movement. He also opposed Flood's Reform bill of 1784; and from this time forward he was in fact the leading spirit in the Irish Government, and the stiffest opponent of all concession to popular demands. In 1784 the permanent committee of revolutionary reformers in Dublin, of whom Napper Tandy was the most conspicuous, invited the sheriffs of counties to call meetings for the election of delegates to attend a convention for the discussion of reform; and when the sheriff of the county of Dublin summoned a meeting for this purpose Fitzgibbon procured his imprisonment for contempt of court, and justified this procedure in parliament, though Lord Erskine declared it grossly illegal. In the course of the debates on Pitt's

commercial propositions in 1785, which Fitzgibbon supported in masterly speeches, he referred to Curran in terms which led to a duel between the two lawyers, when Fitzgibbon was accused of a deliberation in aiming at his opponent that was contrary to etiquette. His antagonism to Curran was life-long and bitter, and after he became chancellor his hostility to the famous advocate was said to have driven the latter out of practice. In Jan. 1787 Fitzgibbon introduced a stringent bill for repressing the Whiteboy outrages. His influence with the majority in the Irish parliament defeated Pitt's proposed reform of the tithe system in Ireland, Fitzgibbon refusing even to grant a committee to investigate the subject. On the regency question in 1789 Fitzgibbon, in opposition to Grattan, supported the doctrine of Pitt in a series of powerful speeches which proved him a great constitutional lawyer; he intimated that the choice for Ireland might in certain eventualities rest between complete separation from England and legislative union; and, while he exclaimed as to the latter alternative, "God forbid that I should ever see that day!" he admitted that separation would be the worse evil of the two.

In the same year Lord Lifford resigned the chancellorship, and Fitzgibbon was appointed in his place, being raised to the peerage as Baron Fitzgibbon. His removal to the House of Lords greatly increased his power. "He was," says Lecky, "by far the ablest Irishman who had adopted without restriction the doctrine that the Irish legislature must be maintained in a condition of permanent and unvarying subjection to the English executive." But the English ministry were now embarking on a policy of conciliation in Ireland. The Catholic Relief bill of 1793 was forced on the Irish executive by the cabinet in London, but it passed rapidly and easily through the Irish parliament. Fitzgibbon was opposed to the appointment of Lord Fitzwilliam (*q.v.*) as viceroy in 1795, and was probably the chief influence in procuring his recall; and it was Fitzgibbon who first put it into the head of George III. that the king would violate his coronation oath if he consented to the admission of Catholics to parliament. When Lord Camden, Fitzwilliam's successor in the viceroyalty, arrived in Dublin on March 31, 1795, Fitzgibbon's carriage was violently assaulted by the mob, and he himself was wounded; and in the riots that ensued his house was also attacked. In June 1795 he was created earl of Clare. On the eve of the rebellion he warned the Government to take stringent measures to prevent an outbreak; but he was neither cruel nor immoderate and was inclined to mercy in dealing with individuals. He attempted to save Lord Edward Fitzgerald (*q.v.*) from his fate by giving a friendly warning to his friend, and promising to facilitate his escape from the country. After the rebellion he threw his great influence on the side of clemency.

In Oct. 1798 Lord Clare, who since 1793 had been convinced of the necessity for a legislative union between Great Britain and Ireland, and was equally determined that the union must be unaccompanied by Catholic emancipation crossed to England and pressed his views on Pitt. In 1799 he induced the Irish House of Lords to throw out a bill for providing a permanent endowment Maynooth. On Feb. 10, 1800, Clare in the House of Lords moved the resolution approving the union in a long and powerful speech, in which he reviewed the history of Ireland since the Revolution, attributing the evils of recent years to the independent constitution of 1782, and speaking of Grattan in language of deep personal hatred. He was not aware of the assurance which Cornwallis had been authorized to convey to the Catholics that the union was to pave the way for emancipation, and when he heard of it after the passing of the act he bitterly complained that Pitt and Castlereagh had deceived him. After the union Clare became more violent than ever in his opposition to any policy of concession in Ireland. He died on Jan. 28, 1802.

Lord Clare was the first Irishman since the Revolution to hold the office of lord chancellor of Ireland. As a politician there is no doubt that his bitter and unceasing resistance to reasonable measures of reform did infinite mischief by inflaming the passions of his countrymen, driving them into rebellion, and perpetuating their political and religious divisions.

CLARE, a county in the province of Munster, Ireland, bounded north by Galway Bay and Co. Galway, east by Lough Derg, the river Shannon, and counties Tipperary and Limerick, south by the estuary of the Shannon, and west by the Atlantic Ocean. The area is 852,389 acres. Pop. (1926) 95,028.

In the eastern mountains two masses of Old Red Sandstone with Silurian cores stand out, the more southerly of which, Slieve Bernagh, rises to a height of 1,746 ft. These masses are flanked by Carboniferous limestone which occupies the north and east of the county. The south-west is composed of Millstone Grit and Coal Measures which extend some distance into the interior. There are many lakes in the central lowlands and bogs are frequent on the higher land. In the southern part, along the banks of the Fergus and Shannon, are bands of rich low grounds called corcasses, of various breadth, indenting the land in a great variety of shapes. They are composed of deep rich loam, and are distinguished as the black corcasses, adapted for tillage, and the blue, used more advantageously as meadow land. The coast is rocky, and occasionally bold precipitous cliffs rise to a considerable height. There are numerous bays around the coast but Liscannor Bay provides the only safe anchorage on the Atlantic side. The River Fergus flows into the estuary of the Shannon, the creeks and bays of which render navigation safe in all winds.

The county, especially on the higher areas of the east and north, is very rich in dolmens. There still exist above a hundred fortified castles, mostly small, several of which are inhabited. Rathes or encampments are to be found in every part. They are generally circular, composed either of large stones without mortar or of earth thrown up and surrounded by one or more ditches. The abbeys and other religious houses number more than twenty. Five round towers are to be found in various stages of preservation at Scatterry Island, Drumcliffe, Dysert O'Dea, Kilnaboy and Inniscaltra (Lough Derg). The cathedral of the diocese of Killaloe is at the town of that name.

The county, together with part of the neighbouring district, was anciently called Thomond, that is, North Munster. Settlements were effected by the Danes, and in the 13th century by the Anglo-Normans, but without permanently affecting the possession of the district by its native proprietors. In 1543 Murrough O'Brien submitted to Henry VIII., and received the title of earl of Thomond, on condition of adopting English dress, manners and customs. In 1565 this part of Thomond was added to Connaught, and made one of the six new counties into which that province was divided by Sir Henry Sidney. It was named Clare, the name being traceable either to Richard de Clare (Strongbow), earl of Pembroke, or to his younger brother, Thomas de Clare, who obtained a grant of Thomond from Edward I. in 1276. Towards the close of the reign of Elizabeth, Clare was detached from the government of Connaught and given a separate administration; but it was included with Connaught in Cromwell's schemes and suffered greatly as a result of his policy. At the Restoration it was united to Munster.

Metals and minerals have not been found in sufficient abundance to encourage commercial exploitation. The principal metals are lead, iron and manganese. The Milltown lead mine in the barony of Tulla is probably one of the oldest mines in Ireland and formerly there must have been a very rich deposit. Copper pyrites occurs in several parts of Burren in small quantity. Coal exists in Labasheeda on the right bank of the Shannon, but the few and thin seams are not productive. The nodules of clay-ironstone in the strata that overlie the limestone were mined and smelted down to 1750. Within half a mile of the Milltown lead mine are natural vaulted passages of limestone. The lower limestone of the eastern portion of the county has been found to contain several very large deposits of argentiferous galena. Flags, easily quarried, are procured near Kilrush, and thinner flags near Ennistimon. Slates are

quarried in several places, the best being those of Broadford and Killaloe. Very fine black marble is obtained near Ennis; it takes a high polish, and is free from the white spots with which the black Kilkenny marble is marked.

The soil and surface of the county are in general better adapted for grazing than for tillage. Agriculture is in a backward state, and the acreage shows a decrease even in the principal crops of oats and potatoes. Cattle, sheep, poultry and pigs, however, all receive considerable attention. Owing to the mountainous nature of the county, nearly one-seventh of the total area is quite barren.

There are no extensive manufactures, although flannels and friezes are made for home use, and hosiery of various kinds, chiefly coarse and strong, is made around Ennistimon and other places. There are several fishing stations but the rugged nature of the coast and the rough sea greatly hinder fishermen. Near Pooldoody is the great Burren oyster bed called the Red Bank. Crabs and lobsters are caught in the Bay of Galway. In addition to the Shannon salmon fishery, eels abound in every rivulet, and form an important article of consumption.

The Great Southern railway line from Limerick to Sligo intersects the centre of the county. From Ennis a branch runs to Ennistimon where it turns south and serves such watering-places as Milltown Malbay, Kilkee and Kilrush. Killaloe is the terminus of a railway branch near the site of the Shannon Power Scheme (see Shannon). Clare has 5 members in Dail Eireann.

CLAREMONT, a town of Sullivan county, New Hampshire, U.S.A., in the western part of the State, on the Connecticut river, at the mouth of Sugar river; served by the Boston and Maine railroad. The area is 6 square miles. The population in 1920 was 9,524, of whom 2,179 were foreign-born white; and was 12,377 in 1930 by the Federal census. The falls of Sugar river (223 ft. within the town limits) furnish power for large factories, making shoes, paper, cotton and woollen goods and mining and quarrying machinery. The first settlement here was made in 1762, and the town was organized in 1764. It was named after Lord Clive's country place.

CLARENCE, DUKES OF. The early history of this English title is identical with that of the family of Clare, earls of Gloucester, who are sometimes called earls of Clare, of which word Clarence is a later form. The first duke of Clarence was Lionel of Antwerp (see below), third son of Edward III., who was created duke in 1362, and whose wife Elizabeth was a direct descendant of the Clares, the "Honour of Clare" being among the lands which she brought to her husband. When Lionel died without sons in 1368 the title became extinct; but in 1412 it was revived in favour of Thomas (see below), the second son of Henry IV. The third creation of a duke of Clarence took place in 1461, and was in favour of George (see below), brother of the king Edward IV. When this duke, accused by the king, was attainted and killed in 1478, his titles and estates were forfeited. There appears to have been no other creation of a duke of Clarence until 1789, when William, third son of George III., was made a peer under this title. Having merged in the Crown when William became king of Great Britain and Ireland in 1830, the title of duke of Clarence was again revived in 1890 in favour of Albert Victor (1864-92), the elder son of King Edward VII., then prince of Wales, only to become extinct for the fifth time on his death in 1892. (See EDWARD VII.)

LIONEL OF ANTWERP, duke of Clarence (1338-1368), third son of Edward III., was born at Antwerp on Nov. 29, 1338. Betrothed when a child to Elizabeth (d. 1363), daughter and heiress of William de Burgh, 3rd earl of Ulster (d. 1332), he was married to her in 1352; but before this date he had entered nominally into possession of her great Irish inheritance. Having been named as his father's representative in England in 1345 and again in 1346, Lionel was created earl of Ulster, and joined an expedition into France in 1355, but his chief energies were reserved for the affairs of Ireland. Appointed governor of that country, he landed at Dublin in 1361 and in November of the following year was created duke of Clarence, while his father made an abortive attempt to secure for him the Crown of Scotland. His efforts to secure an effective authority over his Irish lands were only mod-

erately successful; and after holding a parliament at Kilkenny, which passed the celebrated statute of Kilkenny in 1367, he threw up his task in disgust and returned to England. He married Violante, daughter of Galeazzo Visconti, lord of Pavia at Milan in June 1368. Some months were then spent in festivities, during which Lionel was taken ill at Alba, where he died on Oct. 7, 1368. His only child Philippa, a daughter by his first wife, married in 1368 Edmund Mortimer, 3rd earl of March (1351-81), and through this union Clarence became the ancestor of Edward IV. The poet Chaucer was at one time a page in Lionel's household.

THOMAS, duke of Clarence (c. 1388-1421), who was nominally lieutenant of Ireland from 1401-13, and was in command of the English fleet in 1405, acted in opposition to his elder brother, afterwards King Henry V., and the Beauforts during the latter part of the reign of Henry IV.; and was for a short time at the head of the government, leading an unsuccessful expedition into France in 1412. But when Henry V. became king in 1413 no serious dissensions took place between the brothers, and as a member of the royal council Clarence took part in the preparations for the French war. He was with the English king at Harfleur, but not at Agincourt, and shared in the expedition of 1417 into Normandy, during which he led the assault on Caen. On Henry's return to England in 1421, the duke remained in France as his lieutenant, and was killed at Beaugé whilst rashly attacking the French and their Scottish allies on March 22, 1421. He left no legitimate issue, and the title again became extinct.

GEORGE, duke of Clarence (1449-1478), younger son of Richard, duke of York, was born in Dublin on Oct. 21, 1449. Soon after his elder brother became king as Edward IV. in March 1461, he was created duke of Clarence, and his youth was no bar to his appointment as lord-lieutenant of Ireland in 1462. Clarence came under the influence of Richard Neville, earl of Warwick, and in July 1469 was married at Calais to the earl's elder daughter Isabella, although he had been a suitor for the hand of Mary of Burgundy. With his father-in-law he supported the rebels in the north of England. When their treachery was discovered Clarence fled to France. Returning to England with Warwick in Sept. 1470, he witnessed the restoration of Henry VI., when the crown was settled upon himself in case the male line of Henry's family became extinct. But a public reconciliation between the brothers took place when the king was besieging Warwick in Coventry, and Clarence then fought for the Yorkists at Barnet and Tewkesbury. After Warwick's death in April 1471 Clarence appears to have seized the whole of the vast estates of the earl, and in March 1472 was created by right of his wife earl of Warwick and Salisbury. The Warwick estates were eventually divided between Clarence and his younger brother Richard, duke of Gloucester (Richard III.) who married Warwick's younger daughter Anne. Clarence now sought to marry, as his second wife, Mary of Burgundy, now duchess. To this marriage Edward IV. objected. He became convinced that Clarence was aiming at his throne. The duke was thrown into prison, and in Jan. 1478 the king unfolded the charges against his brother to the parliament. He had slandered the king; had received oaths of allegiance to himself and his heirs; had prepared for a new rebellion; and was in short incorrigible. Both houses of parliament passed the bill of attainder, and the sentence of death which followed was carried out on Feb. 17 or 18, 1478. It is uncertain what share Gloucester had in his brother's death; but soon after the event the rumour gained ground that Clarence had been drowned in a butt of malmsey wine. Two of the duke's children survived their father: Margaret, countess of Salisbury (1473-1541), and Edward, earl of Warwick (1475-99), who passed the greater part of his life in prison and was beheaded in Nov. 1499.

On the last named see W. Stubbs, *Constitutional History*, vol. iii. (1895); C. W. C. Oman, *Warwick the Kingmaker* (1891); Sir J. H. Ramsay, *Lancaster and York* (1892).

CLARENDON, EDWARD HYDE, 1ST EARL OF (1609-1674), English statesman and the historian of the Great Rebellion, son of Henry Hyde of Dinton, Wiltshire, was born on Feb. 28, 1609. He entered Magdalen hall, Oxford, in 1622 (having been refused a demyship at Magdalen college), and graduated B.A. in 1626. In 1625 he entered the Middle Temple. At the university

is abilities were more conspicuous than his industry, and at the ar his time was devoted more to general reading and to the society f eminent scholars and writers than to the study of law treatises. among his friends were included Ben Jonson, Selden, Waller, Iales, and especially Lord Falkland.

In 1629 he married Anne, daughter of Sir George Ayliffe, who ied six months afterwards; and secondly, in 1634, Frances, aughter of Sir Thomas Aylesbury, Master of Requests. In 1633 e was called to the bar and quickly obtained a good practice. His arriages had gained for him influential friends, and in Dec. 1634, e was made keeper of the writs and rolls of the common pleas. He was returned to the Short Parliament in 1640 as member for Vootton Bassett. The flagrant violations and perversions of the aw which characterized the 12 preceding years of absolute rule rove Hyde into the ranks of the popular party. He assailed the urisdiction of the earl marshal's court, and in the Long Par- arment, in which he sat for Saltash, renewed his attacks and prac- ically effected its suppression. In 1641 he served on the commit- ees for enquiring into the status of the councils of Wales and of he north, and took an important part in the proceedings against he judges. He supported Strafford's impeachment and did not ote against the attainder, though he made subsequently an un- uccessful attempt through Essex to avert the capital penalty. Hyde's allegiance, however, to the church of England was as taunch as his support of the law, and was soon to separate him rom the popular party. He showed special energy in his opposi- ion to the Root and Branch bill, and, though made chairman of he committee on the bill on July 11 in order to silence his op- osition, he caused by his successful obstruction the failure of the easure. By the beginning of the second session he was regarded s one of the king's ablest supporters in the Commons. He op- osed the demand by the parliament to choose the king's ministers, nd also the Grand Remonstrance, to which he wrote a reply pub- shed by the king.

He now definitely, though not openly, joined the royal cause, nd refused office in Jan. 1642, with Colepeper and Falkland in rder to serve the king's interests more effectually. Charles under- ook to do nothing in the Commons without their advice. Never- theless a few days afterwards, without their knowledge and by the dvices of Lord Digby, he attempted the arrest of the five members, resort to force which reduced Hyde to despair, and which indeed eemed to show that things had gone too far for an appeal to the aw. He persevered, nevertheless, in his legal policy, joined the ing openly in June, and continued to compose the king's answers nd declarations in which he appealed to the "known Laws of the and" against the arbitrary and illegal acts of a seditious majority 1 the parliament, his advice to the king being "to shelter himself /holly under the law . . . presuming that the king and the law to- ether would have been strong enough for any encounter." Hyde's ppeal had great influence, and gained for the king's cause half the ation. It by no means, however, met with universal support mong the royalists, Hobbes jeering at Hyde's love for "mixed ionarchy," and the courtiers expressing their disapproval of the spirit of accommodation" which "wounded the regality." It was estined to failure because Charles was simultaneously carrying n another and an inconsistent policy, listening to very different dvisers, such as the queen and Digby, and resolving on measures ithout Hyde's knowledge or approval.

In spite of Clarendon's efforts war broke out. He was expelled om the House of Commons on Aug. 11, 1642, and was one of ose excepted later from pardon. He was present at Edgehill, ough not as a combatant, and followed the king to Oxford, red- ing at All Souls college from Oct. 1642, till March, 1645. On eb. 22 he was made a privy councillor and knighted, and on arch 3 appointed chancellor of the exchequer. He was an influ- tial member of the "Junto" which met every week to discuss isiness before it was laid before the council. (*See CABINET.*) At e Uxbridge negotiations in Jan. 1645, where he acted as principal anager on the king's side, he tried to win individuals by promises places and honours. He promoted the assembly of the Oxford rliament in Dec. 1643 as a counterpoise to the Long Parliament. yde's policy and measures, however, all failed. They had been

weakly and irregularly supported by the king, and were fiercely opposed by the military party, who were urging Charles to trust to force and arms alone and eschew all compromise and concessions. Charles fell now under the influence of persons devoid of all legal and constitutional scruples.

Hyde's influence was much diminished, and on March 4, 1645, he left the king for Bristol as one of the guardians of the prince of Wales and governors of the west. After Hopton's defeat on Feb. 16, 1646, at Torrington, Hyde accompanied the prince, on March 4, to Scilly, and on April 17, for greater security, to Jersey. He strongly disapproved of the prince's removal to France by the queen's order and of the schemes of assistance from abroad, re- fused to accompany him, and signed a bond to prevent the sale of Jersey to the French supported by Jermyn. He refused to com- pound for his own estate. While in Jersey he resided first at St. Helier and afterwards at Elizabeth Castle with Sir George Carteret. He composed the first portion of his *History* and kept in touch with events by means of an enormous correspondence. In 1648 he published *A Full answer to an infamous and traitorous Pamphlet . . .*, a reply to the resolution of the parliament to present no more addresses to the king and a vindication of Charles.

On the outbreak of the second Civil War Hyde left Jersey (June 26, 1648) to join the queen and prince at Paris. He landed at Dieppe, sailed from that port to Dunkirk, and thence followed the prince to the Thames, where Charles had met the fleet, but was captured and robbed by a privateer, and only joined the prince in September after the latter's return to The Hague. He strongly disapproved of the king's concessions at Newport. When the army broke off the treaty and brought Charles to trial he endeavoured to save his life, and after the execution drew up a letter to the several European sovereigns invoking their assistance to avenge it. Hyde strongly opposed Charles II.'s ignominious surrender to the Covenanters, the alliance with the Scots, and the Scottish expedi- tion, desiring to accomplish whatever was possible there through Montrose and the royalists, and inclined rather to an attempt in Ireland. His advice was not followed and he gladly accepted a mission with Cottington to Spain to obtain money from the Roman Catholic powers, and to arrange an alliance between Owen O'Neill and Ormonde for the recovery of Ireland, arriving at Madrid on Nov. 26, 1649. The defeat, however, of Charles at Dunbar and the confirmation of Cromwell's ascendancy influenced the Spanish Government against them, and they were ordered to leave in Dec. 1650. Hyde arrived at Antwerp in Jan. 1651, and in Dec. rejoined Charles at Paris after the latter's escape from Worcester. He now became one of his chief advisers, accom- panying him in his change of residence to Cologne in Oct. 1654 and to Bruges in 1658, and was appointed lord chancellor on Jan. 13, 1658. His influence was henceforth maintained in spite of the intrigues of both Romanists and Presbyterians, as well as the violent and openly displayed hostility of the queen, and was employed unremittingly in the endeavour to keep Charles faithful to the Church and Constitution, and in the prevention of unwise concessions and promises which might estrange the general body of the royalists. In 1656, during the war between England and Spain, Charles received offers of help from the latter power provided he could gain a port in England, but Hyde discouraged small isolated attempts. He expected much from Cromwell's death. The same year he made an alliance with the Levellers, and was informed of their plots to assassinate the protector, without apparently expressing any disapproval. (*Clarendon State Papers*, iii. 316, 325, 341, 343.) He was well supplied with information from England (*Hist. mss. Comm.: mss. of F. W. Leyborne-Popham*, 227) and guided the action of the royalists with great ability and wisdom during the interval between Cromwell's death and the Restoration, urged patience, and advocated the obstruc- tion of a settlement between the factions contending for power and the fomentation of their jealousies, rather than premature risings.

The Restoration was a complete triumph for Hyde's policy. In his history he lays no stress on his own great part in it, but it was owing to him that the Restoration was a national one, by the consent and invitation of parliament representing the whole people

and not through the medium of one powerful faction enforcing its will upon a minority, and that it was not only a restoration of Charles but a restoration of the monarchy. By Hyde's advice concessions to the inconvenient demands of special factions had been avoided by referring the decision to a "free parliament," and the declaration of Breda reserved for parliament the settlement of the questions of amnesty, religious toleration, and the proprietorship of forfeited lands.

Hyde entered London with the king and immediately obtained the chief place in the Government, retaining the chancellorship of the exchequer till May 13, 1661, when he surrendered it to Lord Ashley. He took his seat as speaker of the House of Lords and in the court of chancery on June 1, 1660. On Nov. 3, 1660, he was made Baron Hyde of Hindon, and on April 20, 1661, Viscount Cornbury and earl of Clarendon, receiving a grant from the king of £20,000 and at different times of various small estates and Irish rents. By the marriage of his daughter Anne to James, duke of York, celebrated in secret in Sept. 1660, he became related to the royal family and the grandfather of two English sovereigns—Queen Mary and Queen Anne.

A rare occasion now offered itself of settling the religious question on a broad principle of comprehension or toleration; for the monarchy had been restored not by the supporters of the Church alone but largely by the influence and aid of the Nonconformists and also of the Roman Catholics, who were all united at that happy moment by a common loyalty to the throne. Clarendon appears to have approved of comprehension but not of toleration. He had already in April 1660 sent to discuss terms with the leading Presbyterians in England, and after the Restoration offered bishoprics to several, including Richard Baxter. He drew up the royal declaration of October, promising limited episcopacy and a revised prayer-book and ritual, which was subsequently thrown out by parliament, and he appears to have anticipated some kind of settlement from the Savoy Conference which sat in April 1661. The failure of the latter proved perhaps that the differences were too great for compromise, and widened the breach. The parliament immediately proceeded to pass, between 1661 and 1665, the series of narrow and tyrannical measures against the dissenters known as the Clarendon Code; the Corporations act, the Act of Uniformity, the Conventicle act, and the Five-Mile act. Though not the originator of the Conventicle act or of the Five-Mile act, Clarendon recorded his approval (*Continuation*, 511, 776) and he ended by taking alarm at plots and rumours and by regarding the great party of Nonconformists, through whose co-operation the monarchy had been restored, as a danger to the state whose "faction was their religion." (*Lister's Life of Clarendon*, ii. 295; *Hist. mss. Comm.: Various Collections*, ii. 379.)

Meanwhile Clarendon's influence and direction had been predominant in nearly all departments of State. He supported the exception of the actual regicides from the Indemnity, but only ten out of the 26 condemned were executed, and Clarendon, with the king's support, prevented the passing of a bill in 1661 for the execution of 13 more. He upheld the Act of Indemnity against all the attempts of the royalists to upset it. The conflicting claims to estates were left to be decided by the law. The confiscations of the usurping Government accordingly were cancelled, while the properly executed transactions between individuals were necessarily upheld. There can be little doubt that the principle followed was the only safe one in the prevailing confusion. The settlement of the Church lands which was directed by Clarendon presented equal difficulties and involved equal hardships. In settling Scotland, Clarendon's aim was to uphold the Cromwellian union. He proposed to establish a council at Whitehall to govern Scottish affairs, and sought to restore episcopacy through the medium of Archbishop Sharp. His influence, however, ended with the ascendancy of Lauderdale in 1663. In Ireland, while anxious for an establishment upon a solid Protestant basis, he urged "temper and moderation and justice" in securing it. He supported Ormonde's wise and enlightened Irish administration, and opposed the prohibition of the import of Irish cattle into England, incurring thereby great unpopularity. He was a member of the council for

foreign plantations, and one of the eight lords proprietors of Carolina in 1663; and in 1664 sent a commission to settle disputes in New England. In the department of foreign affairs he had less influence. In 1664 he demanded, on behalf of Charles, French support, and a loan of £50,000 against disturbance at home, and thus initiated the ignominious system of pensions and dependence upon France. But he was the promoter neither of the sale of Dunkirk on Oct. 27, 1662, the author of which seems to have been the earl of Sandwich (*Hist. mss. Comm.: mss. of F. W. Leyborne-Popham*, 250), nor of the Dutch war. He attached considerable value to the possession of Dunkirk, but when its sale was decided he conducted the negotiations and effected the bargain. He had concluded a treaty for the settlement of disputes with Holland on Sept. 4, 1662. But when hostilities were declared on Feb. 22, 1665, Clarendon gave his support to the war, asserted the extreme claims of the English Crown over the British seas, and contemplated fresh cessions from the Dutch and an alliance with Sweden and Spain. According to his own account he initiated the policy of the Triple Alliance (*Continuation*, 1066), but it seems clear that his inclination towards France continued in spite of French intervention in favour of Holland; and he took part in the negotiations for ending the war by an undertaking with Louis XIV. implying neutrality, while the latter seized Flanders. The crisis in this feeble foreign policy and in the general official mismanagement was reached in June 1667, when the Dutch burned several ships at Chatham.

The whole responsibility for the national calamity and disgrace was unjustly thrown on the shoulders of Clarendon. He was unpopular among all classes: among the royalists on account of the Act of Indemnity, among the Presbyterians because of the Act of Uniformity. Every kind of maladministration was currently ascribed to him, of designs to govern by a standing army, and of corruption. He was credited with having married Charles purposely to a barren queen in order to raise his own grandchildren to the throne, with having sold Dunkirk to France, and his magnificent house in St. James's was nicknamed "Dunkirk House," while on the day of the Dutch attack on Chatham the mob set up a gibbet at his gate and broke his windows. He was disliked by the royal mistresses, whose favour he did not condescend to seek, and whose presence often aroused his reproaches. Surrounded by such general and violent animosity, Clarendon's only hope could be in the support of the king. But Charles, long weary of the old chancellor's rebukes, was especially incensed at this time owing to his failure in securing Frances Stuart (la Belle Stuart) for his seraglio—a disappointment which he attributed to Clarendon—and was now alarmed by the hostility which his administration had excited. He did not scruple to sacrifice at once the old adherent of his house and fortunes. By the direction of Charles, James advised Clarendon to resign before the meeting of parliament, but in an interview with the king on Aug. 26, Clarendon refused to deliver up the seal unless dismissed. On Aug. 30 he was deprived of the great seal, for which the king received the thanks of the parliament on Oct. 16. On Nov. 12 his impeachment was brought up to the Lords, but the latter refused to order his committal, on the ground that the Commons had only accused him of treason in general without specifying any particular charge. Clarendon wrote humbly to the king asking for pardon and that the prosecution might be prevented, but Charles had openly taken part against him, and, though desiring his escape, would not order or assist his departure for fear of the Commons. Through the bishop of Hereford, however, on Nov. 29 he pressed Clarendon to fly, promising that he should not during his absence suffer in his honour or fortune. Clarendon embarked the same night for Calais, where he arrived on Dec. 2. The Lords immediately passed an act for his banishment and ordered the petition forwarded by him to parliament to be burnt.

The rest of Clarendon's life was passed in exile in various parts of France. His sudden banishment entailed great personal hardships. On arriving at Calais he fell dangerously ill; and Louis XIV., anxious to propitiate England, sent him peremptory and repeated orders to quit France. At Evreux, on April 23, 1668, he was the victim of a murderous assault by English sailors, who

attributed to him the non-payment of their wages. For some time he was not allowed to see any of his children; even correspondence with him was rendered treasonable by the Act of Banishment.

Clarendon bore his troubles with great dignity and fortitude. He found consolation in religious duties, and devoted a portion of every day to the composition of his *Contemplations on the Psalms* and of his moral essays. He now finished his *History* and his *Autobiography*. Soon after reaching Calais he had written, on Dec. 17, 1667, to the university of Oxford, desiring as his last request that the university should believe in his innocence and remember him, though there could be no further mention of him in their public devotions, in their private prayers. (*Clarendon St. Pap.* iii., suppl. xxxvii.) He entertained to the last hopes of obtaining leave to return to England, but his petitions were not even answered or noticed. He died at Rouen on Dec. 9, 1674. He was buried in Westminster Abbey at the foot of the steps leading to the Henry VII. chapel. He left two sons, Henry, 2nd earl of Clarendon, and Lawrence, earl of Rochester, and a daughter Anne, duchess of York; a third son, Edward, having predeceased him.

As a statesman Clarendon had obvious limitations and failings. He brought to the consideration of political questions an essentially legal but also a narrow mind, conceiving the law, "that great and admirable mystery," and the constitution as fixed, unchangeable, and sufficient for all time, in contrast to Pym, who regarded them as living organisms capable of continual development and evolution; and he was incapable of comprehending and governing the new conditions and forces created by the civil wars. His character, however, and therefore, to some extent, his career bear the indelible marks of greatness. He maintained his self-respect and dignity at a licentious court, and his integrity in an age of almost universal corruption. His industry and devotion to public business were rendered all the more conspicuous by the negligence, inferiority in business, and frivolity of his successors. As lord chancellor Clarendon made no great impression in the court of chancery. His early legal training had long been interrupted, and his political preoccupations probably rendered necessary the delegation of many of his judicial duties to others. As chancellor of Oxford university, Clarendon promoted the restoration of order and various educational reforms. In 1753 his manuscripts were left to the university by his grandson Lord Cornbury, and in 1868 the money gained by publication was spent in erecting the Clarendon laboratory, the profits of the *History* having provided in 1713 a building for the university press adjoining the Sheldonian theatre, known since the removal of the press to its present quarters as the Clarendon building.

As a writer and historian Clarendon occupies a high place in English literature. His great work, the *History of the Rebellion*, is composed in the grand style. A characteristic feature is the wonderful series of well-known portraits, drawn with great skill and liveliness and especially praised by Evelyn and by Macaulay. The book is overloaded, however, with State papers, misplaced and tedious in the narrative. The published *History* is mainly a compilation of two separate original manuscripts, the first being the history proper, written between 1646 and 1648, with the advantage of a fresh memory and the help of various documents and authorities, and ending in March, 1644, and the second being the *Life*, extending from 1609-60, but composed long afterwards in exile and without the aid of papers between 1668 and 1670. The value of any statement, therefore, in the published *History* depends chiefly on whether it is taken from the *History* proper or the *Life*. In 1671 these two manuscripts were united by Clarendon with certain alterations and modifications making Books i.-vii. of the published *History*, while Books viii.-xv., were written subsequently, and, being composed for the most part without materials, are generally inaccurate, with the notable exception of Book ix., made up from two narratives written at Jersey in 1646, and containing very little from the *Life*. The inaccuracies are due not to wilful misrepresentation, but to failure of memory and to the disadvantages under which the author laboured in exile. In general, Clarendon, like many of his contemporaries, failed signally to comprehend the real issues and principles at stake in the great

struggle, laying far too much stress on personalities and never understanding the real aims and motives of the Presbyterian party.

BIBLIOGRAPHY.—1. *Editions of the History*: The work was first published in 1702-04 from a copy of a transcript made by Clarendon's secretary, with a few unimportant alterations, and was the object of a violent attack by John Oldmixon for supposed changes and omissions in *Clarendon and Whitelocke compared* (1727) and again in a preface to his *History of England* (1730), repelled and refuted by John Burton in the *Genuineness of Lord Clarendon's History Vindicated* (1744). The history was first published from the original in 1826; the best edition being that of 1888 edited by W. D. Macray and issued by the Clarendon Press. *The Lord Clarendon's History . . . Completed*, a supplement containing portraits and illustrative papers, was published in 1717, and *An Appendix to the History*, containing a life, speeches, and various pieces, in 1724. The *Sutherland Clarendon* in the Bodleian library at Oxford contains several thousand portraits and illustrations of the *History*. *The Life of Edward, earl of Clarendon . . . (and the) Continuation of the History . . .* the first consisting of that portion of the *Life* not included in the *History*, and the second of the account of Clarendon's administration and exile in France, begun in 1672, was published in 1759, the *History of the Reign of King Charles II. from the Restoration . . .* published about 1755, being a surreptitious edition of this work, of which the latest and best edition is that of the Clarendon Press of 1857.

2. *Other works*: Among Clarendon's other works may be mentioned *A Brief View . . . of the dangerous . . . errors in . . . Mr. Hobbes's book entitled "Leviathan"* (1676); *The History of the Rebellion and Civil War in Ireland* (1719); *Essays moral and entertaining on the various faculties and passions of the human mind* (pr. 1815, and in *British Prose Writers*, vol. i., 1819); a large number of declarations and manifestos in various collections of tracts and several anonymous tracts, a list of which will be found in the authorities quoted below.

3. *Correspondence*: Clarendon's correspondence, amounting to over 100 volumes, is in the Bodleian library at Oxford, and other letters are to be found in *Additional mss.* in the British Museum. Selections have been published under the title of *State Papers Collected by Edward, earl of Clarendon* (Clarendon State Papers) between 1767 and 1786, and the collection has been calendared up to 1657 in 1869, 1872, 1876. Other letters of Clarendon are to be found in *Lister's Life of Clarendon*, iii.; *Nicholas Papers* (Camden Soc., 1886); *Diary of J. Evelyn*, appendix; Sir R. Fanshawe's *Original Letters* (1724); Warburton's *Life of Prince Rupert* (1849); Barwick's *Life of Barwick* (1724); *Hist. mss. Comm.* 10th Rep. pt. vi. pp. 193-216, and in the *Harleian Miscellany*.

4. *Life*: See Clarendon's autobiographical works and Letters enumerated above, and the ms. collection in the Bodleian library. The *Lives* of Clarendon by T. H. Lister (1838) and by C. H. Firth in the *Dict. of Nat. Biography* (with authorities there collected) completely supersede all earlier accounts.

See also S. R. Gardiner, *History of England, of the Civil War and of the Commonwealth* (1886-1901); a series of articles by C. H. Firth in the *Eng. Hist. Review* (1904) and *Edward Hyde, earl of Clarendon, as Statesman, Historian, and Chancellor of the University* (1909), by the same author; Sir Henry Craik, *The Life of Edward, earl of Clarendon* (1911).

CLARENDON, GEORGE WILLIAM FREDERICK VILLIERS, 4TH EARL OF (in the Villiers line) (1800-1870), British diplomatist and statesman, the eldest son of George Villiers, who was the youngest son of the 1st earl of the new creation, and Theresa, only daughter of the first Lord Boringdon, was born in London on Jan. 12, 1800. He was educated at Christ's hospital and St. John's college, Cambridge, and became an attaché at the British embassy in St. Petersburg in 1820, where he remained until he was appointed a commissioner of customs in 1823, an office he held until his appointment as British minister at Madrid in 1833. At Madrid he distinguished himself by the skill with which he conducted the difficult negotiations arising out of the Spanish Succession question (see SPAIN: *History*) in which he supported the Liberal Government of Isabella II. In 1838 his services were rewarded by the G. C. B. and in the same year he succeeded his uncle as 4th earl; he married Katherine, daughter of the first earl of Verulam, in 1839. In Lord Melbourne's Administration (1840-1841) Lord Clarendon held office as lord privy seal and chancellor of the duchy of Lancaster; but he disagreed with Palmerston's Egyptian and French policy. For five years Clarendon formed one of the opposition to Peel's Government, but when Russell became prime minister in 1846, Clarendon entered the Cabinet as president of the Board of Trade. He twice refused the viceroyalty of India and once the governor-generalship of Canada, and it was with very great reluctance that at Russell's urgent request he undertook in 1847 the lord-lieutenancy of

Ireland. He remained in Ireland until 1852 and guided that country with great skill and sympathy through one of the worst crises in her history (*see IRELAND: History*). On the formation of Aberdeen's Coalition Ministry in 1853 Clarendon attained his ambition by becoming secretary of State for Foreign Affairs. Almost from the outset of his tenure of office he found himself confronted with a renewed outbreak of the old Turko-Russian trouble in the Near East that led to the Crimean War (*see ENGLAND: History*) and the Congress of Paris. Clarendon's diplomacy was directed to securing peace on an equable basis and to forcing Austria either to maintain her neutrality or participate actively in the war on the Allied side. His influence over the emperor Napoleon was of incalculable value to the Allies in keeping that unreliable monarch faithful to the alliance, and he won for himself an international prestige by his skilful handling of the congress. Through his support Cavour was enabled to bring the Italian question before Europe, and he was personally responsible for the greatest work accomplished by the congress, the Declaration laying down the rules of maritime warfare. Personal rivalry between Clarendon and Lord John Russell led to the exclusion of the former from the reconstituted Ministry of 1859, and it was not until 1864 that he again held office, this time as chancellor of the duchy of Lancaster. On Palmerston's death in 1865 Clarendon once more returned to the Foreign Office, where he remained until his death on June 27, 1870.

The three outstanding achievements of Clarendon's life were his handling of the Spanish Succession question, his conduct of negotiations during the Crimean War and his services to international law in obtaining the consent of the Congress of Paris to the Maritime Declaration. His final tenure of the Foreign Office was distinguished by his able conduct of affairs during the critical days of the Schleswig-Holstein question, the Austro-Prussian war of 1866, the Alabama question and the troubled days preceding the outbreak of the war between France and Prussia which he feared but did not live to see. Singularly handsome, a man of great courtesy and distinction of manner, cultivated and witty, Clarendon can hardly be reckoned among the greatest of English statesmen. Yet that his was no mean ability is revealed by Bismarck's striking statement that had Clarendon lived, "he would have prevented the war" (*i.e.*, the Franco-Prussian War) and by so doing destroyed Bismarck's life work.

See Sir Herbert Maxwell, *The Life and Letters of the Fourth Earl of Clarendon* (2 vols., London, 1913); Algernon Cecil, *British Foreign Secretaries* (1927).

CLARENDON, HENRY HYDE, 2ND EARL OF (1638–1709), English statesman, eldest son of the historian, was born on June 2, 1638, and succeeded to the title on his father's death in 1674. James II. made him lord-lieutenant of Ireland (Sept. 1685) with a commission to carry out his design of replacing Protestants in high positions in Ireland by Roman Catholics. He was recalled in Jan. 1687. At the time of the revolution he played a vacillating part, but opposed the settlement of the crown on William and Mary, and remained a non-juror all his life. On June 24, 1690, he was arrested, by order of his niece Queen Mary, on a charge of plotting against William, and though liberated for a time, was again imprisoned in Jan. 1691 on the evidence of Richard Graham, Lord Preston. He was released in July of that year, and from that time until his death, on Oct. 31, 1709, lived in retirement.

His public career had been neither distinguished nor useful, but it seems natural to ascribe its failure to small abilities and to the conflict between personal ties and political convictions which drew him in opposite directions, rather than, following Macaulay, to motives of self-interest. He was a man of some literary taste, a fellow of the Royal Society (1684), the author of *The History and Antiquities of the Cathedral Church . . . continued by S. Gale* (1715), and he collaborated with his brother Rochester in the publication of his father's *History* (1702–04).

He was succeeded by his only son, Edward (1661–1724), as 3rd earl of Clarendon; and, the latter having no surviving son, the title passed to Henry, 2nd earl of Rochester (1672–1753), at whose death without male heirs it became extinct in the Hyde

line. (For the other Clarendon line, *see* above.)

CLARENDON, CONSTITUTIONS OF, a body of English laws issued at Clarendon in 1164, by which Henry II. endeavoured to settle the relations between church and state. They purported to declare the usages on the subject in the reign of Henry I. They were never accepted in full by the clergy and after Becket's murder Henry II. was unable to maintain them all. Of the 16 provisions the one which provoked the greatest opposition was that which declared in effect that criminous clerks were to be summoned to the king's court, and from there, after formal accusation and defence, sent to the proper ecclesiastical court for trial. If found guilty they were to be degraded and sent back to the king's court for punishment. Another provision, which in spite of all opposition obtained a permanent place in English law, declared that all suits, even between clerk and clerk, concerning advowsons and presentations should be tried in the king's court. By other provisions appeals to Rome without the licence of the king were forbidden. None of the clergy was to leave the realm, nor were the king's tenants-in-chief and ministers to be excommunicated or their lands interdicted without the royal permission. Pleas of debt, whether involving a question of good faith or not, were to be in the jurisdiction of the king's courts. Two interesting provisions, to which the clergy offered no opposition, were: (1) if a dispute arose between a clerk and a layman concerning a tenement, which the clerk claimed as free-*alms* (*frankalmoign*) and the layman as a lay-fee, it should be determined by the recognition of 12 lawful men before the king's justice whether it belonged to free-*alms* or lay-fee, and if it were found to belong to free-*alms* then the plea was to be held in the ecclesiastical court, but if to lay-fee, in the court of the king or of one of his magnates; (2) a declaration of the procedure for election to bishoprics and royal abbeyes, generally considered to state the terms of the settlement made between Henry I. and Anselm in 1107.

W. Maitland, *Roman Canon Law in the Church of England* (1898); the text of the Constitutions is printed by Stubbs in *Select Charters* (1913). (G. J. T.)

CLARES, POOR, otherwise **CLARISSES**, Franciscan nuns, so called from their foundress, St. Clara (*q.v.*). She was professed by St. Francis in the Portiuncula in 1212, and two years later she and her first companions were established in the convent of St. Damian at Assisi. The nuns formed the "Second Order of St. Francis," the friars being the "First Order," and the Tertiaries (*q.v.*) the "Third." Before Clara's death in 1253, the Second Order had spread all over Italy and into Spain, France and Germany; in England they were introduced *c.* 1293 and established in London, outside Aldgate, where their name of Minoreesses survives in the Minories; there were only two other English houses before the Dissolution. St. Francis gave the nuns no rule, but only a "Form of Life" and a "Last Will," each only five lines long, and coming to no more than an inculcation of his idea of evangelical poverty. Something more than this became necessary as soon as the institute began to spread; and during Francis's absence in the East, 1219, his supporter Cardinal Hugolino composed a rule which made the Franciscan nuns practically a species of unduly strict Benedictines, St. Francis's special characteristics being eliminated. St. Clara made it her life work to have this rule altered, and to get the Franciscan character of the Second Order restored; in 1247 a "Second Rule" was approved which went a long way towards satisfying her desires, and finally in 1253 a "Third," which practically gave what she wanted. This rule has come to be known as the "Rule of the Clares"; it is one of great poverty, seclusion and austerity of life. Most of the convents adopted it, but several clung to that of 1247. To bring about conformity, St. Bonaventura, while general (1264), obtained papal permission to modify the rule of 1253, somewhat mitigating its austerities and allowing the convents to have fixed incomes. This rule was adopted in many convents, but many more adhered to the strict rule of 1253. Indeed a counter-tendency towards a greater strictness set in, and a number of reforms were initiated, introducing an appalling austerity of life.

See Heimbucher, *Orden und Kongregationen* (1896), i. §§ 47, 48, who gives references to all the literature; and *Catholic Encyclopaedia*, art. "Claret."

CLARET, the name by which the red wines of Bordeaux are known among the English-speaking people. In the 12th and 13th centuries, claret meant a red wine lighter in colour than the dark red (almost black) wines of southern Europe, and it was even sometimes made up of a blend of red and white wines. Thus, on Nov. 18, 1251, Henry III. ordered the keeper of the royal cellars at York to deliver to one Robert de Montpellier two casks of white wine and one cask of red wine "to make *claret* thereof." During the three centuries of English rule in Aquitaine, the merchants of Bordeaux enjoying in England all the privileges of subjects of the crown, and the king's eldest son having none but the taxes levied at Bordeaux to replenish his exchequer, the consumption of the wines of Bordeaux was greatly encouraged in England and immense quantities of red and white wines, but more particularly of claret wines, reached London and the outports from Bordeaux every year. All the wines made in Aquitaine, and much of the Languedoc wine, came to Bordeaux to be shipped, and they were sold in England under the name of red, white or claret wines. Claret wines were the most popular; they were those made from the vineyards of Bordeaux, vineyards which have always produced and still produce red wines of greater brilliance and lighter in colour than the vineyards of what was known in the middle ages as the "high country," towards the Pyrenees. Thus it came to pass gradually that the name claret acquired a much more restricted meaning, a geographical instead of a generic meaning. It has been used in England since the 17th century to refer exclusively to the red wines of Bordeaux. During the Hundred Years War and since, whenever hostilities between England and France broke out, the sale of English woollens was prohibited in France and claret was penalized in England either by total prohibition or by the imposition of prohibitive duties. Early in the 19th century claret, which cost a penny a gallon in Chaucer's day, cost a pound a bottle in England: the consumption was very small and restricted entirely to the finest clarets.

On Feb. 29, 1860, the duty on French wines, which had been 5s. 9d. per gallon since 1832, was replaced by a duty of 3s. per gallon on every description of wine. On Jan. 1, 1861, this uniform duty was superseded by a scale of duties based on the alcoholic contents of every wine, beginning with a shilling per gallon rate on wines not exceeding 18° of proof spirit and rising to 2s. 11d. per gallon on wines of greater alcoholic strength. The following year, on April 3, 1862, the duty on wines was once more altered and made far simpler, all wines not exceeding 26° of proof spirit paying one shilling per gallon and others, up to 42°, half-a-crown per gallon. As this reduction of duty upon the low-strength or natural wines coincided with a series of very plentiful vintages at Bordeaux, claret reached the consumer, in England, in large quantities, in great variety and at remarkably low prices, so that claret became once more the most popular beverage wine in England.

The excellence of claret, and the reason why it may rightly claim precedence over all other wines is that it is the most harmonious and natural of all wines. In the making of claret, the art of man intervenes only to remove every possible cause of imperfection, but not to assist nor to hamper nature. Nothing is added either to the "must" or the wine to improve its colour, body, flavour or alcoholic strength. One of the great charms of claret is that it adapts itself to all tastes, constitutions and purses. The varieties of claret, the difference in excellence and in price, in type and style, are much greater than is the case with other wines.

CLARETIE, JULES ARSÈNE ARNAUD (1840-1913), French writer, director of the Théâtre Français, was born at Limoges Dec. 3, 1840. He was dramatic critic to the *Figaro* and to the *Opinion nationale*, a newspaper correspondent during the Franco-German War, and during the Commune a staff-officer in the National Guard. In 1885 he became director of the Théâtre Français, and from that time devoted himself chiefly to its administration. He was elected a member of the Academy in 1888. He died in Paris on Dec. 23, 1913.

The long list of his works includes *Histoire de la révolution de 1870-71* (new ed., 5 vols., 1875-76); *Cinq ans après: l'Alsace et la Lorraine depuis l'annexion* (1876); some annual volumes of reprint of his articles in the weekly press, entitled *La Vie à Paris*; *La Vie moderne au théâtre* (1868-69); *Molière, sa vie et son œuvre* (1871); *Histoire de la littérature française, 900-1900* (2nd ed. 1905); *Candidat* (1887), a novel of contemporary life; *Brichanteau, comédien français* (1896); several plays, some of which are based on novels of his own and the opera, *La Navarraise* based on his novel *La Cigarette*, an written with Henri Cain to the music of Massenet. *La Navarraise* was first produced at Covent Garden (June 1894) with Mme. Calvé in the part of Anita. His *Oeuvres complètes* were published in 1897-1904. See G. Grappe, *Jules Claretie* (1906).

CLARI, GIOVANNI CARLO MARIA (c. 1669-1745), Italian musical composer, born at Pisa, was the most celebrated pupil of Colonna, chapel-master of S. Petronio, at Bologna. He became *maestro di cappella* at Pistoia about 1712, at Bologna in 1720, and at Pisa in 1736. The works by which Clari distinguishes himself preeminently are his vocal duets and trios, with a *basso continuo*, published between 1740 and 1747. These compositions which combine graceful melody with contrapuntal learning, were much admired by Cherubini and also by Handel, who appropriated portions of them. Clari composed one opera, *Il Savio delirante* produced at Bologna in 1695, and a large quantity of church music, several specimens of which have been printed in Novello's *Fitzwilliam Music*.

"**CLARIN**": see ALAS, LEOPOLDO.

CLARINA, a modern instrument of the wood-wind class (although actually made of metal), a hybrid possessing characteristics of both oboe and clarinet. The clarina was invented by W. Heckel of Biebrich-am-Rhein, and has been used at Bayreuth, in *Tristan und Isolde*, as a substitute for the *Holztrumpet* made according to Wagner's instructions.

CLARINDA, a city of south-western Iowa, U.S.A., on the Nodaway river, Federal highway 71, and the Burlington (railway) route; the county seat of Page county. The population in 1930 (Federal census) was 4,962. It has a variety of manufacturing industries and a large wholesale trade in poultry, butter and eggs and seed. A State hospital for the insane, with a capacity for 1,200 patients, is here. Clarinda was settled about 1853 and incorporated in 1866.

CLARINET, a wood-wind instrument having a cylindrical bore and played by means of a single-reed mouthpiece. The name is sometimes used in a generic sense to denote the whole family which consists of the clarinet or discant, corresponding to the violin, oboe, etc.; the alto clarinet in E; the bass horn in F (q.v.); the bass clarinet (q.v.), and the pedal clarinet (q.v.).

The mouthpiece of the clarinet, including the beating or single reed common to the whole clarinet family, has the appearance of a beak with the point bevelled off and thinned at the edge to correspond with the end of the reed shaped like a spatula. The under part of the mouthpiece is flattened in order to form a table for the support of the reed, which is adjusted thereon with great nicety, allowing just the amount of play requisite to set in vibration the column of air within the tube.

A cylindrical tube played by means of a reed has the acoustic properties of a stopped pipe, i.e., the fundamental tone produced by the tube is an octave lower than the corresponding tone of an open pipe of the same length, and overblows a twelfth; whereas tubes having a conical bore like the oboe, and played by means of a reed, speak as open pipes and overblow an octave. This forms the fundamental difference between the instruments of the oboe and clarinet families.

Wind instruments depending upon lateral holes for the production of their scale must either have as many holes pierced in

the bore as they require notes, or make use of the property possessed by the air-column of dividing into harmonics or partials of the fundamental tones. Twenty to twenty-two holes is the number generally accepted as the practical limit for the clarinet. The compass of the instrument is therefore extended through the medium of the harmonic overtones.

In order to facilitate, however, the production of the harmonic notes, a small hole, closed by means of a key and called the "speaker," is bored near the mouthpiece. By means of this small hole the air-column is placed in communication with the external

BY COURTESY OF MESSRS. CARL FISCHER

THE CLARINET, A MUSICAL INSTRUMENT WITH A SINGLE BEATING REED, DERIVED FROM THE CHALUMEAU OF THE MIDDLE AGES

atmosphere, a ventral segment is formed, and the air-column divides into three equal parts, producing a triple number of vibrations resulting in the third note of the harmonic series, at an interval of a twelfth above the fundamental.

The fundamental scale of the modern clarinet in C extends from E in the bass clef to B flat in the treble. The next octave and a half is obtained by opening the speaker key, whereby each of the fundamental notes is reproduced a twelfth higher, extending the range to F in alt, which ends the natural compass of the instrument, although a skilful performer may obtain another octave by cross-fingering.

History.—The single beating-reed associated with the instruments of the clarinet family was probably introduced into classic Greece from Egypt or Asia Minor. A few ancient Greek instruments are extant, five of which are in the British Museum. They are as nearly cylindrical as would be the natural growing reed itself. The probability is that both single and double reeds were at times used with the Greek aulos and the Roman tibia.

In the West, the instrument was, during the Carolingian period, identified with the tibia of the Romans until such time as the new western civilization ceased to be content to go back to classical Rome for its models, and began to express itself, at first naively and awkwardly, as the 11th century dawned. The name then changed to the derivatives of the Greek *kalamos*, assuming an almost bewildering variety of forms, of which the commonest are chalemie, chalumeau, schalmey, scalmeye, shawm, calemel, kalemele.

At the beginning of the 18th century various important improvements in the mechanism of the instrument, in particular the invention of the very useful device of the speaker-key—to facilitate the production of the harmonics of the fundamental—were effected by J. Christian Denner (1655–1707), and after various subsequent developments the instrument was further improved during the 19th century by the Belgian makers Bachmann, the elder Sax, Albert and C. Mahillon and others. In England the clarinet has also passed through several progressive stages since its introduction about 1770, first at the hands of Cornelius Ward, and later, as a consequence of still more important improvements due to Richard Carte and others.

As regards music for the clarinet, Mattheson mentions clarinet music in 1713, although Handel, whose rival he was, does not appear to have known the instrument. Joh. Christ. Bach scored for the clarinet in 1763 in his opera *Orione*, performed in London, and Rameau had already employed the instrument in 1751 in a theatre for his pastoral entitled *Acante et Céphise*. Later, Mozart wrote for it in his Paris symphony, and since then it has of course long since taken its place as one of the most indispensable members of the orchestral family.

CLARK, ABRAHAM (1726–1794), American patriot and signer of the Declaration of Independence, was born in Elizabethtown, N.J., on Feb. 15, 1726. After receiving his education in mathematics and civil law, he engaged in conveyancing and surveying. Though he did not enter the professional practice of law,

he gave legal advice gratuitously to his neighbours, earning the title, "the poor man's counsellor." He served as clerk of the New Jersey colonial assembly, and later was appointed high sheriff of Essex county. As an active Whig, he served on the committees of vigilance and public safety in his native State, and in June 1776 was appointed a representative to the general Congress, where he voted for separation from England and signed the Declaration of Independence. Eight times in the following 12 years he was elected a member of that body, and he was chosen a delegate to the Constitutional Convention in Philadelphia in 1787, but illness prevented his attendance. In Congress, on Wednesday, July 2, 1788, he made the motion by which the Federal Constitution became effective. The State legislature appointed him, in the winter of 1789–90, a commissioner to settle debts of New Jersey contracted during the Revolution, which duties he discharged until elected a member of the second Congress. This office he held until June 1794. He died at Elizabethtown, N.J., on Sept. 15, 1794.

See A. C. Hart, ed., *Abraham Clark* (San Francisco, 1923).

CLARK, SIR ANDREW (1826–1893), British physician, was born at Aberdeen on Oct. 28, 1826, and died in London on Nov. 6, 1893. After studying at Aberdeen and Edinburgh he showed symptoms of tuberculosis and joined the navy medical department for the sake of the sea voyages. Actually he served at Haslar Hospital, and in 1853 retired from the service, became curator of the museum of the London Hospital, and next year assistant physician there. In 1888 he became president of the College of Physicians, an office which he continued to hold till his death on Nov. 6, 1893. Though busy, he wrote many books, all in precise and polished style. Doubtless owing largely to personal reasons, lung diseases and especially fibroid phthisis formed his favourite theme but he also discussed other subjects, such as renal inadequacy, anaemia, constipation, etc.

See MacColl and Allchin, *Life of Sir Andrew Clark* (1896).

CLARK, CHAMP (1850–1921), American politician, was born in Anderson Co., Ky., on March 7, 1850. He first entered Kentucky university but finished his course at Bethany college in 1873. The following year he was elected president of Marshall college, West Virginia, and one year later was admitted to the bar. After 1880 his law office was in Bowling Green, Missouri. He was city attorney for Louisiana, Mo., and for Bowling Green from 1878 to 1881; and was prosecuting attorney for Pike Co., 1885–89, and then for three years was a member of the Missouri house of representatives. He was a member of Congress from 1893 to 1895, and from 1897 to 1919, being speaker from 1911 to 1919. At the Democratic Convention for the nomination of a presidential candidate held at Baltimore in 1912, he led on 27 ballots and on 8 had a clear majority, but not the necessary two-thirds. He was finally defeated by Woodrow Wilson of New Jersey. He died in Washington, D.C., on March 2, 1921.

CLARK, FRANCIS EDWARD (1851–1927), American clergyman, was born of New England ancestry at Aylmer, Province of Quebec, Canada, Sept. 12, 1851. He graduated at Dartmouth college in 1873 and at Andover theological seminary in 1876, and was pastor successively of the Williston Congregational church in Portland, Me., and of the Phillips Congregational church in South Boston, Mass. In Feb. 1881 he founded at Portland the Young People's Society of Christian Endeavour, which beginning as a small society in a single New England church, developed into a great interdenominational organization, which in 1908 reported 80,000 societies and more than 4,000,000 members throughout the world. For many years he devoted himself to this work as president and finally president emeritus of the United Societies of Christian Endeavour and president of the World's Christian Endeavour Union, and as editor, and then honorary editor of the *Christian Endeavor World* until his death at Newton, Mass., on May 26, 1927.

Among his publications are *Looking Out on Life* (1883); *World Wide Endeavor* (1895); *Christian Endeavor Manual* (1903); and *Christian Endeavor in All Lands* (1906). *The Continent of Opportunity* (1909); *Old Home of New Americans* (1912); *The Holy Land of Asia Minor* (1914); *The Charm of Scandinavia* (with Sydney A. Clark) (1914); *Christ and the Young People* (1916); *In the Footsteps of St. Paul* (1917); *The Gospel of Out-of-Doors* (1920); *Memories of Many Men in Many Lands* (1923).

CLARK, GEORGE ROGERS (1752-1818), American frontier military leader, was born in Albemarle county, Virginia, on Nov. 19, 1752. When 19 years of age he left his home to become a surveyor of frontier lands along the Ohio river. This occupation was soon interrupted by an Indian outbreak known as Lord Dunmore's War (1774); and Clark, with the rank of captain, accompanied Dunmore in the punitive expedition. Peace brought renewed immigration, especially into Kentucky, and thither Clark followed as a surveyor for the Ohio company. His position enabled him from time to time to absorb choice portions of land for himself, and these interests soon led him to identify himself with the Kentuckians and devote much thought to their peculiar problems. When the American Revolution broke out Clark clearly perceived the vulnerability of the frontier, and the necessity of securing for Kentucky a government with military authority and an organized militia if there was to be concerted defence against the British, or their allies, the Indians. Elected by a mass meeting of the pioneers to present their problems before the Virginia Government, Clark attended the council and assembly at Williamsburg and diplomatically persuaded them to create a separate county of Kentucky and thereby become responsible for its defence. Clark returned with a supply of powder and assumed chief command of the frontier militia at a critical moment, for the Indians were already making raids against the settlers. Convinced that they were instigated and supported in their raids by British officers stationed in the forts north of the Ohio river, Clark worked out a plan of offensive operations that involved nothing less than a conquest of these forts. His plans were approved by Governor Patrick Henry and the council of Virginia and Clark was authorized to enlist troops. May 1778 found him at the falls of the Ohio with about 175 men. The expedition proceeded to Ft. Kaskaskia, on the Mississippi river, in what is now Illinois. This place and Cahokia, also on the Mississippi, near St. Louis, were defended by small British garrisons, which depended on the support of the French inhabitants. The French being willing to accept the authority of Virginia, both forts were easily taken. Clark gained the friendship of Father Gibault, the priest at Kaskaskia, and through his influence the French at Vincennes on the Wabash were induced to change their allegiance. Lieut.-governor Hamilton, the British commander at Detroit, recovered Vincennes, however, and went into winter quarters there. After an arduous march across flooded bottom land in freezing weather, Clark in Feb. 1779, surprised Hamilton and forced him to give up Vincennes, and surrender himself and his garrison as prisoners of war. The way was now open to Detroit, Clark's ultimate object, but it was deemed prudent to wait for reinforcements promised from Virginia in June. The delay was fatal; other occurrences delayed the reinforcements and scattered Clark's troops. Clark withdrew to Ft. Nelson which he had built at the falls of the Ohio, and made that his base for the rest of the war. In 1780 he aided in the defeat of a British expedition against the Spanish settlement of St. Louis; the same year he made a swift campaign against the Shawnee Indians and destroyed their towns, Chillicothe and Piqua. Clark, now appointed brigadier-general of the western forces, again planned to move against Detroit and was promised supplies and reinforcements for the expedition from Virginia. Months went by and they did not come, for Virginia was bankrupt. Again in 1782 Clark took the offensive against the Shawnees, and while not entirely successful this last expedition saved the settlements from renewed Indian attacks and defeated British plans for an Indian alliance. When peace came in 1783 (Treaty of Paris) Clark's conquests doubtless influenced the award of the country northwest of the Ohio to the United States. His offensive movements had also been of first importance in defending the vulnerable frontier from Indian raids and British expeditions. Clark and his men during all these years received no pay for their services and hardships. Furthermore Clark found himself responsible for all debts incurred for supplies, since Virginia, despite her promises, never reimbursed him. The rest of his life was shadowed by the constant demands of creditors. Clark was appointed an Indian commissioner after the war, and in 1786 he played a leading part in a treaty with the Shawnees.

The same year he led an expedition against the "Wabash confederacy," his last military command. James Wilkenson, a traitor in the pay of Spain (unknown at that time), coveted Clark's office of Indian commissioner and his military command, and deliberately set out to misrepresent him. Forged papers and testimonials were forwarded to Governor Randolph of Kentucky charging Clark with constant drunkenness, military incapacity, and a treasonable design of leading a military expedition down the Mississippi against Spain. Wilkenson was entirely successful; he was appointed Indian commissioner in Clark's place, and the latter was relieved of his command. Disappointed at his country's ingratitude, Clark spent the rest of his life near Louisville in retirement, dying on Feb. 13, 1818. Historical research in recent years has exposed Wilkenson's perfidy, and emphasized the importance of Clark's exploits. His most ardent supporters have even called him "the Washington of the West."

BIBLIOGRAPHY.—The *George Rogers Clark Papers, 1771-1783*, ed. J. A. James, are contained in vol. viii. and ix. of the *Illinois Historical Collections* (Springfield, 1912 and 1926). Clark's own narrative of his campaigns is published in *The Captive of Old Vincennes* (Indianapolis, 1927), ed. M. M. Quaife. The best biography is Temple Bodley's *George Rogers Clark: His Life and Public Services* (Boston, 1926). See also W. H. English, *Conquest of the Country North-west of the River Ohio, 1778-1783* (1896), and the *Mississippi Valley Historical Review* for Sept. 1924; Frederick Palmer, *Clark of the Ohio: A Life of George Rogers Clark* (1929).

CLARK, JOHN BATES (1847-), American economist, was born at Providence, R. I., Jan. 26, 1847. He was educated at Brown university, Amherst college, Heidelberg and Zurich and appointed professor of political economy at Carleton college, Minn. in 1877. Thereafter he served as professor at Smith college, Amherst college and Columbia university, retiring in 1923. From 1895 he was an editor of the *Political Science Quarterly* and director of the division of economics and history for the Carnegie endowment for international peace (1911-23).

Among his works are: *The Philosophy of Wealth* (1885); *The Distribution of Wealth* (1899); *The Control of Trusts* (1901), enlarged ed. with J. M. Clark (1912); *The Problem of Monopoly* (1904); *Essentials of Economic Theory as Applied to Modern Problems of Industry and Public Policy* (1907).

CLARK, JOSIAH LATIMER (1822-1898), English engineer and electrician, was born on March 10, 1822, at Great Marlow, Bucks. In 1848 he became assistant engineer at the Menai Straits bridge under his elder brother Edwin (1814-94), the inventor of the Clark hydraulic lift graving dock. Two years later, when his brother was appointed engineer to the Electric Telegraph Company, he again acted as his assistant, and subsequently succeeded him as chief engineer. In 1854 he took out a patent "for conveying letters or parcels between places by the pressure of air and vacuum," and later was concerned in the construction of a large pneumatic despatch tube between the general post office and Euston station, London. He also experimented on the propagation of the electric current in submarine cables, and in 1859 he was a member of the committee which was appointed by the Government to consider the numerous failures of submarine cable enterprises. Latimer Clark paid much attention to the subject of electrical measurement, and besides designing various improvements in method and apparatus and inventing the Clark standard cell, he took a leading part in the movement for the systematization of electrical standards, which was inaugurated by the paper which he and Sir C. T. Bright read on the question before the British Association in 1861. With Bright also he devised improvements in the insulation of submarine cables. He was a member of several firms engaged in laying submarine cables, in manufacturing electrical appliances, and in hydraulic engineering. He died in London on Oct. 30, 1898. His chief works are: *Electrical Measurement* (1868); and, with R. Sabine, *Electrical Tables and Formulae for Operators in Submarine Cables* (1871).

CLARK, THOMAS (1801-1867), Scottish chemist, was born at Ayr on March 31, 1801, and died at Glasgow on Nov. 27, 1867. He was professor of chemistry at Marischal college, Aberdeen, and is best known for his process for softening hard waters and his water tests, patented in 1841.

CLARK, WILLIAM (1770-1838), American soldier and explorer, the youngest brother of George Rogers Clark, was born

in Caroline county, Va., but early removed to Kentucky. He entered the U.S. army as lieutenant of infantry in 1792, and served under Gen. Anthony Wayne against the Indians in 1794. In 1803-06, with Meriwether Lewis, he commanded the famous exploring expedition from St. Louis to the mouth of the Columbia river and return, the first expedition to cross the continent within the limits of the United States. He was territorial governor of Missouri from 1813 to 1820, and superintendent of Indian affairs at St. Louis from 1822 until his death in 1838.

See the *Original Journals of the Lewis and Clark Expedition* (1905), edited by R. G. Thwaites, the best of several editions of the leader's journals; George Bird Grinnell, *Trails of the Pathfinders* (1911); "William Clark's Journal of General Wayne's Campaign, 1793-1794," *Mississippi Valley Hist. Rev.*, vol. i. p. 413-443 (Cedar Rapids, Iowa, 1914); and Floyd Duckworth Wells, *The Work of the Indian Agents in the Louisiana Purchase, 1804-1820* (St. Louis, Mo., 1926).

CLARK, WILLIAM GEORGE (1821-1878), English classical and Shakespearian scholar, was born at Barford Hall, Darlington, in March 1821 and died at York on Nov. 6, 1878. In 1853 Clark had taken orders, but left the church in 1870 after the passing of the Clerical Disabilities Act, of which he was one of the promoters. He established the *Cambridge Journal of Philology*, and co-operated with B. H. Kennedy and James Riddell in the production of the well-known *Sabinae Corolla*. The work by which he is best known is the *Cambridge Shakespeare* (1863-66), containing a collation of early editions and selected emendations, edited by him at first with John Glover and afterwards with W. Aldis Wright. *Gazpacho* (1853) gives an account of his tour in Spain; his visits to Italy at the time of Garibaldi's insurrection, and to Poland during the insurrection of 1863, are described in *Vacation Tourists*, ed. F. Galton, i. and iii.

See H. A. J. Munro in *Journal of Philology* (viii., 1879); also notices by W. Aldis Wright in *Academy* (Nov. 23, 1878); R. Burn in *Athenaeum* (Nov. 16, 1878); *The Times* (Nov. 8, 1878); *Notes and Queries*, 5th series, x. (1878), p. 400.

CLARKE, ADAM (1762?-1832), British Nonconformist divine, was born at Moybeg, Co. Londonderry, Ireland, in 1760 or 1762. He completed his education at Kingswood school and in 1782 was appointed by Wesley minister to the Bradford (Wiltshire) circuit. He was a great preacher, and was three times (1806, 1814, 1822) chosen to be president of the conference. He served twice on the London circuit, the second period being extended considerably longer than the rule allowed, at the special request of the British and Foreign Bible Society, who had employed him in the preparation of their Arabic Bible. He found time in his busy life to study Hebrew and other Oriental languages, in order to qualify himself for the great work of his life, his *Commentary on the Holy Scriptures* (1810-26). In 1802 he published a *Bibliographical Dictionary* in six volumes, to which he afterwards added a supplement. He was selected by the Records Commission to re-edit Rymers's *Foedera*, a task which after ten years' labour (1808-18) he had to resign. He also wrote *Memoirs of the Wesley Family* (1823), and edited a large number of religious works. He died in London on Aug. 16, 1832.

His *Miscellaneous Works* were published in 1836, and a *Life*, by his son J. B. B. Clarke, appeared in 1833.

CLARKE, ALEXANDER ROSS (1828-1914), British geodesist, was born in Sutherlandshire on Dec. 16, 1828. He studied at the Royal Military academy, Woolwich, and in 1847 became a second-lieutenant in the Royal Engineers. In 1850 Clarke was posted to the Ordnance Survey at Southampton, and except for a break between 1851-54 he remained there until he retired in 1881.

When Clarke joined the Ordnance Survey the observations on the Principal Triangulation had just been completed, and he had the task of reducing and publishing the results. This was done in record time, and in 1858 appeared *Account of the Observations and Calculations of the Figure, Dimensions and Mean Specific Gravity of the Earth as Derived Therefrom*. Clarke was mainly responsible for a good deal of similar work carried out in co-operation with other countries. His work was remarkably accurate and rapid, considering the laborious methods of calculation and

reduction in use at the time. In a specially-designed room he tested and compared the standards of length used by other countries and by the Colonies, publishing his observations in *Comparison of the Standards of Length of England, France, Belgium, Prussia, India and Australia* (1866).

Clarke gave an account of the observations which connected the English and French triangulations under the title of *Extension of the Triangulation of Great Britain into France and Belgium* (1863). He was the author of *Abstracts of Spirit Levelling in England, Wales and Scotland* (1861), *Geodesy* (1880), a standard work on this subject, which has been translated into many languages, and a number of papers in scientific journals. He was a member of many learned societies and was awarded the Royal Medal of the Royal Society in 1887. He had been made a Companion of the Bath in 1870. In 1881 Clarke was ordered to hold himself ready for service in Mauritius and preferred to retire rather than sever his connection with the Ordnance Survey. He lived a secluded life until he died on Feb. 11, 1914.

CLARKE, SIR ANDREW (1824-1902), British soldier and administrator, son of Col. Andrew Clarke, of Co. Donegal, Ireland, governor of West Australia, was born at Southsea, England, on July 27, 1824, and educated at King's school, Canterbury. He entered the army in 1844 as second-lieutenant in the Royal Engineers. He was appointed to his father's staff in West Australia, but was transferred to be A.D.C. and military secretary to the governor of Tasmania; and in 1847 he went to New Zealand to take part in the Maori War, and for some years served on Sir George Grey's staff. He was then made surveyor-general in Victoria, took a prominent part in framing its new constitution, and held the office of minister of public lands during the first administration (1855-57). From 1864-73 he was director of works for the navy, being responsible for great improvements in the naval arsenals and fortifications at home and abroad. In 1873 he became governor of the Straits Settlements. From 1875-80 he was minister of public works in India; and on his return to England in 1881, he was first appointed commandant at Chatham and then inspector-general of fortifications (1882-86). He died on March 29, 1902. Both as a technical and strategical engineer and as an Imperial administrator Sir Andrew Clarke was one of the ablest and most useful public servants of his time.

CLARKE, SIR CASPAR PURDON (1846-1911), English art expert, was born in London on Dec. 21, 1846, and educated privately at Sydenham and Boulogne. In 1862 he was trained as an architect in the art schools at South Kensington. In 1865 he entered the Office of Works, and in 1867 was attached to the works department of the South Kensington museum. He travelled extensively for the museum, purchasing objects of art, and at the same time carried on his profession as an architect. In 1883 he became keeper of the India museum at South Kensington, in 1892 keeper of the art collections, in 1893 assistant-director, and in 1896 director. In 1905 he became director of the Metropolitan Museum, New York, resigning in 1910. He was knighted in 1902. He died in London on March 29, 1911.

CLARKE, CHARLES COWDEN (1787-1877), English author and Shakespearian scholar, was born at Enfield, Middlesex, on Dec. 15, 1787. His father, John Clarke, was a schoolmaster, among whose pupils was John Keats. Charles Clarke taught Keats his letters, and encouraged his love of poetry. He knew Charles and Mary Lamb, and afterwards became acquainted with Shelley, Leigh Hunt, Coleridge and Hazlitt. Clarke became a music publisher in partnership with Alfred Novello, and married in 1828 his partner's sister, Mary Victoria (1809-98), the eldest daughter of Vincent Novello. In the year after her marriage Mrs. Cowden Clarke began her valuable Shakespeare concordance, which was eventually issued in 18 monthly parts (1844-45), and in volume form in 1845 as *The Complete Concordance to Shakespeare, being a Verbal Index to all the Passages in the Dramatic Works of the Poet*. This work superseded the *Copious Index to . . . Shakespeare* (1790) of Samuel Ayscough, and the *Complete Verbal Index . . .* (1805-07) of Francis Twiss. Charles Cowden Clarke published many useful books, and edited the text for John Nichol's edition of the British poets; but his most important

work consisted of lectures delivered between 1834 and 1856 on Shakespeare and other literary subjects. Some of the more notable series were published, among them being *Shakespeare's Characters, chiefly those subordinate* (1863), and *Molière's Characters* (1865). In 1859 he published a volume of original poems, *Carmina Minima*. For some years after their marriage the Cowden Clarkes lived with the Novellos in London. In 1849 Vincent Novello with his wife removed to Nice, where he was joined by the Clarkes in 1856. After his death they lived at Genoa at the Villa Novello. They collaborated in *The Shakespeare Key, unlocking the Treasures of his Style . . .* (1879), and in an edition of Shakespeare or Messrs. Cassell, which was issued in weekly parts, and completed in 1868. It was reissued in 1886 as *Cassell's Illustrated Shakespeare*. Charles Clarke died on March 13, 1877, at Genoa, and his wife survived him until Jan. 12, 1898. Among Mrs. Cowden Clarke's other works may be mentioned *The Girlhood of Shakespeare's Heroines* (1850-52), and a translation of Berlioz's *Treatise upon Modern Instrumentation and Orchestration* (1856). See *Recollections of Writers* (1898), a joint work by the Clarkes containing letters and reminiscences of their many literary friends; and Mary Cowden Clarke's autobiography, *My Long Life* (1896). A charming series of letters (1850-61), addressed by her to an American admirer of her work, Robert Balmanno, was edited by Anne Upton Nettleton as *Letters to an Enthusiast* (Chicago, 1902).

CLARKE, EDWARD DANIEL (1769-1822), English mineralogist and traveller, was born at Willingdon, Sussex, on June 5, 1769, and educated at Tonbridge and Jesus college, Cambridge. In 1799-1803 he made an extended tour through the continent of Europe and afterwards to Egypt and Palestine. After the capitulation of Alexandria, Clarke was of considerable use in curing for England the statues, sarcophagi, maps, manuscripts, &c., which had been collected by the French savants. He returned home by way of Athens, Constantinople, Rumelia, Austria, Germany and France. On arriving in England Clarke made important donations to Cambridge university, including a colossal statue of the Eleusinian Ceres. He received the livings of Harlton and Eldham and near the end of 1808 was appointed to the professorship of mineralogy in Cambridge, then first instituted. The MSS. which he had collected in the course of his travels were sold to the Bodleian library. He was also appointed university librarian in 1817 and was one of the founders of the Cambridge Philological Society in 1819. He died in London on March 9, 1822. The following is a list of his principal works: *Testimony of Authors respecting the Colossal Statue of Ceres in the Public Library, Cambridge* (1801-3); *The Tomb of Alexander, a Dissertation on the sarcophagus brought from Alexandria, and now in the British Museum* (1805); *A Methodical Distribution of the Mineral Kingdom* (Lewes, 1807); *A Description of the Greek Marbles brought from the shores of the Euxine Archipelago and Mediterranean and deposited in the University Library, Cambridge* (1809); *Travels in Various Countries of Europe, Asia and Africa* (1810-19; 2nd ed., 1811-23). See Rev. W. Otter, *Life and Remains of E. D. Clarke* (London, 24).

CLARKE, SIR EDWARD GEORGE (1841-), English lawyer and politician, son of J. G. Clarke, of Moorgate street, London, was born on Feb. 15, 1841. In 1859 he became a writer for the India office, but resigned in the next year, and became a newspaper reporter. He obtained a Tancred law scholarship in 1861, and was called to the bar at Lincoln's Inn in 1864. He joined the Inner Temple circuit, became Q.C. 1880, and a bencher of Lincoln's Inn 1882. He appeared, among other cases, as counsel for Patrick Aulton in the Penge murder case (1877) for Mrs. Bartlett (1886), for Sir W. Gordon-Cumming in his slander action (in which Edward VII., then Prince of Wales, gave evidence), and for Jameson in 1896. He was knighted in 1886. He was returned Conservative member for Southwark at a by-election early in 1900, but failed to retain his seat at the general election which followed a month or two later; he found a seat at Plymouth, however, which he retained until 1900. He was solicitor-general under the Conservative administration of 1886-92, but declined office under the Unionist government of 1895 when the law officers of the crown were debarred from private practice. The most remarkable, perhaps, of his speeches in the House of Commons was his reply to Mr. Gladstone on the second reading of the Home Rule Bill in 1893. In 1899 he resigned his seat on the question of the

government's South African policy. At the general election in 1906 he was returned at the head of the poll for the city of London, but he offended a large section of his constituents by a speech against tariff reform in the House of Commons on March 12, and shortly afterwards he resigned his seat on grounds of health. He retired from the bar in 1914.

He published a *Treatise on the Law of Extradition* (4th ed. 1903), four volumes of his political and forensic speeches; *The New Testament: The Authorized Version Corrected* (1913); *The Book of Psalms: the Prayer Book Version Corrected* (1915); and his autobiography, *The Story of My Life* (1918).

CLARKE, JAMES FREEMAN (1810-1888), American preacher and author, was born in Hanover (N.H.) on April 4, 1810. He graduated at Harvard college in 1829, and at the Harvard divinity school in 1833. He was then ordained as minister of a Unitarian congregation at Louisville (Ky.), and soon threw himself heart and soul into the national movement for the abolition of slavery, though he was never a "radical abolitionist." In 1839 he returned to Boston, where he and his friends established (1841) the "Church of the Disciples," which brought together a body of men and women active and eager in applying the Christian religion to the social problems of the day. Of this church he was the minister from 1841-50 and from 1854 until his death. He was also secretary of the Unitarian Association and in 1867-71 professor of natural religion and Christian doctrine at Harvard. From 1836-39 he was editor of the *Western Messenger*, a magazine which is now of value to collectors because it contains the earliest printed poems of Ralph Waldo Emerson, who was Clarke's personal friend. Most of Clarke's earlier published writings were addressed to the immediate need of establishing a larger theory of religion than that espoused by people who were still trying to be Calvinists, people who maintained what a good American phrase calls "hard-shelled churches." But it would be wrong to call his work controversial. In the great moral questions of his time he was a fearless and practical advocate of the broadest statement of human rights. He published but few verses, but at the bottom he was a poet. He was a diligent and accurate scholar, and among the books by which he is best known is one called *Ten Great Religions* (2 vols., 1871-83). Few Americans have done more than Clarke to give breadth to the published discussion of the subjects of literature, ethics and religious philosophy. Among his books are *Orthodoxy* (1866); *Every-Day Religion* (1886) and *Sermons on the Lord's Prayer* (1888). He died at Jamaica Plain (Mass.) on June 8, 1888.

His *Autobiography, Diary and Correspondence* edited by Edward Everett Hale, was published in 1891. (E. E. H.)

CLARKE, MARCUS ANDREW HISLOP (1846-1881), Australian author, was born in London on April 24, 1846, and died at Melbourne on Aug. 2, 1881. He emigrated about 1863 to Australia, where his uncle, James Langton Clarke, was a county court judge. He was at first a clerk in the Bank of Australasia, and then learned farming at a station on the Wimmera river, Victoria. He was already writing stories for the *Australian Magazine*, when in 1867 he joined the staff of the Melbourne *Argus*. He also became secretary (1872) to the trustees of the Melbourne public library, and later (1876) assistant librarian. He founded in 1868 the Yorick club, which soon numbered among its members the chief Australian men of letters. The most famous of his books is *For the Term of his Natural Life* (Melbourne, 1874), a powerful tale of an Australian penal settlement, which originally appeared in serial form in a Melbourne paper.

See *The Marcus Clarke Memorial Volume* (Melbourne, 1884), containing selections from his writings with a biography and list of works, edited by Hamilton Mackinnon.

CLARKE, MARY ANNE (c. 1776-1852), mistress of Frederick, duke of York, second son of George III., married before she was 18 a Mr. Clarke, a stonemason, whom she soon left. She became in 1803 the mistress of the duke of York, then commander-in-chief. The duke's promised allowance was not regularly paid, and to escape her financial difficulties Mrs. Clarke trafficked in her protector's position, receiving money from various promotion-seekers, military, civil and even clerical, in return

for her promise to secure them the good services of the duke. These proceedings caused a public scandal, and in 1809 Col. Wardle, M.P., brought eight charges of abuse of military patronage against the duke in the House of Commons, and a committee of inquiry was appointed, before which Mrs. Clarke herself gave evidence. The Duke of York was shown to have been aware of what was being done, but to have derived no pecuniary benefit himself. He resigned his appointment as commander-in-chief and terminated his connection with Mrs. Clarke, who subsequently obtained from him a considerable sum in cash and a pension as the price for withholding the publication of his numerous letters to her. Mrs. Clarke died at Boulogne on June 21, 1852.

See Elizabeth Taylor, *Authentic Memoirs of Mrs. Clarke* (1809); W. Clarke, "Life of Mrs. M. A. Clarke," in the *Annual Register*, vol. li, p. 61.

CLARKE, SAMUEL (1675-1729), English philosopher and divine, son of Edward Clarke, an alderman, who for several years was parliamentary representative of the city of Norwich, was born on Oct. 11, 1675, and educated at the free school of Norwich and at Caius college, Cambridge. The philosophy of Descartes was the reigning system at the university; Clarke, however, mastered the new system of Newton, and contributed to its extension by publishing in 1697 a Latin version of the *Traité de physique* of Jacques Rohault, which was used as a text-book till supplanted by the treatises of Newton himself. Having taken holy orders, he became chaplain to John Moore (1646-1714), bishop of Norwich, who later presented him to the rectory of Drayton near Norwich. He subsequently became chaplain in ordinary to Queen Anne, who in 1709 presented him to the rectory of St. James, Westminster, in which year he became a Doctor of Divinity. As Boyle lecturer, he dealt in 1704 with the *Being and Attributes of God*, and in 1705 with the *Evidences of Natural and Revealed Religion*. These lectures, first printed separately, were afterwards published together under the title of *A Discourse concerning the Being and Attributes of God, the Obligations of Natural Religion, and the Truth and Certainty of the Christian Revelation, in opposition to Hobbes, Spinoza, the author of the Oracles of Reason, and other Deniers of Natural and Revealed Religion*. During 1712 he published his celebrated treatise on *The Scripture Doctrine of the Trinity*. It is divided into three parts. The first contains a collection and exegesis of all the texts in the New Testament relating to the doctrine of the Trinity; in the second the doctrine is set forth at large, and explained in particular and distinct propositions; and in the third the principal passages in the liturgy of the Church of England relating to the doctrine of the Trinity are considered. This book involved Clarke in some trouble in the Convocation, which subsequently blew over.

In 1715 and 1716 he had a discussion with Leibniz relative to the principles of natural philosophy and religion, which was at length cut short by the death of his antagonist. A collection of the papers which passed between them was published in 1717 (cf. G. v. Leory, *Die philos. Probleme in dem Briefwechsel Leibniz und Clarke*, Giessen, 1893). He died on May 17, 1729.

See W. Whiston, *Historical Memoirs*, and the preface by Benjamin Hoadly to *Clarke's Works* (1738-42).

CLARKE, THOMAS SHIELDS (1860-1920), American artist, was born in Pittsburgh (Pa.), on April 25, 1860, and graduated at Princeton in 1882. He was a pupil of the Art Students' League, New York, and of the École des Beaux Arts, Paris, under J. L. Gérôme; later he entered the atelier of Dagnan-Bouveret, and, becoming interested in sculpture, worked for a while under Henri M. Chapu. As a sculptor, he received a medal of honour in Madrid for his "The Cider Press," now in Golden Gate Park, San Francisco, Calif., and he made four caryatids of "The Seasons" for the Appellate Court House, New York. He designed an "Alma Mater" for Princeton university, and a model is in the library. Among his paintings are his "Night Market in Morocco" (Philadelphia Art Club), for which he received a medal at the International Exposition in Berlin in 1891, and his "A Fool's Fool," exhibited at the Salon in 1887 and now in the collection of the Pennsylvania Academy of Fine Arts, Philadelphia. He died in New York city on Nov. 15, 1920.

CLARKE, WILLIAM BRANWHITE (1798-1878), British geologist, was born at East Bergholt, in Suffolk, on June 2, 1798. He received his early education at Dedham grammar school and in 1817 entered Jesus college, Cambridge; he was ordained, and became curate of Ramsholt, Suffolk. In 1839, after a severe illness, he left England for New South Wales, mainly with the object of benefiting by the sea voyage. He remained there, accepted a clerical charge, and came to be regarded as the "Father of Australian Geology." In 1841 he discovered gold, being the first explorer who had obtained it *in situ* in the country, finding it both in the detrital deposits and in the quartzites of the Blue mountains, and he then declared his belief in its abundance. In 1849 he made the first actual discovery of tin in Australia and in 1859 he made known the occurrence of the diamond. He was also the first to indicate the presence of Silurian rocks, and to determine the age of the coal-bearing rocks in New South Wales. In 1869 he announced the discovery of remains of *Dinornis* in Queensland. He was a trustee of the Australian museum at Sydney and an active member of the Royal Society of New South Wales. In 1860 he published *Researches in the Southern Gold-fields of New South Wales*. He was elected F.R.S. in 1876, and in the following year was awarded the Murchison medal by the Geological Society of London. He died near Sydney on June 17, 1878.

CLARKSBURG, a city in the heart of the coal, oil and gas fields of West Virginia, U.S.A., on the West Fork river at the mouth of Elk creek; the county seat of Harrison county. It is on Federal highways 19 and 50, and is served by the Baltimore and Ohio Railroad. The population in 1920 was 27,869 (88.5% native white), and was 28,866 in 1930 by the Federal census. The city lies on a plain 1,100 ft. above sea-level, surrounded by beautiful hills, in a rich agricultural and grazing, as well as mining, region. It has a large wholesale and retail trade. Coal, natural gas and electric power are available for industrial uses, and the city has numerous manufactures, with an output in 1925 valued at \$15,949,281. The leading products are glass of various kinds, pottery, china, porcelain, earthenware, carbon electrodes, tin-plate, tin cans, zinc spelter, boxes, caskets, bricks, tiles and machinery.

Clarksburg was settled in 1765, and was incorporated in 1785 by the general assembly of Virginia. It was named after George Rogers Clark. In 1917 the towns of Broad Oaks, Stealey Heights, Adamston and North View and several adjoining districts were consolidated with the old city of Clarksburg, which in 1910 had a population of 9,201. A new charter was adopted in 1921, establishing a council-manager form of government. In the next five years contagious diseases were practically eliminated, infant mortality was reduced far below the average for the country, a municipal playground system was developed, the best record in the State was established for the enforcement of the liquor laws, loss by fire was cut to a very low figure, public improvements costing \$1,200,000 were made and the city debt was reduced by over \$500,000.

Clarksburg was the birthplace of "Stonewall" Jackson, of Nathan Goff and of John W. Davis.

CLARKSDALE, a city of north-western Mississippi, U.S.A., on Federal highway 61, 75 m. S. by W. of Memphis; the county seat of Coahoma county. It is served by the Illinois Central railway. In 1900 the population was 1,773; in 1920, 7,552, of whom 4,392 were negroes; and 10,043 in 1930 by the Federal census. It is an important cotton and mule market and has cotton-seed oil mills and other factories. The city was founded about 1830, and was first incorporated in 1882.

CLARKSON, THOMAS (1760-1846), English anti-slavery agitator, was born on March 28, 1760, in Wisbech, Cambs., the son of a schoolmaster. He was educated at St. Paul's school and St. John's college, Cambridge. Clarkson was first drawn to the subject of slavery by reading Benezet's *Historical Survey of New Guinea* (for a prize essay in 1785) on the question set by the vice-chancellor of the university: "Is it right to make men slaves against their will?" The English translation of the Latin of this prize essay, published in 1786, brought him into touch with William Dillwyn, Joseph Wood and Granville Sharp, and soon a com-

mittee of 12 was formed to do all that was possible to effect the abolition of the slave trade. Meanwhile Clarkson gained the sympathy of Wilberforce, Whitbread, Pitt, Grenville, Fox and Burke, and spent his days in travelling from port to port, gaining a mass of evidence which was partly embodied in his *Summary View of the Slave Trade, and the Probable Consequences of its Abolition*. In May 1788 Pitt introduced a parliamentary discussion on the subject, and Sir W. Dolben brought forward a bill, which was passed in the House of Commons on June 18, providing that the number of slaves carried in a vessel should be proportional to its tonnage. In the same year, Clarkson published an *Essay on the Impolicy of the Slave Trade*, but could only get nine men, personally acquainted with the facts of the trade, to promise to appear before the Privy Council. Wilberforce and the committee, however, had obtained other witnesses, and in May 1789 the former led a debate on the subject in the House of Commons, in which he was seconded by Burke and supported by Pitt and Fox.

At the outbreak of the French Revolution, Clarkson hoped that the French would sweep away slavery with other abuses; but the hope was vain, and after six months in Paris during which he enlisted the sympathies of Necker, Mirabeau and the Marquis de la Fayette, he returned to England and to his laborious search for further witnesses of the slave traffic. After his health gave way in 1794, Clarkson laid aside active work for writing, publishing in 1806 *Portraiture of Quakerism*, and, two years later, the *History of the Rise, Progress and Accomplishment of the Abolition of the Slave Trade by the Brit. Parliament*. The bill for the abolition had become law in 1807, and finally, in 1815, British diplomacy secured the condemnation of the trade by the other Great Powers. When the question of practical measures for its abolition was unsuccessfully discussed at the Congress of Aix-la-Chapelle in 1818, Clarkson personally presented an address to the emperor, Alexander I., who communicated it to the sovereigns of Austria and Prussia. In 1823 the Anti-Slavery Society was formed with Clarkson as its vice-president.

From this date until his death at Ipswich on Sept. 26, 1846, his chief works were *Thoughts on the Necessity for Improving the Condition of the Slaves in the British Colonies* (1823), and *American Slavery* (1845). His *Memoirs of William Penn* had appeared in 1813. See T. Elmes, *Thomas Clarkson* (1854).

CLARKSVILLE, a city of northern Tennessee, U.S.A., on the Cumberland river at the mouth of the Red river, 50m. N.W. of Nashville; the county seat of Montgomery county. It is on Federal highway 41, and is served by the Louisville and Nashville and the Tennessee Central railways and by river steamers. The population in 1920 was 8,110; 1930, 9,242. It is in a region of great scenic beauty, at the centre of the dark tobacco belt. It has a very large trade in both leaf and manufactured tobacco, and in pure-bred live stock, dairy products and strawberries. There are flour-mills, a large snuff factory and other industries. Clarksville was settled in 1780, was named after Gen. George Rogers Clark and was chartered as a city in 1850. Dunbar's Cave, a picturesque and interesting cavern, is 3m. from the city.

CLASS commonly denotes any group or set of people or things. This is clear in the use of the term with reference to school and examination groupings. When applied to social groups the term is sometimes used in the same way, and sometimes in the sense of "the higher or wealthier class" (in contrast with the mass of the people). In logic, and in science generally, the term *class* is not synonymous with any limited *group*. It means a *kind*; and a kind may be, but is not usually, a limited group. In any case this reference is not to number at all. A class may be known only through a single specimen (as sometimes happens in palaeontology) or it may consist of an endless stream of individuals or groups of individuals. In biology this term *class* has a definite or fixed place in the classificatory scheme—it is one of the kinds into which a "kingdom" is divided, "kingdom" being the most comprehensive class in the biological series.

CLASS DAY, in American colleges and universities a day on which the members of the senior or graduating class celebrate the completion of their courses. The ceremony may take the

form of a literary programme involving the reading of the class history or the class poem, the delivery of the class oration or the presentation of the class play; it may include, too, the planting of the class ivy or the class tree or the burning of books in a huge bonfire to signify liberation from class-room routine. Formal presentation of a memorial gift to alma mater, athletic contests, campus singing, receptions, banquets and other forms of entertainment reflecting the traditions of the institution may also characterize the event.

CLASSICAL EDUCATION. In the universities of Great Britain archaeology, anthropology, numismatics, epigraphy, psychology, philology and geography are recognized as essential to the classical scholar who would understand and describe clearly conditions of life in the ancient civilizations. Western Europe has learned to realize the measure of its debt to Greece and to estimate the nature of the legacy it has received from Imperial Rome. The precision of classical literature leads to a sense of proportion, a standard of values, a respect for the truth of words, and accuracy of thought. In the principal secondary schools classical studies are not losing ground (*see* PUBLIC SCHOOLS). As historical links exist with university foundations, the great public schools conserve the best traditions of classical scholarship. In the ordinary secondary schools Latin is taught as one of several competing subjects. Of new methods in use the following is one of the most interesting and most original.

The Direct Method.—The direct method of teaching foreign languages aims at connecting the foreign word, phrase or sentence directly with a thing, act or thought, without the intervention of English. When a certain number of words have been learned, new ones are explained by a paraphrase in the same language; and in the final stage, the literature is read and discussed in the original.

A working system has been devised by which this method can be applied to Latin and Greek. Time is saved, because the whole lesson is taken up with the language, attention is kept, because the language used is real to us instead of artificial; understanding is easy, because what we do or see, explains what is said. In proportion as we exclude English words from our minds, we come to think in the language, and a feeling for its idioms and turns of speech is soon developed. Since the vocabulary used is simple and deals with every-day and familiar life, the attention can be exercised on the peculiar inflections which distinguish the ancient languages.

Grammar is learned after use, not before, and is therefore less irksome. Short exercises are used, to illustrate grammar; they do no harm if they come in their proper place (after use) and in due proportion.

With the reading book, from the very first all is read aloud and explained in the same language, the explanations being written and learned. English is never used unless it cannot be helped. When the pupils are fit to read an author, they know enough to dispense with English. Formal translation from English into Latin or Greek, the most difficult of all exercises, is reserved for the last two years of school life. Whoever does not understand must ask. No one is blamed for not understanding; all are blamed for not asking.

In the reading lesson every line of the matter is read aloud; and very often the mere manner of reading shows whether the text has been understood, and if it has not, it can be explained simply by correct reading. By reading the memory is filled, the ear is taught, the taste is trained; the language, in short, is learned in the most effective way. So much so that verses of all sorts, lyrics included, are written with ease by imitation. But the real merit of this method lies in its effect on the learner. From the first stage to the last, the learners are willing to learn, and happy in learning. (C. Br.; W. H. D. R.)

The United States.—Classical education in the United States began with the founding of Harvard college and the Boston Latin school in about 1638. Following the English model (probably Cambridge) the only requirement for entrance to Harvard was the ability to read and speak Latin, and some knowledge of Greek forms, and this was also the aim of the Latin school. All lectures were in Latin, the curriculum consisted almost wholly of the

classics and students were required to speak Latin on the campus. The subsequent progress of classical education has been divided roughly into three periods: the pre-revolutionary period, the period to the close of the Civil War, and the modern period.

During the first period admission requirements remained much the same, as at Harvard, even arithmetic was not required until 1693, and then not universally. In the colleges the classics remained supreme, although arithmetic, geography and anatomy were included in the curriculum of William and Mary in 1693, and physics in that of Yale in 1701. Also the forerunner of the University of Pennsylvania, under the influence of Benjamin Franklin, made considerable provision for science, and an impressive programme in science and history was announced by Columbia in 1754, which, however, as not adhered to.

The middle period was one of great educational expansion. Many new colleges and secondary schools were founded, and the States began to make provision for higher public education in the State universities. Public high schools also began to multiply. The curricula of the colleges were greatly extended, and the appearance of new subjects in the requirements for entrance involved provision for them in the fitting schools. At first Greek and Latin, later Latin alone, were obligatory on all candidates for degrees, and while in some academies, notably those for girls, and in the State universities, the tendency was to greater freedom, still the general tone of education was cultural, interpreted as classical.

The modern period has been one of revolution, both in ideals and practices. The carrying out of the theory of universal education, and the rapid growth of industrialism demanded greater provision for vocational and scientific training. The public high schools still clung closely to the classical tradition but they showed the new influence in the great broadening of their curriculum. Where this was not done, vocational and trade schools discarded the classics for a more immediately practical training. In higher education, either separate scientific and technical schools were established, or increased provision was made for science in the colleges and universities, and modern languages and the social sciences vied with the natural sciences in pressing their claims.

Room for the new subjects could only be obtained at the expense of the classics. The first to be seriously affected was Greek, which, though vigorously defended, had by 1928 been eliminated almost entirely from the curriculum of the secondary schools, and was studied by very few undergraduates in college. Latin also was severely curtailed and at one time seemed likely to go the way of Greek. Since the World War, however, there has been some reaction in favour of Latin in the colleges and it has continued to hold a large place in the schools, partly because it is still an important requirement for entrance to college. It was estimated that over 1,000,000 pupils were studying Latin in the schools in 1928. It is not, however, the Latin of former days. Under the attacks of the new psychology and the advocates of practical studies the teaching of Latin, which formerly had been largely a mechanical preparation for entrance examinations, has now been adapted rather to the immediate needs of the pupils studying it. In 1920 the general education board arranged with the American Classical League to conduct an investigation of the classics (chiefly Latin) in the secondary schools. In the report, published in 1924, the aims of the teaching of Latin were set forth as follows: to read and understand Latin; to increase the pupil's ability to understand the Latin element in English, and to read, speak and write English; to develop historical and cultural background, correct mental habits and right attitudes towards social situations; to increase the ability to learn foreign languages; and to give an elementary knowledge of the principles of language structure. In the furtherance of these aims extensive recommendations were made as to curriculum and method of teaching. These have been very widely adopted and the text-books are rapidly being reconstructed to carry them out. As a result the outlook is bright for continued support of Latin, particularly in the secondary schools, as an important element in American education. (G. L.)

France.—In France during the greater part of the 19th century, the position of classics in secondary schools was supreme. They alone led to the baccalaureate:—sole entrance to the uni-

versities and the liberal professions. Towards the end of the century, a strong movement in favour of modern languages and science arose. In 1898 a parliamentary committee was appointed to inquire into the subject. They reported in 1899, but it was not till 1902 that their conclusions were embodied in the establishment of four alternative courses, a full classical, a Latin-modern languages, a Latin-science and a purely modern course, all of which led to the university. These courses remained unchanged for nearly 20 years, and during that period the classical candidates for the baccalaureate, who in 1904 numbered 3,337, fell to 2,775 in 1924. The Latin-modern rose from 1,217 to 5,964, the Latin-science from 2,229 to 5,241 and the science-modern languages from 2,742 to 5,241. Thus, while Greek declined, the students taking Latin increased more than twofold and amounted to over 70% of the candidates.

The World War brought its aftermath of discussion. In 1922 M. Bérard, the minister of public instruction, proposed to make Latin and Greek obligatory in the earlier stages, and to cut down the courses of two (classical or modern). A bitter struggle followed, in which the majority of expert opinion was against him. None the less, in May 1923 the President of the republic issued a decree embodying the proposals of M. Bérard, and requiring a certificate of proficiency in Latin and Greek from all future candidates for the baccalaureate. A year later the Ministry fell and was replaced by a Radical one. The two courses have been maintained, but classics are no longer obligatory for all, though as the curricula of the girls' schools have now been assimilated to those of the boys, a classical education is equally open to the former.

Germany.—In Germany up to the end of the 19th century, classics were likewise supreme. The full classical school, the *Gymnasium*, was with one or two exceptions the sole avenue to the university and liberal professions. In 1890, at the instance of the Kaiser, a conference was called in Prussia. Its conclusions, largely embodied in the curricula of 1892, reduced the number of hours given to classics and dethroned the latter in favour of the mother tongue, while the universities were thrown open to pupils from the *Realgymnasium* (Latin-modern school) and to a large extent to those from the *Oberrealschule* (modern studies school). Similar reforms had already been adopted by other German states. The next outstanding feature was the founding of *Reformgymnasien*, where the first language was French, Latin not being introduced till the fourth and Greek till the sixth year, both being taught intensively. This type was largely adopted in Prussia before the war. Classical studies have been open to girls since 1904, but the number taking them has not been very great. For education since the war, no statistics are available, but according to one authority, "the desertion of schools with Latin as a central subject is general." Others are less pessimistic and the prevailing opinion seems to be that the *Reformschulen* will ultimately be the future type of German classical education.

Italy.—Of the other European countries, the most interesting one from the classical standpoint of view is Italy. Here, thanks to the reforms of Gentile, there has been a strong reaction in favour of classics, and by the royal decrees of May and Nov. 1922, classical studies have been strengthened in the higher schools not only of the purely classical but also of the scientific type. Latin in fact is now obligatory in all secondary schools. Room for this increase has been found by cutting down the number of subjects and reducing the time given to mathematics; the main object of the reform being to replace the former encyclopaedic aim of the school by a cultural one based on direct knowledge of the classics. Latin is also a principal subject in the girls' high schools.

Belgium.—In Belgium again the position of classics appears to have improved. A committee was appointed after the War to consider the reform of the school syllabuses and the position of Greek. As a result, classics have been maintained in the *Athénées Royales* (high schools) and further Greek and Latin can be studied in those *écoles moyennes*, which are not within convenient distance of an *athénée*.

Norway.—In Norway, likewise, the classics have recovered ground. In 1896 Greek was entirely banished from secondary education; to-day it is included in one section of the higher schools (*gymnasia*), and can be studied by girls as well as boys.

Czechoslovakia.—The republic of Czechoslovakia has largely maintained the previous types of education, which were on German lines and as the system is co-educational, classical or Latin studies are equally open to girls.

Sweden.—In Sweden classics seem to have somewhat lost ground. The pupils following a full classical or Latin course, who ten years ago were in a majority, are now outnumbered by those taking modern studies. (C. Br.; W. H. D. R.)

Latin American Countries.—In Latin American countries less attention is given to study of classical languages than in other countries whose culture is derived from the classical heritage. In the first place secondary schools in most Latin American countries were established at a time of reaction against schools maintained by the teaching orders which had emphasized the classical basis in secondary education. Secondly, universities have consisted in the main of loosely associated faculties for professional preparation and are only just beginning to permit the study of liberal art subjects either in existing faculties of philosophy as in Buenos Aires, or in newly created faculties as in Santiago. In these the study of the classics may find encouragement in time. Thirdly, the secondary school curriculum has developed by an accretion of subjects and unlike the development in European countries and the United States, little provision has been made for options or for differentiated courses. Consequently, when the list of subjects to be carried became too burdensome, a solution was found by dropping those subjects, especially Latin, which the pupils found too difficult and whose utility was not recognized by the parents.

The situation in general may be illustrated from the practices of some of the leading Spanish American countries. In the Argentine a movement to make Latin an optional subject began as early as 1870 and was realized in 1886; in 1891 proposals began to be made to drop it and by 1901 it disappeared entirely except in three schools that enjoy special privileges of autonomy. Greek had disappeared as early as 1863. In Chile Latin ceased to be required for graduation from a secondary school in 1877 and gradually disappeared. In 1925 an inquiry elicited the opinion that room should be found in certain schools for the study of Latin with or without Greek. It is significant to note, however, that all students in the Instituto Pedagógico, the institution for training secondary school teachers, must take Latin, if they wish to become specialists in Spanish or any modern foreign language. In Uruguay Latin grammar was taught in the first two years of the secondary school course in 1889 but was dropped in 1909. Latin is required in Mexico of students who plan to enter the faculty of law of the university.

In Brazil the exception to the general practice may be found, for here Latin is required for four years of the six year secondary course and Greek survives in some schools on an optional basis.

The secondary school situation is reflected in the universities. The general absence of liberal arts faculties has been noted. The small number of professors of Latin or of Greek is to be found at the Universities of Buenos Aires and La Plata in the Argentine, in the Instituto Pedagógico of the University of Chile and in the University of Concepción in Chile, and in the private Colegio Mayor de Nuestra Señora del Rosario in Colombia. Latin, if not Greek, is still cultivated by the ecclesiastical orders and it is under the direction of their members that those who are interested in the classics may pursue their studies beyond the level of the secondary schools. (I. L. K.)

CLASSICS. "What need to speak of Democritus? . . . Who does not place this philosopher above Cleanthes, Chrysippus, and the others of later times? These appear to me to be fifth class as compared with him" (*qui mihi cum illo collati quintae classis videntur*). Thus Cicero, *Academics* ii. 23, 73. The expression "fifth class," natural and familiar as it sounds to a modern ear, has an interesting history. Among the constitutional reforms as-

cribed to Servius Tullius, the sixth king of Rome, was the division of the citizens into five *classes* according to the amount of their property as determined from time to time by a census. Hence the fifth *classis* denoted the lowest class of citizen from the point of view of wealth. It appears from Aulus Gellius, vi. 13, that the term *classicus* was applied only to the first or highest *classis*: "Not all those who were enrolled in the five classes were called *classici*, but only the men of the first class, who were rated at 125,000 *asses* or more. 'Below class' was the appellation given to those of the second or other classes rated at a lower sum. . . . This I have briefly noted because apropos of M. Cato's speech in support of the Voconian law the question is often asked what is meant by *classicus* and what by 'below class.'" When or by whom the term was first used in a metaphorical sense to denote an order of merit, we do not know. This extension is already implied in the *quintae classis* of Cicero. But the first extant example of *classicus* to denote the highest order of literary merit seems to be Aulus Gellius (2nd century A.D.) xix., 8, 15. Julius Caesar in his treatise *De Analogia* had laid down the doctrine that *quadrigae* (in the plural), even of a single chariot, is the only correct use, and conversely that *harena* (sand) is only used correctly in the singular. Gellius narrates a conversation on the matter with M. Cornelius Fronto, who supports the opinion of Caesar, and concludes with the words: "Now go, and when you have time see if you can find *quadrigae* in the singular, or *harena* in the plural, written by any of the elder orators and poets—I mean, by one who is a *classicus* and *assiduus* writer, not one who is *proletarius*." *Assiduus* seems to have been applied more generally to members of the wealthier classes, being equivalent to *locuples* and indicating a person of property (Cic. *Rep.* ii. 22-40; cf. Aul. Gell. xvi. 10). *Proletarii*, on the other hand, were the poorest citizens who contributed nothing to the state but their offspring (*proles*); (cf. Aul. Gell. l.c., Cic., *Rep.* ii. 22-40). In modern times the word "classic" is in common use of any author who has stood the assize of the centuries, or even of one who in his own time is classed with those who have: Macaulay, *Boswell's Life of Johnson*: "What a singular destiny has been that of this remarkable man! To be regarded in his own age as a classic and in ours as a companion!" But the term "classics" has been long and widely used to denote more especially the literatures of ancient Greece and Rome, and in that sense it is employed here.

THE LITERATURE OF GREECE

Commencing with Homer, ancient Greek literature may be considered as extending down to Justinian (A.D. 527), thus covering a period of something like 14 centuries. Within this period it is usual to distinguish (1) the Classical period extending from Homer to the death of Alexander (323 B.C.), (2) the Alexandrine period from 323 B.C.—A.D. 100, (3) the Post-Alexandrine period A.D. 100-529. The Byzantine period from 529 to the capture of Constantinople by the Turks produced no Greek literature of first-rate importance.

The unique feature of Greek literature and one which lends it a unique interest, in addition to its intrinsic merit, is its originality. The Greeks invented all the great types of literature alike in poetry and in prose. Thus epic, lyric, elegy, tragedy, comedy in poetry; history, rhetoric, philosophy in prose—were all alike, as the very names declare, the invention of this extraordinarily gifted people. A people whose literature is based upon foreign models may devote themselves to the cultivation of the different types in any order of succession, or may cultivate the several types in the same age with equal enthusiasm. But the Greeks, having no models, discovered and developed the different forms in logical succession, one being evolved from the other according to the spiritual and social impulses of the time. Moreover, when any one form was developed to its full perfection, they seem to have passed on to another. Hence it is that in Greek literature more than in any other we can speak of a given age as the age, not of this individual writer or of that, but as the age of a particular form of literature.

Greek Poetry to 323 B.C.—Greek literature begins with the Homeric epic, represented for us by the *Iliad* and the *Odyssey*.

There is evidence enough in these poems that they are themselves not primitive in the sense of being a first pioneer effort in the writing of epic. The recurrent epithets and conventional formulae, nay, the very metre in which they are written, imply a long ancestry of poetic practice and experiment. What makes these two epics unique among the epics of all literature is that on the one hand they are sufficiently near the dawn of literature to have yet upon them the dew of the morning, to have all the directness and simplicity and naïveté which we associate with primitive poetry; and on the other hand they belong to a stage of development so far advanced as to have outlived the imperfection of form, and the triviality or vulgarity of thought which, in early poetry, are apt to offend the cultured reader. Moreover, they have developed at once a language and a metre—from what elements and by what stages developed we do not here enquire—which together constitute a vehicle for narrative epic such as no other people have ever possessed. And because of this union of a language uniquely suited to the metre, and a metre uniquely suited to the language, the union has resisted divorce. Down to the latest times, the same language and the same metre continued to be the one medium of Greek epic. The Romans borrowed the metre, but in Roman hands its character is entirely changed, and whatever other merits Roman epic may possess, they are assuredly quite other than the merits of Homeric epic. Attempts to transplant the hexameter (*q.v.*) into English were—for reasons which cannot be here elaborated—foredoomed to failure. And what has become the favourite medium for epic in English, viz., blank verse, suffers in comparison with the Homeric hexameter much in the same way as the Roman hexameter does in comparison with the Greek, a lack of lightness and mobility: defects which both in Roman epic and in English, find their compensation in certain other qualities which are, however, of value only from the point of view of poetry in general, assuredly not from the point of view of epic poetry in particular.

Alongside the Homeric type of *Epos*, i.e., the epic of chivalry, which had for its subject the story of war and adventure in the heroic age, the *κλέα ἀνδρῶν* of *Iliad*, ix. 189, etc., the Greeks early developed quite another type of *Epos*, which had for its business to inculcate the traditional wisdom of the race. As Hesiod, the earliest of the didactic poets, belongs roughly to the Homeric age—in Greek tradition Homer and Hesiod are regularly coupled together and regarded as contemporaries: Herod. ii. 53; Plato, *Rep.* 363 A; 377 D; 599 D; Aristoph., *Ram.* 1,033 seq.—he naturally chose for his didactic poems the Homeric hexameter. Two didactic poems are ascribed to Hesiod—the *Theogony* and the *Works and Days*. True to Greek custom the hexameter remained down to the latest times the recognized medium for didactic poetry. The *Theogony* of Hesiod may be regarded as the forerunner of the philosophical poems bearing the title *Περὶ Φύσεως* (On Nature), of which three were especially notable: (1) that of Xenophanes of Colophon, the founder of the Eleatic school of philosophy, in the second half of the 6th century, whose protest against the unworthy ideas of Homer and Hesiod regarding the gods is well known:

πάντα θεοῖς ἀνέθηκεν Ὀμηρὸς θ' Ἡσίοδος τε
 ὅσσα παρ' ἀνθρώποισιν ὀνείδεα καὶ ψόγος ἐστίν . . .
 ὥς πλεῖστ' ἐφθέγγαντο θεῶν ἀθεμίστια ἔργα
 κλέπτειν μοιχεύειν τέ καὶ ἀλλήλους ἀπατεύειν

("Homer and Hesiod ascribed to the gods everything that men think scandalous and shameful. . . . They recounted very many wrongful acts of the gods—theft, fornication and deception of each other."); (2) Parmenides of Elea, the most distinguished of the Eleatics (c. 504 B.C.); (3) Empedocles of Acragas (born c. 495 B.C.), whose poem was the direct model of the *De Rerum Natura* of Lucretius (Lucret. I. 726 sqq.). On the other hand Hesiod's *Works and Days* was the prototype of a long series of poems of the practical type, including the *Theriaca* and *Alexipharmaca* of Nicander of Colophon, the *Phaenomena* of Aratus, the *Haliectica* of Oppian the Cilician, the *Cynegetica*, attributed to Oppian, but the work of a later poet from Apameia in Syria—all of which are extant, and of the no longer extant *Haliectica* of

Caecalus, Numenius, Pancrates, Poseidonius, as well as of the *Georgics* of Virgil, the *Cynegetica* of Grattius and Nemesianus in Latin.

To the epic age succeeds that of iambus and elegy. Iambus, as a literary form, although it had a long life, from Semonides of Amorgos (c. 625 B.C.) to Callimachus and Herondas in Alexandrine times, never achieved an important independent existence. The reason is sufficiently obvious. The iambus—a short syllable followed by a long (*see* IAMBIC)—as the chief component of ordinary prose speech is not of itself adequate to support an independent type of poetry. It is true that it does so in modern literature, as for example in English. But the mere name "blank verse" by which the iambic metre is usually described practically admits that "blank verse" differs from ordinary prose in either one of two ways. Either it betrays its poetic intention by an exactness of rhythm which is repugnant to prose, i.e., by a rhythm the recurrences of which produce metre, or by the quite adventitious use of rhymed endings, "the invention," as Milton says, "of a barbarous age, to set off wretched matter and lame metre." But in any case the iambus as an independent form never attained first-rate importance in early times, nor does its recrudescence in Alexandrine times in any way suggest that it could ever be of great importance by itself. As we shall immediately see, in conjunction with lyric metres in tragedy and comedy it was able to find a place which could not have been taken either by the epic hexameter or by any other metre.

Elegy, on the other hand, consisting of alternate hexameters and pentameters (*qq.v.*) is the nearest approximation to epic. But there does not seem ever to have been the least danger in Greek of confusing the function of elegy with that of epic. The name *ἔλεγος*, *ἐλεγείον*, *ἐλεγεία*, *ἐλεγεία* is of quite uncertain origin, but everything tends to show that from the first it was essentially of a plaintive character, being regularly accompanied not by the lyre, the instrument of mirth, but by the flute, the instrument of mourning (*ἐλεγχοὶ οἱ πρὸς αὐλὸν ἀδόμενοι θρήνοι*, Didymus *ap. schol. Aristoph.*, *Av.* 217; Pausan. x. 7.5; cf. Aesch., *Ag.* 990, *Eumen.* 332; Soph., *Tr.* 640 sqq.; Eurip., *Hel.* 85, *Iph. Taur.* 146, 1091; Ovid, *Ep.* xv. 7, *Amor.* iii. 9.3; Hor. c. i. 33.2). Who invented the form is not known (Hor. *A.P.* 77).

Quintilian, curiously enough, regards Callimachus as the chief elegiac poet, and Philetas of Cos as the second (x.1.58), and Propertius regards these two poets as his masters (v.1.1). In any case the Greeks, at a very early period, extended the range of elegy far beyond the dirge or lament to poems of war and of traditional wisdom. But they did not, like Ovid, use the elegiac metre as practically a substitute for the epic hexameter. The text of Theognis (of Nisaeon Megara, c. 500 B.C.) in two books, is the longest elegy that has come down to us. It hangs together very loosely and is rather a series of elegies of varying length than a single poem. In the Alexandrine age we have various fragments of the *Aitia* of Callimachus and the whole (with one slight lacuna) of his Hymn entitled the *Bath of Pallas* (*Λουτρά Παλλάδος*) in 142 lines. But the type of elegy which was carried to the highest perfection by the Greeks was what is generally known as the epigram, a highly polished poem in elegiacs, varying in length from a single distich to half-a-dozen or more, and of very various content. This type makes up the great bulk of the collection known as the Greek Anthology (*q.v.*).

Next in order of development and, of course, to some extent coincident in point of time, we have lyric poetry or song, and this of two types—on the one hand the individual or personal song, and on the other the choral lyric. Of the first the remains are exceedingly meagre and, indeed, are chiefly confined to the fragments of Alcaeus and Sappho. Of the high merits of the latter the Greeks seem to have entertained no doubt, and modern critics—whether professed classical scholars or amateurs like Swinburne—have vied with one another in finding words of enthusiastic and extravagant eulogy.

Of choral lyric, on the other hand, we have very extensive remains, both as an independent literary form, and as an element of tragedy and comedy. Of the first our most important representative is Pindar, of whom, apart from considerable fragments,

we possess some 45 odes classed—not always correctly—as epinician odes, or odes in celebration of victors in the games (Olympian, Pythian, Nemean, Isthmian). We have also recovered in recent years (1896) a papyrus containing a certain amount of his junior contemporary Bacchylides, about six poems being practically complete. The manner in which these poets succeed in contriving that a poem which is in the first instance written to celebrate such an ephemeral event as a victory in the games should be of permanent appeal, is a very interesting literary study, which will be more fittingly discussed in connection with Pindar (*q.v.*).

The next important development is the drama, including, of course, both tragedy (with the Satyric drama) and comedy. While in all likelihood these two species of drama were of contemporaneous origin, tragedy was the earlier to attain a high degree of perfection: Aristotle's statement (*Poet.*, c. v., 1449^a36) of the comparatively late date at which comedy was not formally recognized by the State, is confirmed by epigraphic evidence from which it appears the comedy was not officially recognized by the State until 488–487 B.C., while Thespis, the father of Attic tragedy, is said to have produced his first tragedy in 534 B.C.

Tragedy is said by Aristotle to have originated ἀπὸ τῶν ἐξαρχόντων τὸν διθύραμβον ("with the leaders of the dithyramb," *Poet.* 4.1449^a10), and this seems to agree with the facts. The literary development of the dithyramb in honour of Dionysus is associated with the Dorian Corinth, and Greek tragedy on the face of it seems to be a combination of Doric choral song with Ionic dialogue. The great period of Attic tragedy is the 5th century B.C. and is mainly represented for us by the remains of the three great tragedians, Aeschylus (525–456 B.C.), Sophocles (496–406 B.C.) and Euripides (c. 480–406 B.C.) (*qq.v.*). We also possess Euripides' *Cyclops*, the only extant Satyric drama, the recently discovered *Ichneutai* of Sophocles being in a fragmentary form. The usual method of the production of tragedy in the 5th century was in the form of a trilogy of tragedies followed by a δρᾶμα σατυρικόν (Satyric drama). The relation of this last form of drama, in which the spirit is in the vein of comedy, while the chorus is a choir of satyrs, to tragedy is a subject of debate. Aristotle regards the satyric element as original (*Poet.* 4.1449^a19) which seems the more probable view. On the other hand it has been held, both in ancient and modern times, that the satyric element was not original. According to an old view it was superadded to tragedy by way of comic relief (Hor., *A.P.* 220 *sqq.*). Prof. Ridgeway, holding that tragedy originally was non-Dionysiac, but connected with the solemn commemoration of the dead, derives *satyroi* from *Satrai*, a Macedonian tribe, and holds that the introduction of the satyric element was coincident with the introduction of the worship of Dionysus at Athens towards the end of the 7th century B.C.

Comedy originated, according to Aristotle, ἀπὸ τῶν τὰ φαλλικά (ἐξαρχόντων) ἃ ἐτι καὶ νῦν ἐν πολλαῖς τῶν πόλεων διαμένει νομιζόμενα, "with the leaders of the phallic songs which still survive in many cities as an institution" (*Poet.* 4.1449^a 11). This again seems a very probable account, the name *κωμῳδία* being derived, not from *κῶμη*, village, but from *κῶμος*, a company of revellers (Arist., *Poet.* 3.1448^a36 ff). These phallic songs were sung (Aristoph., *Ach.* 261, "And I will follow and sing the phallic song,") by lewdly dressed processionalists, *phallophoroi*, and the intention was by mimetic symbolism to promote fertility (Athen. 621 E. For their dress and procedure cf. Athen. 622 B). Similar customs exist even at the present day, e.g., in Macedonia.

The Alexandrine scholars distinguished Attic comedy into Old (παλαιά) and New (νέα), the further distinction of Middle (μέση) comedy dating only from the time of Hadrian. For us the only poet of the Old Comedy of whom a complete play is extant is Aristophanes (*q.v.*, c. 446–385 B.C.).

We note some features which belong to the earliest stages of comedy. We notice first the frequency with which the chorus, from which the comedy takes its name, represents some species of animal. Similarly we hear of plays by Magnes entitled *Birds*, *Frogs*, *Gall-wasps* (cf. Aristoph. *Eq.* 522 *seq.*). It is impossible to doubt that tragedy in the same way got its name from the fact that the chorus was represented as He-goats (τράγοι), or that

the Satyric drama was also named from its chorus of He-goats (σάτυροι, cf. ὀρίων) Is. 13.21. Puck = Bock (Ger.) = Buck (Eng.). Then we have the *Parabasis* or address to the spectators, also primitive, as is the *Agon* or debate between two opponents. The later plays of Aristophanes show a considerable divergence from the earlier. The three earliest plays—*Acharnians*, *Knights*, *Wasps*—have a fully developed *Parabasis*, while in three of the later plays—*Lysist.*, *Eccl.*, *Plutus*—the *Parabasis* has completely disappeared. Similarly with the place of the chorus in general. Thus in the *Plutus* the office of the chorus is confined to dialogue, and there are no choral songs. The later plays thus exhibit tendencies which are carried still farther in the New Comedy. Menander (*q.v.*, c. 323–293 B.C.), though his date falls in the Alexandrine period, has nothing to do with the Alexandrines: he declined the invitation of Ptolemy I. to go to Alexandria and remained in Athens. The characteristic feature of his comedy seems to have been faithful representation of life (cf. Syrian. in Hermog. 2 p.23 8 Rabe). Although his scanty remains have been greatly augmented in recent years by discovery of papyri, we still have no complete play. The word Χοροῦ appears after *Epitrepontes* 201: otherwise, Chorus, *Agon*, *Parabasis* have completely disappeared.

Greek Prose to 323 B.C.—While prose doubtless preceded poetry, prose as a developed literary form is later than poetry. Hence the history of Greek prose down to 323 B.C. is a much shorter story than that of Greek poetry in the same period. If we take the three great literary types of prose to be history—the novel or romance, when it is developed is merely fictitious history, cf. Bacon, *Advanc. of Learning* ii.: "Poetry . . . in respect of matter is nothing else but feigned history, which may be styled as well in prose as in verse"—oratory, philosophic essay or dialogue—the natural order of development is history (including the fable or apologue, and the speech as subsidiary elements), oratory, philosophic prose.

Three *historians* in this period are represented by complete works. First we have the *History* of Herodotus (*q.v.*, c. 484–425 B.C.). His conception of the function of history is clearly stated in his opening paragraph: 'Ἡροδότου Ἀλικαρνησέος ἱστορίας ἀπὸ δεξιῆς ἦδε, ὡς μήτε τὰ γενόμενα ἐξ ἀνθρώπων τῷ χρόνῳ ἐξίτηλα γένηται, μήτε ἔργα μεγάλα τε καὶ θυνμαστά, τὰ μὲν Ἑλλήσι, τὰ δὲ βαρβάροις ἀποδεχθέντα, ἀκλεᾶ γένηται, τὰ τε ἄλλα καὶ δι' ἣν αἰτίην ἐπολέμησαν ἀλλήλοισι. "This is the history of Herodotus of Halicarnassus, published in order that what has happened may not be forgotten of men by the passing of time, and that the great and admirable actions of the Greeks and the barbarians may not become unappreciated, and in particular the reasons for the war between them." His object is thus simply to prevent the achievements of the past from being obliterated by time; he has no notion that a knowledge of the past should have any bearing either on the conduct of the present or the anticipation of the future. As to his conception of the duty of the historian, we need only note that he travelled widely and used all the sources of information open to him, whether monumental or oral. In matters of dispute, he endeavours to state both sides of the question, but with refreshing candour he warns the reader that he does not affirm the truth of either side (ii. 123, vii. 152). On any view Herodotus must always be regarded as one of the most charming of historians. His air of candour and naïveté (Quintil. x. 1.73) heightened by the archaic suggestion of the dialect (Ionic) in which he writes and the simple structure of his composition (ἁέλις ἐλπομένη), his digressions, his picturesqueness give him an irresistible appeal.

Thucydides of Athens (*q.v.*, c. 460–c. 396 B.C.) wrote a *History of the Peloponnesian War*, now divided into eight books. He tells us (i. 1) that he commenced to write his *History* as soon as the war began, as he foresaw that it was likely to be a greater and more important war than any that had yet taken place, an opinion founded on the fact that both the Athenians and the Lacedaemonians were at the height of their power, while the other Greek States were likely to range themselves on the side of one or other of the protagonists in the conflict. His failure in 424 to save Amphipolis led to his going into exile, a circumstance which

gave him the opportunity to study the war from both sides (v.26). His conception of the function of history differs markedly from that of Herodotus. His idea is that a knowledge of the past is the best guide to the future (i. 22). Two peculiarities of his *History* must be noted. First the annalistic order of treatment. That is to say, instead of treating an episode of the war as a whole, he narrates events *κατὰ θέρος καὶ χειμῶνα*, i.e., after the form of a diary—all the events of a particular summer are grouped together, however unconnected they may be, and these are then followed by the events of the ensuing winter. Another remarkable feature is the use of set speeches composed in a highly elaborate form—showing the exaggerated use of the antithesis which characterized early Greek rhetoric. His own account of the conception of these speeches is given in i. 22: "as to the speeches delivered by the several combatants either when they were about to go to war, or when they were already involved in it, it was difficult both for me in the case of speeches which I heard myself, and for those who reported to me speeches from other quarters, to remember the exact words. I have written what it seemed the various speakers would have said if they spoke to the purpose, while keeping as close as possible to the general sense of what was actually said."

The third of the historians is Xenophon of Athens (q.v., c. 431-c. 355 B.C.). His *Hellenica* in seven books continues the history of Greece from the point reached by Thucydides (411 B.C.) down to the battle of Mantinea in 362 B.C. His *Anabasis* in seven books describes the expedition of Cyrus, the Persian prince, against his elder brother Artaxerxes II. In this expedition 10,000 Greek mercenaries took part. When Cyrus fell in the battle of Cynaxa (401 B.C.) and the Greek leaders were put to death by Tissaphernes, Xenophon caused new leaders to be chosen, including himself. The main part of the *Anabasis* describes the retreat of the Greek mercenaries. Other strictly historical works by Xenophon are his essay upon Agesilaus, king of Sparta; an essay on *Athenian Revenues*; another on *Lacedaemonian Polity*.

The art of *rhetoric* was a development of the 5th century, the pioneer professional teachers of Oratory of whom we chiefly hear being Corax of Syracuse, his pupil Tisias and Gorgias of Leontini (whose style we can infer from the extant fragments). The Alexandrine canon recognized ten Attic orators: (1) Antiphon (q.v., c. 480-411 B.C.) of whom we possess three Tetralogies, each consisting of four speeches, and three speeches in real cases. The interest of these speeches is twofold, first as examples of early forensic oratory, and secondly, all being concerned with cases of murder, as throwing light upon some intimate matters of Athenian social life which would otherwise be obscure; (2) Andocides (q.v., born c. 440), under whose name four speeches are extant; (3) Lysias (q.v.), son of a Syracusan *μέτοικος*, of whom 34 speeches are extant. Simple and unaffected in style, they throw a flood of light on Athenian domestic and social life; (4) Isocrates (q.v., 436-338 B.C., when "that dishonest victory at Chaeronea, fatal to liberty, Kill'd with report that old man eloquent"), of whom we have 21 orations. His interest is chiefly stylistic; he greatly influenced Cicero and through him modern prose style; (5) Isaeus (q.v., fl. c. 360 B.C.), of whom we have 12 speeches (11 and 12 being incomplete). All the speeches, except No. 12, deal with the testamentary disposition of property and are of inestimable value for the knowledge of Attic private law; (6) Demosthenes (q.v., b. 384 B.C.), under whose name we have 69 orations (not all, however, being orations, and not all genuine), the greatest oratory of antiquity (Quintil. x. 1.76). While his fame rests especially on the *Philippics*, *Olynthiacs*, *De Falsa Legatione*, and, above all, the *De Corona*, many of the other speeches are of high merit, while his private forensic speeches are extremely valuable for the information they afford, particularly in regard to the operations of commerce in ancient Greece; (7) Aeschines (q.v., b. 390 B.C.), the great rival of Demosthenes, of whom we have three orations; (8) Lycurgus (q.v., born c. 390 B.C.): one speech extant; (9) Hyperides (q.v., born c. 390 B.C.), of whom we have fragments of six speeches, recovered since 1847 from papyri; (10) Deinarchus (born c. 360 B.C.): three speeches extant.

Philosophic prose is represented by Plato (q.v., b. 427 B.C. on the seventh of the month Thargelion, a day afterwards celebrated annually by the Platonic school—d. 348-7 [his will is quoted Diog. L. iii. 41]), under whose name we have 42 dialogues, besides some dozen letters. Some of the dialogues (in all of which, except the *Laws*, Socrates is an interlocutor) are certainly spurious, others of doubtful authenticity. All we need note here is that in Plato Greek prose attains its supreme perfection, a grace and ease and flexibility, capable of every emotion of which the soul is capable, such as perhaps no other prose in any language has attained. And this, coupled with sublimity and beauty of thought, with power to strengthen those hopes of men which aspire to immortality and seem to promise it, will ensure that such works as the *Apology*, the *Phaedrus*, the *Phaedo*, the *Republic*, will always remain among the most precious heritages of humanity.

Aristotle (q.v., 384-322 B.C.) has left such an immensity of writing that here we can do no more than indicate his chief works under their appropriate headings: 1. Logic: *Topica*, *Analytica*; 2. Natural Science (for which his position as tutor to Alexander no doubt gave him special advantages): *Historia Animalium*, *De Partibus Animalium*; 3. Psychology and Metaphysics: *De Anima*, *Metaphysica*; 4. Ethics: *Nicomachean Ethics*; 5. Politics: *Politica*, *Respublica Atheniensium*; 6. Literature: *Poetics*, *Rhetoric*.

For convenience we may here include Aristotle's successor as head of the Peripatetic school, Theophrastus of Eresos (c. 372-287 B.C.), of whose writings we possess only: 1. *Historia Plantarum* (Περὶ φυτῶν ἱστορίας). 2. *De causis plantarum* (Περὶ φυτῶν αἰτιῶν). 3. *Characters* (χαρακτῆρες), and a few short pieces such as *De Signis* (Περὶ σημείων), which was apparently one of the sources used by Aratus for that part of the *Phaenomena* (733-1154) which is called *Διοσημίαι*, and some smaller fragments.

The Alexandrine Age, 323 B.C.-A.D. 100.—1. Before reviewing the Alexandrine poets individually, it is worth while to note certain characteristics of the Alexandrine poetry in general. In the first place it is no longer an original poetry like that of the Classical period, but imitative. One symptom of this is that quite different kinds of poetry are cultivated by the same poet. Next it is a learned poetry for the most part, and makes its appeal in the first place to a learned audience—being full of learned allusions, strange or archaic or dialectic words (γλῶσσαι) which had little meaning for the ordinary man. Again, as in all learned poetry, the mere knowledge of the work of an earlier poet impels the imitator in the search for novelty to sacrifice simplicity. What is meant can be well seen by comparing Homer's description of the abode of the gods in *Odyssey* vi. 42 sqq. with the successive imitations by Lucretius, Tennyson, Swinburne and again Tennyson. And the need for extreme elaboration tends to the cult of the short and highly polished poem rather than of the longer poem in which such uniformly high polish would make an excessive demand alike on the poet and on his reader. Again we note that the passion of love becomes now not a subsidiary, but a leading motive. Finally we notice a tendency—not perhaps unconnected with the growth of large cities—to take for theme the happiness of the simple peasant's life.

Callimachus (born c. 310 B.C.) is represented by six Hymns (five in hexameters, one in elegiacs), and by a large number of fragments in a variety of metres. Recent discoveries of papyri have added considerably to our knowledge of his work (especially the *Αἴτια* and *Ἰαμβοί*). He is the champion of the short poem (Athen. 72 A). On the other hand his contemporary and rival, Apollonius Rhodius, attempted in his *Argonautica* in four books (5,835 lines) to revive the long epic (cf. Callim. *Hymn* ii. 106, with Apollon. Rh. iii. 932 seq.). The didactic epic is revived by Aratus of Soli in Cilicia (born c. 315 B.C.) in his *Phaenomena* (1,154 lines), an astronomical poem, sometimes called *Φαινόμενα καὶ Διοσημίαι* because it falls into two well marked divisions—sometimes considered to be distinct poems—1-732 describing the relative position of the stars in the heavens and their risings and settings, 733-1154 dealing with weather signs in general. The poem, which was greatly praised in later times (Ovid, *Amor.* i.15.6) and was translated by Cicero, contains two passages of unusual beauty, the *Prooemium*, from which St. Paul quotes

(Acts xvii. 28: "As certain also of your own poets have said, 'For we are also his offspring'") and the lines (96-136) which tell how Justice forsook the earth. Nicander (born c. 200 B.C.) continued the didactic epic in a series of poems of which two are extant: *Theriaca* (958 lines), on the bite of venomous beasts, and *Alexipharmaca* (630 lines), on antidotes. Neither of them has any poetic value.

We hear of a *Pleiad* of eminent tragedians of the time of Ptolemy Philadelphos, but we have no extant comedy or tragedy. Lycophron, one of the *Pleiad*, has left us, besides a few short fragments of tragedy, a poem of notorious difficulty called *Alexandra*, i.e., Cassandra. Elegy is largely cultivated, the most famous elegist being Philittas (Philetas) of Cos (c. 300 B.C.), whose name is also associated with that of Callimachus by Propertius (iv.1.1).

The one important new poetic development of the period is the bucolic idyll associated with the names of Theocritus (born c. 305 B.C. in Syracuse, cf. *A.P.* ix. 434, Athen. 284 A) and the later Bion and Moschus (probably 2nd century B.C.). This type of poetry, a short poem in hexameters dealing with country life, and especially with herdsmen, goatherds and shepherds, became the model for the *Bucolics* of Virgil, and through him of all later pastoral poetry. The beautiful lament for Bion (= Mosch. *Id.*), the authenticity of which some now deny, was the model for Virg. *Bucol.* X., Milton's "Lycidas," and Shelley's "Adonais." The curious type of poetry called a mime, which has apparently some affinity with the idyll, is now represented by the eight mimes of Herondas (discovered in Egypt, 1890). The papyrus ms. obtained from the Fayum is in the possession of the British Museum.

2. The *prose literature* of the Alexandrine age is, for the most part, a learned literature. All branches of learning were cultivated with assiduity. The work of the Alexandrines in the department of literary criticism is discussed in a later part of this article. Their work in science—particularly mathematics and astronomy—hardly concerns us here. But a word must be said of three writers of this time who are of more general interest. Polybius (q.v., c. 201-120 B.C.) of Megalopolis in Arcadia, composed his *Histories* (Ἱστορίαι) in 40 books, of which only the first five are extant in their entirety, but we know the plan of the whole work. Polybius has none of the graces of style, his virtues being those of accuracy in detail and sound judgment. Strabo (q.v., c. 63 B.C.-A.D. 19) of Amaseia in Pontus, wrote a historical work (Ἱστορίαι) in 43 books, which dealt cursorily with the period before Polybius, and in detail with the period after Polybius (Suid. s. Πολύβιος): of this only fragments are preserved (*Frag. Histor. Gr.* iii. 490 sqq.). But his *Geography* (Γεωγραφικά), is preserved almost entire. Quite apart from its value as a contribution to the study of geography, his work is of extraordinary interest to the general student from the multitude of incidental information which it gives with regard to the various peoples mentioned in the course of the treatise. Plutarch (q.v., c. A.D. 46-120) of Chaeroneia in Boeotia, was a many sided polymath, most of whose works are fortunately extant. They fall into two groups, the *Parallel Lives* (probably mostly the work of his later life) and the series of popular essays called collectively *Moralia* (Ἠθικά). The *Parallel Lives* (Βίοι Παράλληλοι) consist of a series of biographies (46 extant) of eminent historical characters, a distinguished Greek being coupled with a distinguished Roman, to whom he seemed, in point of career, to bear some resemblance, each couple of biographies being followed by a *Comparison* (Σύγκρισις), in which the two are compared. The order of the biographies as given in the mss. is not that of our ordinary editions, which is based upon the Aldine edition and is without ms. authority, but partly follows chronological order. This arrangement, however, is not Plutarch's: thus, e.g., we know from Plutarch himself (*Theas.* 1) that the *Lives* of Lycurgus and Numa were written before those of Theseus and Romulus. The *Moralia* is an immense collection (7 vols. in Teubner ed.) of essays on the widest variety of topics, ethical (these in the majority—hence the general title), historical, scientific. Though not profound, Plutarch is generally interesting, and the incidental allusions are often of the greatest value.

ROMAN LITERATURE

The story of Roman literature is a comparatively short one. Its whole lifetime is not equal to that single epoch of Greek literature which we call the Alexandrine age. Again, while the literature of Greece exhibits a completely independent development, Roman literature is at every point based upon Greek models. A consequence of this is that, while Greek literature shows a logical development, that of Rome develops more or less fortuitously. While, then, Greek literature is best presented in the order of evolution of the several literary types, there is no such reason for adopting the same method in summarizing the content of Roman literature, and the most convenient method of presentation is the chronological.

Roman literature may be said to begin about the middle of the 3rd century B.C., and it is conveniently divided into three periods: (1) the Republican age, 250-27 B.C.; (2) the Augustan age, 27 B.C.-A.D. 14; (3) the Imperial age, A.D. 14-524.

The Republican Age.—An account of the origins of Roman literature and of its representatives will be found under **Latin Literature**: here, where our object is merely to present a conspectus of the extant literature, the earliest period from which nothing but detached fragments survive, may be dismissed with a reference to the articles on Livius Andronicus (c. 284-204 B.C.), C. Naevius from Campania (d. Utica 201 B.C.), Q. Ennius (239-169 B.C.), M. Pacuvius (b. 220 B.C.) and L. Accius (b. 170 B.C.).

Far more important from our point of view are two poets who wrote comedies only. T. Maccius Plautus (q.v.) of Sarsina, in Umbria (c. 251-184 B.C.), is represented by 21 extant comedies—the so-called *fabulae Varronianae* (Aul. Gell. iii. 3. 3). They are all translated more or less closely from the Greek (cf. *Trin. prol.* 18 *Huic Graece nomen est Thensauro fabulae: Philemo scripsit: Plautius vortit barbare, Nomen Trinummum fecit, and Asin. prol.* 10).

P. Terentius Afer (q.v., c. 190-159 B.C.) of Carthage became the slave of Terentius Lucanus, whose name he took on manumission. Six of his comedies are extant. His chief model was Menander: cf. Caesar's lines *ap. Sueton. Vit. Ter.* "Tu quoque tu in summis, O dimidiate Menander / Poneris et merito, puri sermonis amator: / Lemibus atque utinam scriptis adiuncta foret vis / Comica, ut aequato virtus polleret honore / Cum Graecis neque in hac despectus parte iaceres: / Unum hoc maceror et doleo tibi desse, Terenti." ("You too, even you, half-Menander, are ranked among the highest and rightly, lover of pure Latin; but I wish your smooth verse had comic power, that its virtue might be equally honoured with the Greek and you were not despised in this respect. Terence, I am hurt and pained to find you lack this one thing.") The merit and demerit of Terence, as here stated by Caesar, are precisely what strikes the modern student—the purity of his Latin and his lack of force. In the economy of his comedies, we note an innovation in that the prologue no longer has the function of introducing the play, but serves—much like the Parabasis in Aristophanes—as a vehicle of criticism (cf., e.g., *Adelph. prol.* 15 seq.; *Heaut. prol.* 22).

The earliest work in Latin prose which is extant entire is the *De Agri Cultura* of M. Porcius Cato (q.v., 234-149 B.C.), a mere compendium of precepts on agriculture. His *Res Rusticae* (three books) is also the only complete work extant of M. Terentius Varro (q.v., 116-27 B.C.), the most learned Roman of his time, who in his long life produced an extraordinary variety of works. His agricultural treatise is an immense advance on that of Cato in point of style. Of Varro's work *De Lingua Latina* in 25 books, only 5-10 are extant.

In the hands of Varro's younger contemporary, M. Tullius Cicero (q.v., 106-43 B.C.), Latin prose style attains its highest perfection. Cicero's literary activity is amazing. Apart from his speeches (of which 58 are extant), we have several treatises on rhetoric, a great number of works on philosophy—largely written in the last two or three years of his life and particularly after the death of his daughter Tullia, and finally his correspondence: letters (1) *Ad Familiares* (16 books, 62-43 B.C.), (2) *Ad Quintum Fratrem* (3 books, 60-54 B.C.), (3) *Ad Atticum* (16 books, 68-44 B.C.), (4) *Ad M. Brutum* (2 books, 43 B.C.). The letters, written

as they are in a completely intimate and informal manner, constitute an extraordinarily important commentary on the events of his time and, revised in relation to those events, form a very interesting psychological study. C. Julius Caesar (*q.v.*, 102-44 B.C.) wrote a treatise, *De Analogia* (two books), which one would have liked to see, and a tragedy *Oedipus*, which one would have liked to see still more. We possess, however, his *Commentarii de bello Gallico*, seven books, covering the years 58-52 B.C., and *Commentarii de bello civili*, three books, covering the years 49-48 B.C. The *Bellum Alexandrinum* is probably by A. Hirtius, who also added an eighth book to the *Bellum Gallicum*. The authors of the *B. Hispaniense* and *B. Africanum* are unknown. Q. Sallustius Crispus (86-34 B.C.) of Amiternum, wrote the *De Catilinae coniuratione* and the *Bellum Iugurthinum*, both extant, and *Historiae*, covering the years 78-67 B.C., of which we have some fragments.

Poetry in this period is represented by two names of the first rank. T. Lucretius Carus (*q.v.*, c. 99-c. 55 B.C.) expounds the philosophy of Epicurus in his *De Rerum Natura* (six books), the title being a translation of *Περὶ Φύσεως*, the title of poems by Xenophanes, Parmenides, Empedocles. He had a high reputation in antiquity. Virgil, who was greatly influenced by him and refers to him (without naming him) in a famous passage of the *Georgics* ii. 490, *Felix qui potuit rerum cognoscere causas Atque metus omnes et inexorabile fatum Subiecit pedibus strepitumque Acherontis avari*, is preferred to him by Quintilian (X. 1.86 *seq.*), on grounds which merely concern the student of oratory, and this preference has been supported by the general judgment, but not a few good judges would reverse the verdict. The strictly philosophical passages no longer appeal, but in the more popular passages, such as the Proemium (i. 1-43), the eulogy of Epicurus (iii. 1-30), on the folly of fearing death (iii. 892-910), his passionate earnestness (*docti furor arduus Lucretii*, Stat. *Silv.* ii. 7.76), coupled with genuine poetic imagination and a real gift for poetic expression, affects the modern reader perhaps more than anything in Virgil. C. Valerius Catullus (*q.v.*, b. at Verona [Catull. lxvii. 34, Mart. xiv. 195, Ov., *Am.* iii. 15.7] 84-d. c. 54 B.C.), the greatest of Roman lyric poets, is represented by 116 poems in a variety of metres, hendecasyllables, iambic, trimeters (including scazons), sapphics, priapean, phalaecean, asclepiadean, hexameters, elegiacs, iambic tetrameter catalectic, galliambic (lxiii). Most of his poetry shows strong marks of Greek influence, and several poems are translations from the Greek: e.g., li. (from Sappho), lxvi. (from the lost *Hair of Berenice* of Callimachus). His hexameters and elegiacs—though sometimes extremely effective, as in his lines at his brother's grave (ci.)—show much less grace and ease than his hendecasyllabic and priapean poems. Apart from technique he has the two chief gifts of the lyric poet—depth of feeling ("Tenderest of Roman poets nineteen hundred years ago"—Tennyson) and simplicity.

The Augustan Age, 27 B.C.-A.D. 14.—P. Vergilius Maro (70-19 B.C., see VIRGIL), generally regarded as the greatest of Roman poets, is represented by (1) *Bucolica* (*Eclogae*) ten poems in which Theocritus is imitated or even translated. Of these, only ii, iii, v, vii, and viii. are strictly pastoral, the pastoral setting in others being merely a framework, while in iv. (the so-called Messianic Eclogue) there is nothing of the pastoral at all; (2) *Georgica*, in four books (i. Agriculture, ii. Tree culture, iii. Cattle-rearing, iv. Bee-keeping). The *Georgics* contain some of Virgil's best poetry, e.g., the praise of Italy, ii. 136-176; the eulogy of country life, ii. 458-540; the story of Orpheus and Eurydice, iv. 453-527; (3) *Aeneis*, in 12 books, the great national epic of Rome which, after ten years' work, was still unfinished (witness the "pathetic half-lines," the occasionally uncompleted hexameters) at his death, and was published by L. Varius against the expressed wishes of the poet. Virgil was a slow and careful writer (Quintil. x. 3.8, cf. Donat., *Vita Verg.* ix., Aul. Gell. xvii. 10.2). This very care and elaboration probably rather militates against the essentially epic virtues, and it is not so much as a whole that the poem appeals, at any rate to the modern world, as in certain supreme passages in which the poet rises above his immediate theme and which are really in the nature of digressions. Q. Horatius Flaccus (65-8 B.C., see HORACE), born at Venusia, was the son of a freed-

man (cf. Hor. *Sat.* i. 6.6; 45, 86). After the battle of Philippi (44 B.C.) he returned to Rome where presently he became a member of the circle of Maecenas. His extant work is of two quite different classes—lyrical (*Odes*, *Epodes*, *Carmen Saeculare*) and poems in hexameters (*Satires*, *Epistles*, *De Arte Poetica*). The *Satires* (*saturae* or *Sermones*) in two books, written between 41 and 30 B.C., deal lightly with the foibles and follies of social life, and the *Epistles*, 20-13 B.C., in two books, are very much in the same style as the *Satires*, with a greater preponderance of literary themes, which is emphasized in the epistle which bears a separate title: *On the Art of Poetry*. It is upon his lyrical poems that the fame of Horace as a poet really rests (Quintil. x. 1.96), and his success is due, not to any rare and high gift of poetic inspiration, but to his capacity for expressing with unsurpassed felicity, the common thoughts which touch most nearly the common heart of humanity. Albius Tibullus (*q.v.* d. 19 B.C. while still young) belonged to the circle of M. Valerius Messalla Corvinus, and was on friendly terms with Horace, who addressed to him *Carm.* i. 33 and *Ep.* i. 4, and Ovid (cf. Ov. *Tr.* iv. 10.51, and the beautiful elegy on Tibullus, Ov. *Amor* iii. 9). We possess four books of elegies under his name, but Bk. iii. is by "Lygdamus," a pseudonym for some undetermined poet; iv. 1 (panegyric on Messalla) is by some unknown author, while iv. 7-12 are by Sulpicia, a poetess of the time of Tibullus. To call him "polished and elegant" as Quintilian does (x. 1.93) hardly does justice to his tender grace.

Sextus Aurelius Propertius (*q.v.*, born c. 49 B.C. in Umbria, probably at Asisium [Assisi], where the name Propertius occurs in inscriptions) is represented by four books of elegies. Propertius has an irregular strength which is in marked contrast to the equable polish of Tibullus, and in the matter of form his pentameters have an elasticity and freedom which make the elegiac distich in his hands almost a new metre. Bk. iv. 11—the concluding elegy in our collection—is an excellent example of his mature style. P. Ovidius Naso (b. Sulmo 43 B.C.—died c. A.D. 18, see OVID) has left us a great variety of work. His undoubted poetic qualities are rather obscured by the amazing polish and facility of his versification. There remain but two poets of the Augustan age who need be mentioned here, both writers of didactic epic, Gratius, a contemporary of Ovid (Ov. *Ep. ex Pont.* iv. 16.34), wrote the *Cynegetica*, a treatise on hunting after the Greek model, of which 541 lines are extant. Manilius, of whom nothing is known except what can be inferred from his poem—he must have written after A.D. 9, because in i. 898 he refers to the defeat in that year of Varus in the Teutoburg forest—wrote *Astronomica* (in five books), which is extant.

The prose writers of the Augustan age include only one name of first importance. T. Livius (59 B.C.-A.D. 17, see LIVY), was born at Patavium (Padua, cf. Mart. i. 61.3). In Rome he enjoyed the friendship of Augustus in spite of his admiration of Pompey (Tac. *Ann.* iv. 34). We hear of philosophical works and semi-philosophical dialogues written by him (Senec. *Ep.* 100.9), but his fame rests on his history of Rome (*Historiae ab urbe condita*) down to his own day (it was actually carried as far as 9 B.C.). The work was in 142 books, of which there are extant 35, viz., i-x. (down to 293 B.C.), xxi-xlv. (218-167 B.C.). The lost books are represented by *Periochae* (summaries of contents) composed c. 4th century A.D., which we possess for all except 136 and 137. An Oxyrhynchus papyrus preserves some excerpts from Bks. 37-40; 48-55. Livy, deficient as he was in technical equipment, is not exactly a scientific historian, but he is at least an honest one. In style he is nearer Cicero (cf. Quintil. x. 1.39) than Sallust. His language (despite Asinius Pollio's reproach of *Patavinitas*, Quintil. i. 5.56; viii. 1.3, the reference of which is obscure), with its somewhat poetical colouring, is splendidly adapted to his task (Quintil. i. 1.101). Other minor prose writers are Pompeius Trogus, L. Annaeus Seneca of Corduba (Cordova), and Vitruvius Pollio (*q.v.*).

The Imperial Age.—Under Tiberius in A.D. 30, C. Velleius Paterculus wrote for M. Vicinius (consul in that year) his *Historia Romana*, a sketch of Roman history in two (extant) books. A contemporary writer of first importance, L. Annaeus Seneca (A.D. 3-65), son of the elder Seneca, has left us nine tragedies imitated from the Greek, and numerous prose philosophical

writings. M. Annaeus Lucanus (A.D. 39–65), nephew of the foregoing, is represented by an epic in ten books *De Bello Civili*, on the civil war between Pompey and Caesar. More rhetorical than poetical, Lucan has some memorable lines. Aulus Persius Flaccus (A.D. 34–62), is the author of six satires, mainly on the literary life of his time and on quasi-philosophical subjects. T. Calpurnius Siculus, in the reign of Nero, has left us seven eclogues full of adulation of Nero; the anonymous poem *De Laude Pisonis* is also now attributed to him. L. Iunius Moderatus Columella, contemporary with Seneca, is the author of 12 books *De Re Rustica* in prose except the tenth book which is in hexameters. Next we have a group of four poets: P. Papinius Statius (b. between A.D. 40 and 45, died c. 98) author of two epics—*Thebais* and *Achilleis*—and a collection of poems in various metres with the general title *Silvae*. Valerius Flaccus in the time of Vespasian, to whom his poem is dedicated, wrote the *Argonautica* in eight books. The matter is mainly taken from the *Argonautica* of Apollonius Rhodius and the style is a rhetorical imitation of Virgil. T. Catius Silius Italicus (d. 101) in the reigns of Nero, Vitellius and Vespasian, wrote an epic *Punica* (17 books). His poem, the matter of which is mainly taken from Livy, is highly rhetorical and has little poetical merit. A much more brilliant poet is M. Valerius Martialis (born c. A.D. 40, d. shortly after 100), represented by 14 books of epigrams, some being of remarkable beauty.

C. Plinius Secundus (c. A.D. 23–79) in 77 presented Titus with his *Naturalis Historia* (in 36 books). Quite devoid of style and of no independent authority, the work is of considerable importance as preserving information from authorities now lost. M. Fabius Quintilianus (c. A.D. 35–95) is the author of the *Institutio Oratoria* in 12 books, book x. containing a sort of comparative sketch of Greek and Roman literary history, which includes very happy critiques of the leading Greek and Roman writers. The greatest prose writer of the Imperial age is C. Cornelius Tacitus (c. A.D. 54–c. 118); we have his *Dialogus de Oratoribus*, *Agricola* (A.D. 98) *Germania* (about the same date), *Historiae* (A.D. 69–96), *Annals* (probably written after A.D. 116). C. Plinius Caecilius Secundus (61–c. 114), nephew of the elder Pliny, is represented by nine books of letters, and in addition by the historically very important *Panegyricus* on Trajan and the correspondence with Trajan (including the extraordinarily important letters 96 and 97, dealing with the trial of the early Christians). C. Suetonius Tranquillus, who, under Hadrian, held the office of imperial secretary (*ab epistulis*), wrote the lives of the emperors (*De Vita Caesarum*) from Caesar to Domitian. We have also his treatise *De Grammaticis et de Rhetoribus*, originally part of a larger work, *De Viris Illustribus*, of which the extant *Vitae* of Terence, Horace, Lucan, Passienus Crispus, and the elder Pliny are fragments. D. Iunius Iuvenalis (b. Aquinum, probably A.D. 67) has left 15 satires written under Trajan and Hadrian. Juvenal is a master of vivid phrase: e.g., his account of street dangers in *Sat.* iii. 264 sqq. So his single lines are memorable: “*facit indignatio versum*” (i. 79), “*mens sana in corpore sano*” (x. 356), “*maxima debetur puero reverentia*” (xiv. 47). We must dismiss the remaining authors summarily—with again a reference to their separate biographical articles and the article LATIN LITERATURE: M. Cornelius Fronto (2nd century A.D.); Aulus Gellius (born c. 130); L. Apuleius (b. at Madaura, in Africa, A.D. 114); the *Pervigilium Veneris*, by an author unknown; Ammianus Marcellinus (born c. 332); Decimus Magnus Ausonius (born at Bordeaux c. 300); Claudius Claudianus (born at Alexandria, died 404); Aurelius Prudentius Clemens, the first great Christian poet; C. Lollius Apollinaris Sidonius (c. 430–480), and lastly, Boethius (born c. 480, executed 524).

HISTORY OF SCHOLARSHIP

Pre-Alexandrine.—The history of classical scholarship goes back to a date so early that it is hardly possible to fix a superior limit. As soon as a philosopher began to criticize a literary work (e.g., Xenophanes on Homer and Hesiod), so soon scholarship in the widest sense may be said to have begun. Philosophic speculation soon raised the question of the relation of the name to the thing named, or, in other words, directed attention to the true or inner meaning of words, the *ἐτυμολογία*, as opposed to the

conventional meaning, and thus founded the science of etymology. Directly connected with this was the question of the right use of language, *ὀρθόεπεια*, with which the name of Protagoras (born c. 485 B.C.) was especially connected (Plato, *Phaedr.* 267 C.). This again naturally led to a consideration of the function of words in a sentence and thus to the evolution of a grammatical terminology. Plato already distinguished *ὄνομα* and *ῥήμα*, not so much as noun and verb, but as subject and predicate (cf. Plato *Sophist.* 261; “There are two sorts of intimation of being given by the voice. . . . That which indicates action we call a verb . . . and the other, which is an articulate mark set on those who do the actions, we call a noun” cf. *Cratyl.* 425 A., Aristoph. *Nub.* 681 sqq.) Aristotle distinguished *ὄνομα*, *ῥήμα*, *ἄρθρον* (*Poet.* xxi. 7), *σύνδεσμος* (*Rhet.* iii., 5.2, etc.)—noun, verb, article, conjunction.

Alexandrine Period, 300–1 B.C.—Alexandria (for description cf. Strabo 793 sqq.) was founded by Alexander the Great in 331 B.C. After his death it became the capital of Egypt and the seat of the Ptolemaic dynasty. Under Ptolemy Soter (323–285 B.C.) and Ptolemy Philadelphus (285–247 B.C.) the two libraries and the museum of Alexandria became the greatest centre of literature and learning in the world.

The first librarian was Zenodotus of Ephesus (c. 325–260 B.C.). As librarian he classified the epic and lyric poets, the tragedians being classified by Alexander Aetolus, the comedians by Lycophron. As a scholar he made a critical recension of the *Iliad* and the *Odyssey*, founded on numerous mss., and compiled a Homeric glossary (*Ὅμηρικαὶ Γλῶσσαι*). He seems also to have dealt with the text of Hesiod, Anacreon and Pindar. As a critical scholar he seems to have erred on the side of too great subjectivity.

The poet Callimachus, who did much in the way of making catalogues (*πινάκες*), is often said to have succeeded Zenodotus as librarian, but there is no evidence for the statement (cf. *Callimachus*, Loeb ed. p. 6 sqq.). The next librarian of whom we hear is Eratosthenes of Cyrene (born c. 275 B.C.), who became librarian c. 235. A man of many-sided learning (hence called by his admirers *pentathlos*, while his detractors called him *Beta*, implying that he was second-best in all departments, but first in none), he wrote on geography, mathematics, astronomy, chronology. We are here concerned only with his work in classical scholarship, in which his chief production was a treatise on Old Attic Comedy (*περὶ τῆς ἀρχαίας κωμῳδίας*). His successor in the librarianship was Aristophanes of Byzantium, who became librarian in 195 B.C. He edited Homer, Pindar, Euripides, Aristophanes. He also elaborated a system of critical signs (obelus, sigma, antisigma) and accentuation, divided the strophes of the lyric poets into *κῶλα* (“limbs”) and made an epitome of Aristotle’s *Natural History* (ed. Lambros 1885). His successor, Aristarchus of Samothrace (c. 217–145 B.C.), enjoyed still greater fame and became for later antiquity the type of the philologist (Cic. *Ad. Att.* i. 14.3). He published two editions of Homer, in which he followed the admirable principle, “Ὅμηρον ἐξ Ὁμήρου σαφηνίζειν” (explaining Homer by Homer), edited Hesiod, and concerned himself also with the text of the lyric poets, the tragedians, Herodotus, and Aristophanes, writing both continuous commentaries (*ὑπομνήματα*) and treatises on special questions (*συγγράμματα*). Aristarchus was the first to recognize the eight parts of speech (Quintil. i. 4.20) *ὄνομα* (noun), *ῥήμα* (verb), *ἀντωνυμία* (pronoun), *ἐπίρρημα* (adverb), *μετοχή* (participle), *ἄρθρον* (article), *σύνδεσμος* (conjunction), *πρόθεσις* (preposition).

His pupil, Dionysius Thrax (c. 170–90 B.C.), wrote a Greek grammar, *Τέχνη Γραμματική*, which retained its vogue down to the Renaissance and has been the ultimate model of all modern grammars (ed. Uhlig, Leipzig, 1884). Didymus, on account of his industry surnamed *χαλέντερος* (copper-guts), wrote on Homer, Hesiod, Pindar, Bacchylides, the comedians, the Attic orators, and Thucydides.

Post-Alexandrine Period, 1 B.C.–1350.—Dionysius of Halicarnassus (who lived at Rome from 30 B.C. onwards) wrote a number of valuable works on literary criticism: *Letters to Ammaeus I. and II.*, *De Compositione Verborum*, *De Oratoribus Antiquis*, *Letter to Pompeius*, etc. A very valuable treatise *On the*

Sublime (Περὶ ὑψους) is extant, probably of the 1st century A.D. Apollonius Dyscolus (c. 130) wrote a valuable treatise on syntax in four (extant) books. The most valuable feature of the scholarship of this period is a series of works on lexicography and kindred subjects by Moeris, Phrynichus, Harpocration, Pollux, Hesychius, Stephanus, Suidas, Photius, and the 12th century *Etymologicum Magnum*. Mention should be made of the *Deipnosophistae* of Athenaeus (2nd century) which preserves much curious information and is the source of most of the extant fragments of the Greek comic poets. Libanius (c. 314-393) is the author of a Life of Demosthenes and of Arguments to his speeches. With him we must close the tale of classical scholarship for nearly 1,000 years.

The Revival of Learning or the Italian Period 1350-1527.

—A general account of the Renaissance is beyond the scope of this article and we can merely mention some of the leading names. Francesco Petrarca (1304-74) and Giovanni Boccaccio (1313-75) have an interest only as pioneers, being interested in Greek, but not themselves expert Greek scholars. Manuel Chrysoloras (1350-1415), a Greek immigrant, taught Greek in Florence (1396-1400). It was at the instigation of another Greek, Gemistus Plethon (1355-1452), that Cosmo de' Medici founded an academy for the study of Plato. His pupil, Joannes Bessarion (1403-72), a native of Trebizond, came to Italy in 1439 with the Greek emperor in an endeavour to unite the Greek and Roman churches. Thereafter he joined the Roman Church, becoming presently bishop of Frascati. He died at Ravenna in 1472, bequeathing his collection of mss. to Venice (St. Mark's Library). Theodorus Gaza (c. 1400-c. 1478), of Thessalonica, taught Greek for a time at Ferrara, afterwards in Rome and Naples. His Greek grammar was printed by Aldus Manutius at Venice in 1495, and he was also the author of translations of Aristotle, Aelian, Theophrastus *De Plantis*, and of Dionysius, *De Comp. Verborum*. Demetrius Chalcondylas (1428-1510) edited Homer (*ed. princeps*, 1488), Isocrates, Suidas. Laurentius Valla (1407-57) translated Homer, Herodotus, Thucydides. But the greatest philologist of the Renaissance was Petrus Victorius (1499-1584), who edited Sophocles, Isaeus, Aristotle's *Rhetoric*, *Poetics*, *Ethics*, *Politics*, Cicero, Terence, Sallust, Varro's *De Re Rustica*. Lastly, among famous collectors of mss. may be mentioned Poggio Bracciolini (1380-1459), who discovered a great number of Latin mss., and Giovanni Aurispa (c. 1370-1459), who, in 1423, brought to Venice 238 mss. including *Venetus A.* of the *Iliad* and the *Codex Laurentianus* (10th century, now in Florence) of Aeschylus, Sophocles and Apollonius Rhodius.

The Greek grammar (Ἑρωτήματα) of Constantius Lascaris printed at Milan by Paravisinus in 1476, was the first book to be printed wholly in Greek.

Later Periods.—*The French Period*, 1530-1700, is characterized by an interest more in the content than the form of the classical authors. Leading names are Budaeus (1457-1540), Robert (1503-69) and Henri Etienne (1528-98), Turnebus (1512-65), Casaubon (1559-1614), Joseph Justus Scaliger (1540-1609), Du Cange (1610-88) (*qq.v.*).

The English and Dutch Period (18th century) is a period of comprehensive scholarship—of historical and literary as well as verbal criticism. The leading English scholars are Richard Bentley (1662-1742) and Richard Porson (1759-1808), while in the Netherlands the chief names are Ezechiel Spanheim (1629-1710), the two Burmans (the elder 1668-1741, the younger 1714-78), Hemsterhuis (1685-1766), Valckenaer (1715-85), Wyttenbach (1746-1820) (*qq.v.*).

The German Period is inaugurated by F. A. Wolf (1759-1824), whose *Prolegomena* to Homer was published in 1795. In this period we have two distinctive types of scholarship—the historical and antiquarian on the one hand and the critical and grammatical on the other. Leading representatives of the former are B. G. Niebuhr (1776-1831), August Boeckh (1785-1867), K. O. Müller (1797-1840), Otto Jahn (1813-69), Theodor Mommsen (1817-1903), and of the latter G. Hermann (1772-1848), Lobeck (1781-1860), Immanuel Bekker (1785-1871) (*qq.v.*).

Present Day.—It would perhaps be invidious to mention the names of distinguished scholars either recently gone from us or still living, but a few words may be said of certain features which characterize classical scholarship of the present day.

The most notable development of modern times has been undoubtedly the increased interest in archaeology, in the widest sense, which has been witnessed in the last 100 years, and more particularly in the last half century. As this is written, it is almost exactly a century since the foundation of the Archaeological Institute in Rome (1829). The French schools in Athens and Rome were founded respectively in 1846 and 1873, those of the United States in 1882 and 1895, the British schools in 1883 and 1901. Everywhere, ancient sites have been and are being excavated—Troy, Delphi, Mycenae, Tiryns, Sparta, Olympia, Epidaurus, Dodona, Delos, Crete have yielded results beyond all expectation—while the recovery of papyri from Egypt has not merely restored to us a considerable body of ancient Greek literature, such as Aristotle's *Constitution of Athens* (1891), Herondas (1891), Bacchylides (1897)—to mention only some examples—but has thrown a valuable light on the true nature of New Testament Greek.

The study of one department of archaeology, namely that of anthropology, and in particular of primitive ritual and religion, has strongly influenced the study of classics. There was a time when the attention of scholars was perhaps too exclusively devoted to the literary aspects of the classical writers—to textual criticism and the study of form. As a natural consequence the labours of successive generations were confined to the great literary masterpieces of antiquity, while comparatively little study was given to writers of inferior genius who, nevertheless, preserve for us antiquarian and anthropological information of the first importance. Moreover, much that even in the best authors was either overlooked or misunderstood, has taken a new meaning in the light of the comparative study of the beliefs and institutions of primitive man. It is hardly too much to say that archaeological and anthropological discovery and speculation have been a fruitful and vivifying development of classical studies in recent years.

But the interest in "pure scholarship" which has long been a distinctive feature of the study of classics in this country is still fully maintained. The practice of composition in Greek and Latin, which for long occupied a leading place in our school and university education, appears to have somewhat retrograded, and the art of verse composition in particular seems to be falling into some neglect. On the other hand, there has been in the last 50 years an increasing interest in the art of translation from the classics, and an increasing demand for translations which should be at once accurate in point of scholarship and acceptable from the point of view of literary form. This has been the aim successfully pursued by many scholars writing independently, while it is the professed purpose of such a series as the Loeb in the United States and the Budé series in France.

Although the classics no longer enjoy their old monopoly in education, the study of the Greek and Latin writers seems to flourish as vigorously as it has done at any time, and at the present moment, so far as the evidence goes, the prospects of classical scholarship as an indispensable force in education appear to be singularly bright. See also GREEK LITERATURE; LATIN LITERATURE. (A. W. MA.)

CLASSIFICATION is the process of recognizing classes or kinds, each class or kind consisting of members having certain characteristics in common. The members may themselves be classes or they may be individuals. In a complete system of classification the lowest classes (in which only individual members can be distinguished) are subordinated to higher ones, and these again to others still higher until the most inclusive category with which the science in question is concerned is reached. In Logic, such an inclusive category or highest class is called a *summmum genus*, and the lowest, *infima species*; each intermediate class is called a *genus* of the one below it, and a *species* of the one above. In the biological sciences the terms *genus* and *species* are not used in this relative sense, but denote certain definite classes in the biological scheme.

Classification is one method, probably the simplest method, of discovering order in the world. By noting similarities between numerous distinct individuals, and thinking of these individuals as forming one class or kind, the many are in a sense reduced to one, and to that extent simplicity and order are introduced into the bewildering multiplicity of Nature. In the history of every science classification is the very first method to be employed; but it is much older than science. Every name, indeed almost every word, of a language is the expression of some implicit classification; and language is older than science. The classifications expressed in ordinary language are, however, the result of practical needs rather than of scientific interests, so that science has to correct them even when it starts from them. The scientific classification of such things as coal, or whales, or sea-anemones, or of processes like rusting and breathing, is very different from the popular way of classing them.

Scientific classification seeks to formulate a scheme of mutually exclusive and collectively exhaustive categories based on the most important characteristics of the things concerned and on the actual relations between them. This is frequently a very difficult matter, as the history of biology shows. The more nearly a classification approaches the aforementioned ideal the better is its claim to be called a *natural* one; a classification that deviates from this ideal, as usually happens when it is made for some practical human purpose, is called *artificial* (e.g., a herbalist's classification of herbs with reference to their medicinal uses). Border cases are especially apt to cause trouble. To this day there is uncertainty whether certain micro-organisms should be classed as plants or as animals. *Volvocinae* and the *Euglena viridis*, for example, have some of the characteristics of vegetables and also some of those of animals, so they are simply listed as "organisms" for the time being.

In one sense classification is the basic method of science. For science is mainly interested in general truths, that is, in truths relating to classes of things or events rather than to individual instances. Whatever other methods it may employ in discovering a certain truth, that truth is implicitly applied at once to the whole class of phenomena to which the instance in connection with which the discovery has been made belongs. This obviously assumes a correct classification of the phenomena in question.

Some classifications are based on evidence of common descent or biological kinship. Such are known as *phylogenetic* classifications.

CLASTIDIUM (mod. CASTEGGIO), a village of the Anamares in Gallia Cispadana, on the Via Postumia, 5 m. E. of Iria (mod. Voghera) and 31 m. W. of Placentia, Italy. Here in 222 B.C. M. Claudius Marcellus defeated the Gauls and won the *spolia opima*; in 218 Hannibal took Clastidium and its stores of corn by treachery.

CLAUBERG, JOHANN (1622–1665), German philosopher, was born at Solingen, in Westphalia, and studied the Cartesian philosophy under John Raey at Leyden. He became (1649) professor of philosophy and theology at Herborn and subsequently at Duisburg, where he died. Clauberger was one of the earliest teachers of the new doctrines in Germany and an exact and methodical commentator on his master's writings. His theory of the connection between the soul and the body is in some respects analogous to that of Malebranche; but he is not therefore to be regarded as a true forerunner of Occasionalism, as he uses "Occasion" for the stimulus which directly produces a mental phenomenon, without postulating the intervention of God (H. Müller, *J. Clauberger und seine Stellung im Cartesianismus*). His view of the relation of God to his creatures is held to foreshadow the pantheism of Spinoza. All creatures exist only through the continuous creative energy of the Divine Being, and are no more independent of his will than are our thoughts independent of us. Clauberger's chief works are: *De conjunctione animae et corporis humani*; *Exercitationes centum de cognitione Dei et nostri*; *Logica vetus et nova*; *Initiatio Philosophi, seu*

Dubitatio Cartesiana; a commentary on Descartes' *Meditations*; and *Ars etymologica Teutonum*.

A collected ed. of his philosophical works was pub. at Amsterdam (1691), with life by H. C. Hennin; see also E. Zeller, *Geschichte der deutschen Philosophie seit Leibnitz* (1873).

CLAUDE, JEAN (1619–1687), French Protestant divine, was born at La Sauvetat-du-Dropt near Agen. He was professor of theology at the Protestant colleges of Nîmes and of Montauban, but lost both posts on account of his intransigence. In 1666 he became pastor at Charenton near Paris, where he engaged in controversies with Pierre Nicole (*Réponse aux deux traités intitulés la perpétuité de la foi*, 1665), Antoine Arnauld (*Réponse au livre de M. Arnauld*, 1670), and J. B. Bossuet (*Réponse au livre de M. L'évêque de Meaux*, 1683). On the revocation of the edict of Nantes he fled to Holland, and received a pension from William of Orange, who commissioned him to write an account of the persecuted Huguenots (*Plaintes des protestants cruellement opprimés dans le royaume de France*, 1686). The English translation of this book and the original were publicly burnt by the common hangman by order of James II. on May 5, 1686, as containing "expressions scandalous to His Majesty the king of France."

See biographies by J. P. Nicéron and Abel Rotholf de la Devèze; E. Haag, *La France protestante*, vol. iv. (1884 ed.).

CLAUDE LORRAIN or **CLAUDE GELLÉE** (1600–1682), French landscape-painter, was born at Chamagne in Lorraine. At the age of 12 he went to live at Freiburg in Baden with an elder brother. He afterwards went to Rome where he lived with the landscape painter, Augustin Tassi. In 1625 he travelled to Venice and through Tirol to his native country. Claude De Ruet, painter to the duke of Lorraine, kept him as assistant for a year; and he painted at Nancy the ceiling of the Carmelite church. In 1627 he returned to Rome where he earned the protection of Pope Urban VIII., and from about 1637 he rapidly rose into celebrity. Claude's landscapes are composed according to the classical traditions of the Italian school. He bathed his scenes in light and atmosphere. His figures, however, are very indifferent and he usually engaged other artists to paint them for him. In order to avoid a repetition of the same subject, and also to detect the very numerous spurious copies of his works, he made tinted outline drawings (in six paper books which he named *Libri di Verita*) of most of his pictures, with the name of the purchaser. This valuable work (now belonging to the duke of Devonshire) has been engraved and published. Claude died in Rome at the age of 82, on Nov. 21, 1682.

Many choice specimens of his genius may be seen in the National Gallery, London, in the Louvre, at the Doria palace in Rome and at private collections in Britain. The British Museum, the Louvre, and the Albertina contain fine collections of pen and ink drawings. Claude's engravings are much sought after.

CLAUDEL, PAUL (1868–), French poet, dramatist and diplomat, was born Aug. 6, 1868 at Villeneuve-sur-Fin. He was educated at the Lycée Louis-le-Grand, and entered the consular service in 1892. The early part of his diplomatic career was spent in the East as consul at Foochow, Shanghai and Tientsin. As first secretary at Peking he gained a valuable acquaintance with Chinese life and thought. In 1921 he was made French ambassador at Tokyo after a series of European appointments and three years in Rio de Janeiro.

He was subsequently appointed ambassador at Washington (1927). The store of worldly wisdom which he had acquired in the course of his official duties did much to stimulate and colour his poetry and helped to make his style among the weightiest and richest in French literature. Though trained in the school of the Symbolists, and especially of Rimbaud, Claudel breaks away from them in certain essential particulars. His fundamental inspiration is catholicism—but the catholicism is the fruit of his own meditation and is, as it were, re-created. The cosmic breadth of his views, his deep metaphysical interest and his fine treatment of

both the grandiose and the commonplace derive from his close study of Aeschylus (whose *Oresteia* he has translated) of Dante and of Holy Writ. He has created his own style, a plastic versification founded on a meticulous study of the rhythm of word and pause. Of his purely lyrical works, the following are the principal: *Cinq Grandes Odes* (1910); *Le Cantate* (1914); *Corona Benignitatis Dei* (1915); *Feuilles des Saints* (1925); but his reputation will most surely rest on his plays; those of outstanding merit are: *Tête d'or*; *La Ville*; *L'Échange*; *La Jeune Fille Violaine* (pub. in 1901 under the title *L'Arbre*)—in which the influence of the Symbolists is clearly perceptible; *L'Annonce faite à Marie* (1912) and the great trilogy in which he has attempted to reproduce the moral drama of post-revolutionary days: *L'Otage* (1911); *Le Pain Dur* (1918); *le Père Humilié* (1919). Many of Claudel's chief works have been translated into English, e.g., *Connaissance de l'Est* (by T. Frances and W. R. Benét as "The East I Know"); and *L'Annonce faite à Marie* (by L. M. Still, 1916). *The Book of Christopher Columbus* appeared in 1930.

CLAUDET, ANTOINE FRANÇOIS JEAN (1797–1867), French photographer, was born at Lyons on Aug. 12, 1797. Having acquired a share in L. J. M. Daguerre's invention, he was one of the first to practise daguerreotype portraiture in England, and he improved the sensitizing process by using chlorine in addition to iodine, thus gaining greater rapidity of action. In 1848 he produced the photographometer, an instrument designed to measure the intensity of photogenic rays; and in 1849 he brought out the focimeter, for securing a perfect focus in photographic portraiture. He was elected F.R.S. in 1853, and in 1858 he produced the stereomonoscope, in reply to a challenge from Sir David Brewster. He died in London on Dec. 27, 1867.

CLAUDIA NOVA, VIA, an ancient road of Italy, 47m. in length, connecting the Via (Claudia) Valeria with the Via Caecilia and Via Salaria at Foruli, near Amiternum and thus linking together the road systems of north and south Italy. It was built by the emperor Claudius in A.D. 47. Its course and remains, as well as the ancient towns and buildings along it, are described by R. Gardner in *Journal of Roman Studies*, iii. (1913) 205–232.

CLAUDIANUS, CLAUDIUS (Anglicized, **CLAUDIAN**), Latin epic poet during the reign of Arcadius and Honorius. He was an Egyptian by birth, probably an Alexandrian. In A.D. 395 he appears to have come to Rome, and made his debut as a Latin poet by a panegyric on the consulship of Olybrius and Probinus. (In Birt's edition a complete chronological list of Claudian's poems is given, and also in J. B. Bury's edition of Gibbon (iii. app. i. p. 485), where the dates given differ slightly from those in the present article.)

In 396 appeared the encomium on the third consulship of the emperor Honorius, and the epic on the downfall of Rufinus, the unworthy minister of Arcadius at Constantinople, which was engineered by Stilicho. Claudian's poem appears to have obtained his patronage, or perhaps that of his wife Serena (*Epist.* 2). In 398 appeared his panegyric on the fourth consulship of Honorius, his epithalamium on the marriage of Honorius to Stilicho's daughter, and his poem on the Gildonic War, celebrating the repression of a revolt in Africa. To these succeeded his piece on the consulship of Manlius Theodorus (399), the unfinished invective against the Byzantine prime minister Eutropius in the same year, the epics on Stilicho's first consulship and on his repulse of Alaric (400 and 403), and the panegyric on the sixth consulship of Honorius (404). From this time all trace of Claudian is lost, and he is generally supposed to have perished with his patron Stilicho in 408. It may be conjectured that he must have died in 404, as he could hardly otherwise have omitted to celebrate Stilicho's destruction of the barbarian host led by Radagaisus in the following year. On the other hand, he may have survived Stilicho, as in the dedication to the second book of his epic on the *Rape of Proserpine* (which Birt, however, assigns to 395–397), he speaks of his disuse of poetry. From Augustine's allusion to him in the *De civitate Dei*, it may be inferred that he was no longer living at the date of the composition of that work, between 415 and 428.

Besides Claudian's chief poems, his lively Fescennines on the

emperor's marriage, his panegyric on Serena, and the *Gigantomachia*, a fragment of an unfinished Greek epic, may also be mentioned. Several poems expressing Christian sentiments are spurious. It is probable that he was nominally a Christian, like his patrons Stilicho and Ausonius, although at heart attached to the old religion. He was honoured by a bronze statue in the forum, and Pomponius Laetus discovered in the 15th century an inscription (*C.I.L.* vi. 1710) on the pedestal, which, formerly considered spurious, is now generally regarded as genuine.

The revival of Latin poetry at so late a date, and by a poet of foreign birth is remarkable, and it is no less surprising that Claudian should have won fame by official panegyrics. As remarked by Gibbon, "he was endowed with the rare and precious talent of raising the meanest, of adorning the most barren, and of diversifying the most similar topics." This gift is especially displayed in his poem on the downfall of Rufinus. In his celebration of Stilicho's victories Claudian found a subject more worthy of his powers, and some passages, such as the description of the flight of Alaric, and of Stilicho's arrival at Rome, rank among the brightest ornaments of Latin poetry. Yet on the whole he lacks creative power, and his talent is rather that of the rhetorician than the poet.

BIBLIOGRAPHY.—The editio princeps of Claudian was printed at Vicenza in 1482; the editions of J. M. Gesner (1759) and P. Burmann (1760) are still valuable for their notes. The first critical edition was that of L. Jeep (1876–79), now superseded by the exhaustive work of T. Birt, with bibliography, in *Monumenta Germaniae Historica* (x., 1892; smaller ed. founded on this by J. Koch, Teubner series, 1893). Edition with English translation by Platnauer (Loeb series, 1922). There is a separate edition with commentary and verse translation of *Il Ratto di Proserpina*, by L. Garces de Diez (1889); the satire *In Eutropium* is discussed by T. Birt in *Zwei politische Satiren des alten Rom* (1888). There is a complete English verse translation of little merit by A. Hawkins (1817). See the articles by Ramsay in Smith's *Classical Dictionary* and Vollmer in Pauly-Wissowa's *Realencyclopädie der classischen Altertumswissenschaft*, iii. 2 (1899); also J. H. E. Cress, *Claudian as an Historian* (1908), the "Cambridge Historical Essay" for 1906 (No. 17); T. Hodgkin, *Claudian, the last of the Roman Poets* (1875). H. Schöff, *Claudians Gedicht vom Gotenkrieg* (1927) with bibliography.

CLAUDIUS, the name of a famous Roman gens. The by-form *Clodius* was regularly used for certain Claudii in late republican times, but otherwise the two forms were used indifferently. The gens contained a patrician and a plebeian family; the chief representatives of the former were the Pulchri, of the latter the Marcelli (see MARCELLUS). The following members deserve particular mention:—

1. **APPIUS SABINUS INREGILLENIS, or REGILLENIS, CLAUDIUS**, so called from Regillum (or Regilli) in Sabine territory, founder of the Claudian gens. His original name was Attus or Attius Clausus. About 504 B.C. he settled in Rome, where he and his followers formed a tribe. In 495 he was consul, and his enforcement of the laws of debt was one of the chief causes of the "secession" of the plebs to the Sacred Mount. See Suetonius, *Tiberius*, i.; Livy ii. 16–29; Dion. Halic. v. 40, vi. 23, 24.

2. **CLAUDIUS, APPIUS**, surnamed **CRASSUS**, a Roman patrician, consul in 471 and 451 B.C., and in the same and following year one of the decemvirs. At first he was conspicuous for his aristocratic pride and bitter hatred of the plebeians. Twice they refused to fight under him, and fled before their enemies. He retaliated by decimating the army. He was banished, but soon returned, and again became consul. In the same year (451) he was made one of the decemvirs who had been appointed to draw up a code of written laws. He managed, by courting the people, to secure his re-election for the year 450, and the new decemvirs, under his leadership, began a reign of terror. Matters were brought to a crisis by the affair of Virginia, the daughter of Virginius, a plebeian centurion. Claudius, desiring to possess her, got a client to swear falsely that she was the child of his slave, and judgment was given in his favour. To save her, Virginius killed her with his own hand. An insurrection was the result, and the people seceded to the Sacred Mount. The decemvirs were finally compelled to resign and Appius Claudius died in prison, either by his own hand or by that of the executioner. For a discussion of the character of Appius Claudius, see Mommsen's appendix to vol. i.

of his *History of Rome*, also Livy iii. 32-58; Dion. Halic. x. 59, xi. 3.

3. **CLAUDIUS, APPIUS**, surnamed **CAECUS**, Roman patrician and author. In 312 B.C. he was elected censor without having been consul. During his censorship, which he retained for five years, in spite of the *lex Aemilia* which limited the tenure of that office to 18 months, he filled vacancies in the senate with men of low birth, in some cases even the sons of freedmen (Diod. Sic. xx. 36; Livy ix. 30; Suetonius, *Claudius*, 24). He abolished the old free birth, freehold basis of suffrage. He enrolled the freedmen and landless citizens both in the centuries and in the tribes, distributing them through all the tribes and thus giving them practical control of the elections. In 304, however, the landless and poorer freedmen were limited to the four urban tribes, and the effect of Claudius's arrangement was annulled. Appius Claudius transferred the charge of the public worship of Hercules in the Forum Boarium from the Potitian gens to a number of public slaves. He further invaded the exclusive rights of the patricians by directing his secretary to publish the *legis actiones* (methods of legal practice) and the list of *dies fasti* (or days on which legal business could be transacted). Lastly, he gained enduring fame by the construction of a road and an aqueduct, which—a thing unheard of before—he called by his own name (Livy, ix. 29; Frontinus, *De Aquis*, 115; Diod. Sic. xx. 36). In 307 he was elected consul for the first time. In 298 he was interrex; in 296, as consul, he led the army in Samnium (Livy, x. 19). During the next year he was praetor, and he was once dictator. In spite of his political reforms, he opposed the admission of the plebeians to the consulship and priestly offices; his probable aim was to strengthen the power of the magistrates and lessen that of the senate. He was already blind and too feeble to walk, when Cineas, the minister of Pyrrhus, visited him, but so vigorously did he oppose every concession that all the eloquence of Cineas was in vain, and the Romans forgot past misfortunes in the inspiration of Claudius's patriotism (Livy, x. 13; Justin, xviii. 2; Plutarch, *Pyrrhus*, 19). The story of his blindness, however, may be merely a method of accounting for his cognomen. Tradition regarded it as a punishment for his transference of the cult of Hercules from the Potitii.

His speech against peace with Pyrrhus was the first that was transmitted to writing, and thereby laid the foundation of prose composition. He was the author of a collection of aphorisms in verse mentioned by Cicero (of which a few fragments remain), and of a legal work entitled *De Usurpationibus*. It is very likely also that he was concerned in the drawing up of the *Legis Actiones* published by Flavius. He also interested himself in grammatical questions, distinguished the two sounds R and S in writing, and did away with the letter Z.

See Mommsen's appendix to his *Roman History* (vol. i.); treatises by W. Siebert (1863) and F. D. Gerlach (1872), dealing especially with the censorship of Claudius.

4. **CLAUDIUS, PUBLIUS**, surnamed **PULCHER**, son of (3). He was the first of the gens who bore this surname. In 249 he was consul and appointed to the command of the fleet in the first Punic War. Instead of continuing the siege of Lilybaeum, he decided to attack the Carthaginians in the harbour of Drepanum, and was completely defeated. The disaster was commonly attributed to Claudius's treatment of the sacred chickens, which refused to eat before the battle. "Let them drink then," said the consul, and ordered them to be thrown into the sea. Having been recalled and ordered to appoint a dictator, he nominated a subordinate official, but the nomination was at once overruled. Claudius himself was accused of high treason and heavily fined. He must have died before 246, probably by his own hand. See Livy, *Epit.*, 19; Polybius, i. 49; Cicero, *De Divinatione*, i. 16, ii. 8; Valerius Maximus, i. 4, viii. 1.

5. **CLAUDIUS APPIUS**, surnamed **PULCHER**, Roman statesman and author. He served under his brother-in-law Lucullus in Asia (72 B.C.) and was commissioned to deliver the ultimatum to Tigranes, which gave him the choice of war with Rome or the surrender of Mithradates. In 57 he was praetor, in 56 propraetor in Sardinia, and in 54 consul with L. Domitius Ahenobarbus.

Pompey reconciled him to Cicero, whose return from exile he had opposed. In 53 he became governor of Cilicia. During this period he carried on a correspondence with Cicero, whose letters to him form the third book of the *Epistolae ad Familiares*. Claudius resented the appointment of Cicero as his successor, avoided meeting him, and issued orders after his arrival in the province. On his return to Rome Claudius was impeached by P. Cornelius Dolabella, and was obliged to make advances to Cicero, since it was necessary to obtain witnesses in his favour from his old province. He was acquitted, and a charge of bribery against him also proved unsuccessful. In 50 he was censor, and expelled many of the members of the senate. When Caesar marched on Rome he fled from Italy. He was appointed by Pompey to the command in Greece, and died in Euboea about 48, before the battle of Pharsalus. He wrote a work on augury, the first book of which he dedicated to Cicero. See Orelli, *Onomasticon Tullianum*.

BIBLIOGRAPHY.—A full account of all the Claudii will be found in Pauly-Wissowa's *Realencyclopädie der classischen Altertumswissenschaft*, iii. 2 (1899). See also L. A. Constans, *Un Correspondant de Cicéron, Ap. Claudius Pulcher* (1921).

CLAUDIUS (TIBERIUS CLAUDIUS DRUSUS NERO GERMANICUS), Roman emperor A.D. 41-54, son of Drusus and Antonia, nephew of the Emperor Tiberius, and grandson of Livia, the wife of Augustus, was born at Lugdunum (Lyons) on Aug. 1, 10 B.C. He was kept in the background by (Suet. *Claud.* 4) Augustus Tiberius, owing to his physical infirmities and apparent weakness of intellect, and lived in retirement; it was probably at this time that he became dependent on the company of freedmen. Under Caligula he became more prominent, holding the consulship (A.D. 37) and other public posts; though he was the emperor's butt, many people at Rome must have realized that he might succeed. On the murder of Caligula, Claudius, though not of the Julian gens, was made emperor by the praetorians, who were rewarded with a large donative, and were probably increased in number.

Claudius, though abnormal, was by no means the idiot that our hostile sources would suggest. Despite his pedantry, he had a certain shrewdness, and wished to govern well. In the earlier part of his reign he extended the boundaries of the empire; Mauretania was subdued and annexed in 43, and in the same year Claudius himself took part in the famous expedition to Britain, which gave the Romans a footing in the south of the island; in 44 Judea, which had been entrusted to King Agrippa (q.v.), was made once more a province, and in 46 the same fate overtook the client kingdom of Thrace.

In his dealings with the provincials Claudius, despite senatorial opposition, reverted to Julius Caesar's liberal policy. We possess part of his speech proposing that the chieftains of the Aedui should be admitted to the senate (see the paraphrase of it in Tacitus *Annals*), and his edict conferring citizenship on the Anauni (Hardy, *Roman Laws and Charters* Oxford, 1912). A large number of municipia and colonies in the provinces owe their origin to Claudius.

The reign of Claudius is marked by the development of the emperor's personal service. There was an extension of procuratorial government in the provinces (e.g., Thrace, Mauretania, and Judea) and provincial procurators were granted jurisdiction equal to that of the emperor in all cases relating to the fiscus. A definite scale of salaries was also instituted. But even more notable was the increased power of the emperor's freedmen, who, while they remained his personal servants, became, in practice, powerful ministers, and received great rewards and honour. (See, besides authorities below, Statius, *Silv.* iii. and v.) The rule of the freedmen, who, though efficient, were arrogant and corrupt, was resented by the nobility, but the practice was continued under later emperors, though not to the same extent.

Another grievance was the increased importance of the emperor's private court. Under Augustus and Tiberius its use had been restricted to certain cases of *majestas*, but Claudius had a passion for acting as judge; vast numbers of cases were heard *in camera*, and the emperor's methods seem often to have been capricious.

His public works include a new harbour at Ostia, the draining of the Fucine Lake, and the construction of two aqueducts (*Aqua*

Claudia and *Anio Novus*). His revival of the censorship and extension of the pomerium may be quoted rather as examples of his antiquarianism than as practically important. In 47 he celebrated the *Ludi Saeculares*.

In the latter part of his reign his government degenerated and he fell entirely under the influence of his favourites and his womenkind.

He had married (as his third wife) Messalina, who, in 47, if we are to believe Tacitus, actually went through a form of marriage with Silius, unknown to Claudius. Narcissus brought about her execution, and, at the prompting of Pallas, the *a nationibus*, Claudius married his niece Agrippina, a marriage which shocked Roman sentiment. She induced him to set aside his own son Britannicus and to adopt as heir Nero, her son by a former marriage. Claudius died suddenly in 54, poisoned, according to Tacitus, by Agrippina. He was deified, but Seneca's satire, the *Apocolocyntosis*, expresses the relief felt at his death.

Claudius wrote several historical works "magis inepte quam inelegeranter," including his own autobiography, but all, unfortunately, are lost.

CLAUDIUS, MARCUS AURELIUS, surnamed **GOTHICUS**, Roman emperor A.D. 268–270, belonged to an obscure Illyrian family. On account of his military ability he was placed in command of an army by Decius; and Valerian appointed him general on the Illyrian frontier, and ruler of the provinces of the lower Danube. During the reign of Gallienus, he was called to Italy to crush Aureolus, and on the death of the emperor (268) was chosen as his successor. Shortly after his accession he routed the Alamanni on the Lacus Benacus (some doubt is thrown upon this); in 269 a great victory over the Goths at Naissus in Moesia gained him the title of Gothicus. In the following year he died of the plague at Sirmium. He enjoyed great popularity, and appears to have been a man of ability and character.

His life was written by Trebellius Pollio, one of the *Scriptores Historiae Augustae*; see also Zosimus i. 40–43; Homo, *De Claudio Gothico* (1900); Pauly-Wissowa, *Realencyklopädie*, ii. 2458 et seq. (Henze).

CLAUDIUS, MATTHIAS (1740–1815), German poet, otherwise known by the *nom de plume* of Asmus, was born on Aug. 15, 1740, at Rheinfeld, near Lübeck, and studied at Jena. From 1771 to 1775 he edited a newspaper called the *Wandsbecker Bote* (*Wandsbeck Messenger*), in which he published a large number of prose essays and poems. He died on Jan. 21, 1815. In his later days Claudius became strongly pietistic.

BIBLIOGRAPHY.—Claudius's collected works were published under the title of *Asmus omnia sua seculum portans, oder Sämtliche Werke des Wandsbecker Boten* (8 vols., 1775–1812; 13th ed., by C. Redich, 2 vols., 1902). His biography has been written by Wilhelm Herbst (4th ed., 1878). See also M. Schneider, *M. Claudius, seine Weltanschauung und Lebensweisheit* (1898).

CLAUS, ÉMILE (1849–1924), Belgian painter, was born at Vive Saint-Éloi, Flanders, on Sept. 27, 1849. Receiving early training at the Antwerp Academy of Fine Arts, Claus began as a traditionalist. Soon, however, he came under the influence of certain French painters who had determined to break from the rut, and he completely changed his style, in spite of the fact that he had achieved a certain reputation and his work was remunerative. He started to paint in high lights by the juxtaposition of pure colours. He settled at Astène, in a house on the banks of the Lys, which he called *Zonneschijn*. There he began

to paint that beautiful series of views of meadows, gardens, fields, streams and roads.

During the World War Claus resided in London, and from the windows of a house on the Victoria Embankment painted views of the Thames, showing the changing effects of the light and the weather. In 1917 he accompanied the Queen of the Belgians to La Panne, and visited the devastated regions. In 1920 he returned to Astène and worked there until his death, on June 6, 1924. He was the recipient of numerous Belgian and foreign honours. He is represented in the Luxembourg, Paris, and in galleries in Venice, Brussels, Antwerp, Ghent and Liège.

CLAUSEL (more correctly **CLAUZEL**), **BERTRAND**, **COUNT** (1772–1842), marshal of France, was born at Mirepoix (Ariège) on Dec. 12, 1772, and served in the first campaign of the French Revolutionary Wars as one of the volunteers of 1791. In June 1795, having distinguished himself repeatedly in the war on the northern frontier (1792–93) and the fighting in the eastern Pyrenees (1793–94), Clausel was made a general of brigade. In this rank he served in Italy in 1798 and 1799, in the expedition to S. Domingo in 1802, in Naples in 1806. In 1808–09 he was with Marmont in Dalmatia, and at the close of 1809 he was appointed to a command in the army of Portugal under Massena.

Clausel took part in the Peninsular campaigns of 1810 and 1811, including the Torres Vedras campaign, and under Marmont he did excellent service in re-establishing the discipline, efficiency, and mobility of the army. In the Salamanca campaign (1812) the result of Clausel's work was shown in the marching powers of the French, and at the battle of Salamanca, Clausel, who had succeeded to the command on Marmont being wounded, and had himself received a severe wound, drew off his army with the greatest skill. Early in 1813 Clausel was made commander of the army of the north in Spain, but he was unable to avert the great disaster of Vittoria. Under the supreme command of Soult he served through the rest of the Peninsular War with unvarying distinction. During the Hundred Days he was in command of an army defending the Pyrenean frontier. After Waterloo he escaped to America, being condemned to death in absence. He took the first opportunity of returning to aid the Liberals in France (1820), sat in the chamber of deputies from 1827 to 1830, and after the revolution of 1830 was at once given a military command. At the head of the army of Algiers, Clausel made a successful campaign, but he was soon recalled by the home government, which desired to avoid complications in Algeria. At the same time he was made a marshal of France (Feb. 1831). For some four years thereafter he urged his Algerian policy upon the chamber of deputies, and finally in 1835 was reappointed commander-in-chief. But after several victories, including the taking of Mascara in 1835, the marshal met with a severe repulse at Constantine in 1836. A change of government in France was primarily responsible for the failure, but public opinion attributed it to Clausel, who was recalled in Feb. 1837. He thereupon retired from active service and lived in complete retirement up to his death at Secourrieu (Garonne) on April 21, 1842.

CLAUSEN, SIR GEORGE (1852–), English painter, born in London, the son of a decorative artist. He attended the design classes at the South Kensington schools from 1867–73 with great success. He then worked in the studio of Edwin Long, R.A., and subsequently in Paris under Bouguereau and Robert-Fleury. His "Girl at the Gate" was acquired for the nation by the Chantrey Trustees and placed in the Tate gallery. He became R.A. in 1908 and was knighted in 1927. His series of lectures to the students of the Royal Academy schools was published as *Six Lectures on Painting* (1904), and *Aims and Ideals in Art* (1906).

CLAUSEWITZ, KARL VON (1780–1831), Prussian general and military writer, was born at Burg, near Magdeburg, on June 1, 1780. His family, originally Polish, had settled in Germany at the end of the previous century. Entering the army in 1792, he first saw service in the Rhine campaigns of 1793–94, receiving his commission at the siege of Mainz. On his return to garrison duty he set to work so zealously to remedy the defects in his education caused by his father's poverty, that in 1801 he was admitted to the Berlin academy for young officers, then

directed by Scharnhorst. Scharnhorst, attracted by his pupil's industry and force of character, paid special attention to his training, and profoundly influenced the development of his mind. In 1803, on Scharnhorst's recommendation, Clausewitz was made "adjutant" (aide-de-camp) to Prince August, and he served in this capacity in the campaign of Jena (1806), being captured along with the prince by the French at Prenzlau. A prisoner in France and Switzerland for the next two years, he returned to Prussia in 1809; and for the next three years, as a departmental chief in the ministry of war, as a teacher in the military school, and as military instructor to the crown prince, he assisted Scharnhorst in the famous reorganization of the Prussian Army. In 1810 he married the countess Marie von Brühl.

On the outbreak of the Russian war in 1812, Clausewitz, like many other Prussian officers, took service with his country's nominal enemy. This step he justified in a memorial, published for the first time in the *Leben Gneisenaus* by Pertz (1869). At first adjutant to Gen. Phull, who had himself been a Prussian officer, he served later under Pahlen at Witepsk and Smolensk, and from the final Russian position at Kaluga he was sent to the army of Wittgenstein. It was Clausewitz who negotiated the convention of Tauroggen, which separated the cause of Yorck's Prussians from that of the French, and began the War of Liberation (see YORCK VON WARTENBURG; also Blumenthal's *Die Konvention von Tauroggen*, 1901). As a Russian officer he superintended the formation of the *Landwehr* of east Prussia (see STEIN, H. F. K.), and in the campaign of 1813 he served as chief of staff to Count Wallmoden. He conducted the fight at Göhrde, and after the armistice, with Gneisenau's permission, published an account of the campaign (*Der Feldzug von 1813 bis zum Waffenstillstand*, Leipzig, 1813). This work was long attributed to Gneisenau himself. After the peace of 1814 Clausewitz re-entered the Prussian service, and in the Waterloo campaign was present at Ligny and Wavre as Gen. Thielmann's chief of staff. This post he retained till 1818, when he was promoted major-general and appointed director of the *Allgemeine Kriegsschule*. Here he remained till in 1830 he was made chief of the 3rd Artillery Inspection at Breslau. Next year he became chief of staff to Field-marshal Gneisenau, who commanded an army of observation on the Polish frontier. After the dissolution of this army Clausewitz returned to his artillery duties; but on Nov. 18, 1831, he died at Breslau of cholera, which had proved fatal to his chief also, and a little previously, to his old Russian commander Diebitsch on the other side of the frontier.

His collected works were edited and published by his widow, who was aided by some officers, personal friends of the general, in her task. Of the ten volumes of *Hinterlassene Werke über Krieg und Kriegführung* (1832-37, later edition called *Clausewitz's Gesammte Werke*, 1874) the first three contain Clausewitz's masterpiece, *Vom Kriege*, an exposition of the philosophy of war. He produced no "system" of strategy, and his critics styled his work "negative" and asked "*Qu'a-t-il fondé?*" What he had "founded" was that modern strategy which, by its hold on the Prussian mind, carried the Prussian arms to victory in 1866 and 1870, and his philosophy of war became, not only in Germany but in many other countries, the basis of military studies. But it has been argued since the World War that his teaching contributed to the deadlock and costly attrition strategy of 1914-18 through its excessive emphasis on purely military factors, a tendency naturally exaggerated by his disciples. The English and French translations (Graham, *On War*, 1873; Neuen, *La Guerre*, 1849-52; or Vetry, *Théorie de la grande guerre*, 1899), with the German original, place the work at the disposal of students of most nationalities. The remaining volumes deal with military history: vol. 4, the Italian campaign of 1796-97; vols. 5 and 6, the campaign of 1799 in Switzerland and Italy; vol. 7, the wars of 1812, 1813 to the armistice, and 1814; vol. 8, the Waterloo campaign; vols. 9 and 10, papers on the campaigns of Gustavus Adolphus, Turenne, Luxemburg, Münnich, John Sobieski, Frederick the Great, Ferdinand of Brunswick, etc. He also wrote *Über das Leben und den Charakter von Scharnhorst* (printed in Ranke's *Historisch-politischer Zeitschrift*, 1832).

A manuscript on the catastrophe of 1806 long remained unpublished. It was used by v. Höpfner in his history of that war, and eventually published by the Great General Staff in 1888 (French translation, 1903). Letters from Clausewitz to his wife were published in *Zeitschrift für preussische Landeskunde* (1876).

See von Meerheimb, *Karl von Clausewitz* (1875), also Memoir in *Allgemeine deutsche Biographie*; Schwartz, *Leben des General von Clausewitz und der Frau Marie von Clausewitz* (2 vols., 1877); Bernhardt, *Leben des Generals von Clausewitz* (10th Supplement, *Militär. Wochenblatt*, 1878).

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

THE CLAVICEMBALO, AN ITALIAN HARPSICHORD OF THE 16TH CENTURY

CLAUSIUS, RUDOLF JULIUS EMMANUEL (1822-1888), German physicist, was born at Köslin, in Pomerania. After attending the Gymnasium at Stettin, he studied at Berlin university from 1840 to 1844. In 1848 he took his degree at Halle, and in 1850 was appointed professor of physics in the royal artillery and engineering school at Berlin and *privatdocent* in the university. In 1855 he became an ordinary professor at Zürich Polytechnic, and professor in the University of Zürich. In 1867 he moved to Würzburg as professor of physics, and two years later was appointed to the same chair at Bonn, where he died. The work of Clausius, who was a mathematical rather than an experimental physicist, was concerned with many of the most abstruse problems of molecular physics. By his restatement of Carnot's principle he put the theory of heat on a truer and sounder basis, and he deserves the credit of having made thermodynamics a science; he enunciated the second law, in a paper contributed to the Berlin Academy in 1850, in the well-known form, "Heat cannot of itself pass from a colder to a hotter body." His results he applied to an exhaustive development of the theory of the steam-engine, laying stress in particular on the conception of entropy. The kinetic theory of gases owes much to his researches. He raised it, on the basis of the dynamical theory of heat, to the level of a theory, and he carried out many numerical determinations in connection with it, e.g., of the mean free path of a molecule. Clausius also made an important advance in the theory of electrolysis, suggesting that molecules in electrolytes are continually interchanging atoms, the electric force not causing, but merely directing the interchange. This view found little favour until 1887, when it was taken up by S. A. Arrhenius, who made it the basis of the theory of electrolytic dissociation. In addition to many scientific papers he wrote *Die Potentialfunktion und das Potential* (1864) and *Abhandlungen über die mechanische Wärmetheorie* (1864-67).

CLAVECIN, the French for "clavicymbal" or "harpsichord" (Ger. *Clavicymbel* or *Dockenklavier*), an abbreviation of the

Flemish *clavisinbal* and Ital. *clavicimbalo*. See PIANOFORTE; HARPSICHORD; SPINET; VIRGINAL.

CLAVICEMBALO or **GRAVICEMBALO**, the Italian names for the clavicymbal or harpsichord. "Cymbal" (Gr. *κύμβαλον*, from *κύμβη*, a hollow vessel) was the old European term for the dulcimer, and hence its place in the formation of the word. See PIANOFORTE; HARPSICHORD; SPINET; VIRGINAL.

CLAVICHORD or **CLARICHORD**, a mediaeval stringed keyboard instrument, a forerunner of the pianoforte (*q.v.*), its

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

THE MEDIAEVAL CLAVICHORD, A FORERUNNER OF THE PIANO
This instrument differed from the harpsichord in that its strings were struck by tangents, instead of being plucked or twanged by quills. Its tone, though weak, was very delicate and sweet

strings being set in vibration by a blow from a brass tangent instead of a hammer as in the modern instrument.

The clavichord, derived from the dulcimer by the addition of a keyboard, has a long history, being mentioned as early as 1404 in Eberhard Cersne's *Rules of the Minnesingers*.

There were two kinds of clavichords—the fretted or *gebunden* and the fret-free or *bund-frei*. The term "fretted" was applied to those clavichords which, instead of being provided with a string or set of strings in unison for each note, had one set of strings acting for three or four notes, the arms of the keys being twisted in order to bring the contact of the tangent into the acoustically correct position under the string. The "fret-free" were chromatically-scaled instruments.

The first *bund-frei* clavichord is attributed to Daniel Faber of Crailsheim in Saxony about 1720. This important change in construction increased the size of the instrument, each pair of unison strings requiring a key and tangent of its own, and led to the introduction of the system of tuning by equal temperament upheld by J. S. Bach and practically illustrated by him in his immortal "Wohltemperirtes Clavier" ("Well-tempered Clavier") written expressly to encourage its adoption.

The tone of the clavichord, extremely sweet and delicate, was characterized by a tremulous hesitancy, which formed its great charm, though its very limited power rendered it unsuitable for use in large rooms or concert halls. Nevertheless, on account of the scope which it afforded for individual expression, it was a favourite instrument with all the best musicians in its day. Bach is said to have preferred it to the harpsichord, Mozart loved to play on it, while even Beethoven, though himself long accustomed to the pianoforte, spoke of it as the most expressive of all keyboard instruments.

CLAVICYTHERIUM, a name usually applied to an upright spinet (*q.v.*), the soundboard and strings of which were

vertical instead of horizontal, being thus perpendicular to the keyboard; but it would seem that the clavicitherium proper is distinct from the upright spinet in that its strings are placed *horizontally*. In a unique specimen with two keyboards dating from the 16th or 17th century, which is in the collection of Baron Alexandre Kraus, what appear to be vibrating strings stretched over a soundboard perpendicular to the keyboard are in reality the wires forming part of the mechanism of the action. The instrument was probably of Italian or possibly South German origin and it may be noted that its name has also been applied at times to the upright harpsichord.

There is a very fine specimen of the so-called clavicitherium (really an upright spinet) in the Donaldson museum of the Royal College of Music, London, acquired from the Correr collection at Venice in 1885.

For the history of the clavicitherium considered as a forerunner of the pianoforte, see PIANOFORTE.

CLAVIE, BURNING THE, an ancient Scottish custom still observed at Burghead, a fishing village on the Moray firth, near Forres. The "clavie" is a bonfire of casks split in two, lighted on Jan. 12, corresponding to the New Year of the old calendar. One of these casks is joined together again by a huge nail (Lat. *clavus*; hence the term). It is then filled with tar, lighted and carried flaming round the village, and finally up to a headland upon which stands the ruins of a Roman altar, locally called "the Douro." It here forms the nucleus of the bonfire, which is built up of split casks. When the burning tar-barrel falls in pieces the people scramble to get a lighted piece with which to kindle the New Year's fire on their cottage hearth. The charcoal of the clavie is collected and is put in pieces up the cottage chimneys to keep spirits and witches from coming down.

CLAVIÈRE, ÉTIENNE (1735–1793), French financier and politician, was born in Geneva on Jan. 27, 1735. He was a political refugee in England, and in 1789 went to France, where he assisted Mirabeau on the *Courrier de Provence* and in the preparation of his speeches. Clavière also published some pamphlets under his own name, and through these and his friendship with J. P. Brissot, whom he had met in London, he became minister of finance in the Girondist ministry, from March to June 12, 1792. After Aug. 10 he was again given charge of the finances in the provisional executive council. He shared in the fall of the Girondists, and was arrested on June 2, 1793. On receiving notice (Dec. 8) that he was to appear on the next day before the revolutionary tribunal, he committed suicide.

CLAVIJO, RUY GONZALEZ DE (d. 1412), Spanish traveller, was born in Madrid. On the return of the Embassy from the court of Timur, Henry III. of Castille sent out another, which included Clavijo. They sailed from St. Mary Port, near Cadiz, on May 22, 1403, touched at the Balearic isles, Gaeta, Rhodes and Constantinople, went by the south coast of the Black sea to Trebizond, and proceeded inland by Erzerum, Tabriz, Teheran and Meshed to Samarkand, where they were favourably received. They returned successfully after great difficulties and reached Spain on March 1, 1406. Clavijo lived in Madrid and died on April 2, 1412. His narrative is the first important one of its kind in Spanish literature.

BIBLIOGRAPHY.—An English version of Clavijo's narrative, by Sir Clements Markham, was issued by the Hakluyt Society in 1859 (*Narrative of the Embassy of R . . . G . . . Clavijo to the Court of Timour*). For the identification of the places mentioned by Clavijo see Khanikof's list in *Geographical Magazine* (1874), and Sreznevski's *Annotated Index* in the Russian edition of 1881. A short account of Clavijo's life is given by Alvarez y Baena in the *Hijos de Madrid*, vol. ix. See also C. R. Beazley, *Dawn of Modern Geography*, iii.

CLAVIJO Y FAJARDO, JOSÉ (1726–1806), Spanish publicist, was born at Lanzarote (Canary islands). He settled in Madrid, became editor of *El Pensador*, and by his campaign against the public performance of *autos sacramentales* secured their prohibition in 1765. His work would long since have been forgotten were it not that it put an end to a peculiarly national form of dramatic exposition, and that his love affair with one of Beaumarchais' sisters suggested the theme of Goethe's first publication, *Clavijo*.

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

A 17TH CENTURY ITALIAN CLAVICYTHERIUM, OR CLAVIHARP, A VERTICAL SPINET

CLAVILUX, a keyed projection instrument which makes possible the use of light as a medium for aesthetic expression. It was invented by the American artist, Thomas Wilfred, who gave the new art of light its first comprehensible status with the theory that form, colour and motion are its three basic factors. The instrument consists of a number of projectors grouped before a large white screen and controlled from a keyboard that is either attached to the projectors or placed at a distance. The keys, which slide in grooves graduated from 0 to 100, are grouped in tiers, each comparable to a pipe-organ manual. A tier contains three sets of keys connected with the form, colour and motion-producing devices in the corresponding projector in which a strong beam of white light from an incandescent lamp, after passing through the three devices, is projected on the screen as one or more mobile images depending in form, colour and motion upon the positions and movements of the various keys. A skilled player may select to play a silent visual composition previously written by another artist and recorded by means of a special notation system. The instrument has also been used for visual accompaniments to music, dance and drama, in the latter instance permitting projected scenery and a much more delicate control of lighting than is possible by means of the electrician's switchboard. (T. WI.)

CLAY, CASSIUS MARCELLUS (1810-1903), American politician, was born in Madison county, Ky., on Oct. 19, 1810. He was the son of Green Clay (1757-1826), a Kentucky soldier of the War of 1812 and a relative of Henry Clay. He was educated at Centre college, Danville, Ky., and at Yale, where he graduated in 1832. Influenced to some extent by William Lloyd Garrison, he became an advocate of the abolition of slavery. In 1835, 1837 and 1840 he was elected as a Whig to the Kentucky legislature, where he advocated a system of gradual emancipation. In 1845 he established, at Lexington, Ky., an anti-slavery publication known as *The True American*, but in the same year his office and press were wrecked by a mob, and he removed the publication office to Cincinnati, Ohio. In 1856 he joined the Republican Party, and wielded considerable influence as a Southern representative in its councils. In 1861 he was sent by President Lincoln as minister to Russia; in 1862 he returned to America to accept a commission as major-general of volunteers, but in 1863 was re-appointed to his former post at St. Petersburg, where he remained until 1869. Disapproving of the Republican policy of reconstruction, he left the party, and in 1872 was largely instrumental in securing the nomination of Horace Greeley for the presidency. In the political campaign of 1884 he rejoined the Republican Party. He died at Whitehall, Ky., on July 22, 1903.

See his autobiography, *The Life, Memoirs, Writings and Speeches of Cassius Marcellus Clay* (Cincinnati, 1896); and *The Writings of Cassius Marcellus Clay* (edited with a "Mémoir" by Horace Greeley, 1848).

CLAY, CHARLES (1801-1893), English surgeon, was born at Bredbury, near Stockport, on Dec. 27, 1801. He qualified at Edinburgh in 1823 and settled in Manchester as a consultant in 1839. In 1842 he first performed the operation of ovariectomy with which his name is associated, and in 1865 was able to show an analysis of 111 cases with a mortality slightly over 30%. Clay was a man of many interests and included geology, numismatics and book collecting among his pursuits. He died at Poulton-le-Fylde, near Preston, on Sept. 19, 1893.

CLAY, FREDERIC (1838-1889), English musical composer, was the son of James Clay, M.P., the celebrated whist authority. Born in Paris, he studied music under W. B. Molique in that city and under Moritz Hauptmann at Leipzig. With the exception of a few songs and two cantatas, *The Knights of the Cross* (1866) and *Lalla Rookh* (1877),—the latter of which contained his well-known song "I'll sing thee songs of Araby,"—his compositions were written for the stage, and have long since been forgotten. Two of them, *Ages Ago* (1869) and *Princess Toto* (1875) were written to libretti by W. S. Gilbert. Clay's last works, *The Merry Duchess* (1883) and *The Golden Ring* (1883), showed an advance upon his previous work, and rendered all the more regrettable the stroke of paralysis which crippled him physically and mentally during the last few years of his life.

CLAY, HENRY (1777-1852), American statesman and orator, was born in Hanover county, Va., on April 12, 1777, and died in Washington on June 29, 1852. His public life covered nearly half a century, and his name and fame rest entirely upon his own merits. He achieved his success despite serious obstacles. He was tall, rawboned and awkward; his early instruction was scant; but he read books, talked well, studied law under George Wythe, the teacher of Jefferson and Marshall, and so, after his admission to the bar at Richmond, Va., in 1797 and his removal next year to Lexington, Ky., he quickly acquired a reputation and a lucrative income from his law practice.

Thereafter, until the end of life, and in a field where he met, as either friend or foe, John Quincy Adams, Gallatin, Madison, Monroe, Webster, Jackson, Calhoun, Randolph and Benton, his political activity was wellnigh ceaseless. At the age of 22 (1799) he was elected to a constitutional convention in Kentucky; at 26, to the Kentucky legislature; at 29, while yet under the age limit of the U.S. Constitution, he was appointed to an unexpired term (1806-7) in the U.S. Senate, where, contrary to custom, he at once plunged into business as though he had been there all his life. He again served in the Kentucky legislature (1808-9), was chosen speaker of its lower house, and achieved distinction by preventing an intense and widespread anti-British feeling from excluding the common law from the Kentucky code. A year later he was elected to another unexpired term in the U.S. Senate, serving in 1810-11. At 34 (1811) he was elected to the U.S. House of Representatives and chosen speaker on the day of his entrance. During the 14 years following his first election, he was re-elected five times to the House and to the speakership; retiring for one term (1821-23) to resume his law practice and retrieve his fortunes. He thus served as speaker in 1811-14, in 1815-20 and in 1823-25. Once he was unanimously elected by his constituents, and once nearly defeated for having at the previous session voted to increase congressional salaries. From 1825 to 1829 he served as secretary of State in President John Quincy Adams's cabinet, and in 1831 he was elected to the U.S. Senate, where he served until 1842, and again from 1849 until his death. Between 1824 and 1848 he was a strong presidential candidate in nearly every campaign.

One of the chief sources of Clay's immediate popularity when first elected to the House in 1811, was his championship of the War of 1812 with Great Britain, which his influence, more than that of any other man, precipitated. While not, perhaps, an altogether advantageous or necessary war, it won the youthful nation the respect of European nations, and a greater independence of them than she had hitherto known. Clay was sent to Ghent as one of the peace commissioners, and signed the treaty, though reluctantly, for he was disappointed in the silence concerning the questions of impressment of American sailors, the fisheries, and the navigation of the Mississippi.

After the war Clay and Calhoun became the foremost champions of the Democratic Republican Party in Congress. Clay refused appointments as minister to Russia and to England, as well as the secretaryship of war under both Madison and Monroe that he might devote his attention to his congressional programme, the three most important features of which were the inauguration of internal improvements, the establishment of a national bank, and the levying of a tariff high enough to build up industries needed in time of war. As a protectionist Clay in 1824 again advocated high duties to relieve the prevailing distress, which he pictured in a brilliant and effective speech. In spite of the opposition of Webster, Calhoun and other prominent statesmen, Clay succeeded in enacting a tariff so high that the people of the Southern States denounced it as a "tariff of abominations." When it overswelled the revenue in 1832 he favoured reducing the rates on all articles not competing with American products, but the new measure reduced the revenue so little and provoked such serious threats of nullification and secession in South Carolina, that to prevent bloodshed and to forestall a free trade measure from the next Congress, Clay brought forward in 1833 a compromise measure for the gradual reduction of the tariff to a 20% ad valorem basis extending over a period of nine years. It lost Clay

the support of ardent protectionists but was hailed with favour by the people at large.

Clay's interest in internal improvements resulted naturally from his interest in western expansion and development. He supported the Federal financing or aiding of roads, canals and other schemes of transportation which would bind the east and west together. For a time he argued for the return to individual States of the receipts from all public lands sold within its borders.

BY COURTESY OF THE LEXINGTON CHAMBER OF COMMERCE
"ASHLAND," THE HOME OF HENRY CLAY IN LEXINGTON, KY.

This plan, together with many of his special projects, failed, but the general impetus of his oratory and argument was not lost.

Clay also interested himself passionately in the struggle of the South American nations for their independence. He made resounding speeches in the House in favour of the "eighteen millions of people struggling to burst their chains." He advocated an alliance in the two Americas to counterbalance the Holy Alliance of Europe and work against its designs. He was among the first to recommend recognition of the new nations by the United States, and consequently is still remembered with affection by them. Similarly, in 1824, he made an impassioned speech in favour of Greek independence and supported Webster's resolution for sending an agent or commissioner to that country.

But of all causes and questions, Clay's career was connected most intimately with that of slavery. When only 22 Clay had vainly urged an emancipation clause for the new constitution of Kentucky and never ceased to regret its failure. In 1820 he congratulated the new South American republics on having abolished slavery, pointing out that in this important point of progress they were in advance of the United States. The same year, however, threats of the Southern States to destroy the Union led him to advocate the "Missouri Compromise," which, while keeping slavery out of all of the rest of the territory included in the "Louisiana Purchase" north of Missouri's southern boundary, permitted it in that State. When the slave power became more aggressive in and after the year 1831, Clay defended the right of petition for the abolition of slavery in the District of Columbia, and opposed Calhoun's bill forbidding the use of the mails to "abolition" newspapers and documents. Though he favoured the freedom of the mails and press as regards slavery, he disliked the abolitionists and, because of their insistent, uncompromising demands, held them largely responsible for the hatred and strife which menaced the Union. Clay was lukewarm toward recognizing the independence of Texas lest it should aid the increase of slave territory. Yet he was so anxious to set himself right with the South that he prepared an elaborate speech for the purpose which received pro-slavery approval. His attitude resulted, as he himself declared, in the abolitionists denouncing him as slave-holder, and the slave-holder as an abolitionist. Such straddling undoubtedly was a prime factor in his loss of the presidency, which he always held in view. In 1844, for instance, while a candidate for the presidency, he announced himself against the annexation of Texas, but on other grounds than slavery. By not pronouncing definitely on the real issue he lost supporters from men of both pro-slavery and anti-slavery sentiments instead of winning them as he had hoped. His compromising spirit upon the question promised to bear fruit, however, when in the crisis of 1850 he was able to bring about the series of measures known collectively as the "Compromise of 1850." The situation was acute, the South was on the point of secession, statesmen were frantic, every way of alleviating

the deadlock seemed to have failed. Clay, who had retired from the Senate several years before, was now an old and physically frail man, but had himself re-elected to that body where he could put forth and defend his measures. His speech was one of the ablest of his career. Webster in a notable speech seconded the measures as a last resort. Calhoun still bitterly opposed. A deadlock resulted because of the opposition of President Taylor to the plan, and was only removed upon the latter's death, whereupon Fillmore, friendly to the compromise, succeeded to his place. The compromise admitted California as a free State, organized Utah and New Mexico as territories without reference to slavery, and enacted a more efficient fugitive slave law. It was a noble climax to Clay's great career, but it did not, as he hoped, permanently save the Union from bloodshed. Its success was in the fact that it postponed the Civil War until the North had the immense growing power of the West as its ally. Clay did not live to see its failure, but died in 1852 at the height of his fame and popularity.

In one respect, however, Clay's whole political career had been a bitter disappointment, at least to the man himself. The nation never rewarded him with the highest office in its power to bestow, and which he so deeply coveted. This was in spite of the fact that for a generation he was the acknowledged leader of his party. One reason was that during the whole period sectional feeling was so strong that no leader of any one section could be elected. Peace had to be secured by choosing lesser men as compromise candidates. Another reason was Clay's own compromising nature which always won him enemies in both camps. His name was used comparatively early in connection with the presidency. He had hoped to be offered the office of secretary of State under Monroe in 1817, for at that time this official was regarded as next in line for the succession. Clay was greatly disappointed and pursued a policy of obstruction to the administration until the events culminating in the Missouri Compromise again led him to co-operate with Monroe. In 1824 Clay was a candidate with W. H. Crawford, Andrew Jackson and John Quincy Adams for the presidency. Choice between the two highest, Jackson and Adams, went to the House where Clay controlled the deciding vote. Though Jackson represented the West and its interests, to choose him would have meant the denial of all chances for himself in the following campaign, for the country would not be likely to choose two western leaders in succession. Temperamentally Clay was also opposed to Adams, but after a long conference he gave out that he would support the latter. Soon afterwards he accepted an appointment as secretary of State, under Adams, and Jackson's supporters immediately charged a corrupt bargain between the two. Historians generally feel that Clay sincerely favoured Adams, but ever after Clay was kept busy explaining and denying the allegation of a bargain. It made Jackson his bitter enemy for life. John Randolph of Virginia pressed the accusation until Clay hotly consented to a duel to defend his honour. Neither was hurt. Clay's action so alienated his western supporters that it also must be ascribed as one of the reasons why he never achieved the presidency. In fact when he finished his term as secretary of State he had to go home "to mend his fences" in order to ensure his re-election to Congress. It proved the most difficult and most important campaign of his life, for, had he failed, it would have meant the eclipse of his political career.

By his enemies Clay's compromises were often ascribed to timidity or to hedging for political purposes. They can just as truly be represented as the acts of a man of great human understanding and sympathies, anxious to enter into the point of view of others. There is every indication that they represent a philosophical attitude toward life. "All legislation, all government, all society is founded upon the principle of mutual concession, politeness, comity, courtesy . . . I bow to you today because you bow to me." Such were his words and sentiments. The compromises represent his greatest political achievements. As "the great pacificator" he occupies a place in the memory of his countrymen.

When not in Washington Clay's home was on his estate at Ashland, Kentucky. He took a great interest in its practical man-

agement and especially devoted himself to the breeding of beautiful Kentucky horses. He was an excellent rider. Though Clay repeatedly denounced slavery as an evil, tradition and habit allowed him to keep slaves on his own plantation. He treated them considerately and they were devoted to him. When very young Clay married Lucretia Hart, a cousin of Thomas Hart Benton. Five sons and six daughters were born to them. But misfortune seemed to hang over the family. All of the daughters died before the father. One son was killed in the Mexican War, and another became insane after an accident. Clay's acquaintances and friends were selected from all classes and occupations. His popularity with the people was immense, and he believed in them. Yet like many democratic leaders, notably his great western rival, Andrew Jackson, Clay was often arbitrary, autocratic and possessed of an irrepressible desire to rule. His imagination frequently ran away with his understanding while his imperious temper and ardent combativeness hurried him into disadvantageous positions. Great crowds always met him wherever he was to speak because of his matchless voice and fascinating personality. In public he was of magnificent bearing, possessing the true oratorical temperament, the nervous exaltation that makes the orator feel and appear a superior being, transfusing his thought, passion and will into the mind and heart of the listener. In private he was an excellent conversationalist, possessing a fund of pleasant humour. His never-failing courtesy, his agreeable manners and a noble and generous heart for all who needed protection against the powerful or the lawless endeared him to hosts of friends.

BIBLIOGRAPHY.—See Calvin Colton, *The Works of Henry Clay* (1857; new ed., 1898), the first three volumes of which are an account of Clay's life and times; Carl Schurz, *Henry Clay* (1887); T. H. Clay, *Henry Clay* (1910); Gamaliel Bradford, "Henry Clay," in *Virginia Quarterly Review*, Jan. 1928. Much material will be found in the standard histories of the period and in Thomas H. Benton's *Thirty Years View* (1861). No complete and critical biography yet exists.

CLAY, commonly defined as a fine-grained, almost impalpable substance, very soft, more or less coherent when dry, retentive of water and often plastic when wet; it has an "earthy odour" when breathed upon or moistened (from O. Eng. *clæg*, a word common in various forms to Teutonic languages, cf. Ger. *Klei*). The chemical composition of clay varies according to the finely divided mineral matter present; usually the latter consists essentially of hydrous silicates of aluminium, iron, and alkalies. The constituent particles are commonly less than .005mm. in diameter and are often so small as to be colloidal. The upper limit of size in defining "clay" is taken by soil-analysts as .002mm. diameter, but by geologists often as much as .01mm. diameter. From the induration and alteration of clay are formed a number of rocks which collectively are known as "clay-rocks" or "pelitic rocks" (from Gr. *πηλός*, clay), e.g., mudstone, shale, slate. In nature clays are rarely free from foreign ingredients, some of which are visible to the eye, but others only by means of the microscope. The economic value of many clays is dependent on their freedom from (or occasionally the presence of) certain impurities. The commonest of these are (1) organic matter, humus (exemplified by clay-soils with an admixture of peat, oil-shales, carbonaceous shales); (2) fossils (such as plants in the shales of the Lias and Coal Measures, and shells in clayey deposits of all ages); (3) carbonate of lime (rarely altogether absent but abundant in marls, which may be defined as calcareous clays, cement-stones and argillaceous limestones); (4) sulphide of iron, as pyrite or marcasite, either finely diffused and giving the clay a blackish or dark-grey colour which "weathers" brown (e.g., London clay), or in nodules and concretions (e.g., Gault, Kimmeridge clay); (5) oxides of iron, which stain the clay to bluish, greenish and grey tints when in the ferrous state, and bright red, brown, or yellow when in the ferric condition, hence red and yellow ochres; (6) sand and silt, which are particles of coarser grain, frequently of detrital silica (thus forming loams, arenaceous clays, argillaceous sandstones, etc.).

The principal constituent minerals of clays are hydrated oxides of aluminium (bauxite) and iron (laterite), hydrated silicates of aluminium (such as kaolinite), finely-divided micas, chlorites and similar micaceous minerals. Recent work on French marine

clays of ages varying from Trias to Middle Tertiary has shown that the dominant mineral constituent is a hydrated silicate of aluminium magnesium, and potash, bravaisite, while kaolin is present in clays formed as residuals in fresh-water, or by pneumatolytic action.

A few of the most important clay rocks may be briefly described.

Brick and Tile Clays.—Almost any argillaceous material may be used for the manufacture of bricks and tiles. The colour and texture of the resulting products depend on the impurities in the clay, and also on the conditions of burning. The best materials for brick making contain a proportion of sandy and silty impurities (up to 30%) which prevent the clay showing too great a shrinkage on being fired. For tile making, less sandy material is desirable.

China-clay.—This is white, friable and earthy. It occurs as a result of decomposition of granite, porphyry and syenite, and occupies hollows or cavities, often of considerable depth. The crude material contains kaolinite (the pure hydrated silicate of aluminium), scaly white mica, quartz, tourmaline and other minerals. The kaolinite is produced by the action of heated gases which have escaped from the igneous rocks, on certain of the constituent minerals. Pure clay for commercial purposes is obtained by levigation of the crude product and repeated settlement in tanks.

Fire-clays.—These are those varieties which are refractory to heat. They are free from, or contain only small quantities of, alkalies and alkaline earths. They occur frequently in Carboniferous rocks, sometimes as under-clays of coal seams, or in association with lacustrine deposits of later age (e.g., inferior oolite of Yorkshire). In addition to hydrated aluminium silicates, some varieties contain free hydrated alumina, when they are known as bauxitic fire-clays (e.g., Ayrshire).

Boulder Clay.—This is formed by ice-action and consists usually of tough sandy clay, often unstratified, containing boulders of various sizes. The latter frequently display great variety in petrological character, are angular or rounded and sometimes marked with glacial striae.

Loess.—This is a fine calcareous clay deposited under the dry steppe or desert conditions which often followed the glaciation of a region. The loess occupies a world-wide fringing belt, lying beyond the margin of the glacial deposits, and in the main is regarded as formed of wind-borne material derived from the desiccated glacial clays.

Oil Shales.—While, as a result of drying and induration, clays which are homogeneous throughout yield *mudstones*, others split readily into leaflike plates or laminae parallel to their bedding and are termed *shales*. This laminated structure is accentuated by the presence of films of other substances such as sand, mica or vegetable debris. Shales occur frequently throughout the geological column, the most notable being those of the Carboniferous and Jurassic (e.g., Kimmeridge shales). Some of them contain much organic material in the form of globular, yellow, apparently resinous bodies, and when distilled yield paraffin oil, wax, compounds of ammonia, etc. In New South Wales, Scotland, Estonia, and parts of North America such oil-shales are worked on a commercial scale (see MINERAL OIL).

Cave-Earth (terra rossa).—This is a type of reddish clay found in limestone caves, which represents the insoluble and thoroughly weathered impurities left behind on solution of the calcareous matter. Similar residual clays occur on the surface or in hollows in limestone-country (see also CAVE DEPOSITS, and LATERITE).

For Red Clay, Green and Blue Muds, etc., see OCEANIC DEPOSITS. The article on SEDIMENTARY ROCKS should also be consulted.

(P. G. H. B.)

CLAY CROSS, an urban district, north-east Derbyshire, England, near the river Amber, on the L.M.S.R. and the Ashover light railway, $1\frac{1}{2}$ m. S. of Chesterfield. Pop. (1931) 8,493. Coal miners and foundry workers form the majority of the population.

CLAYMORE (from the Gaelic *claidheamh mòr*, "great sword"), the old two-edged broadsword with cross hilt, of which the guards were usually turned down, used by the Highlanders of

Scotland. The name is also wrongly applied to the single-edged basket-hilted sword adopted in the 16th century and still worn as the full-dress sword in the Highland regiments of the British army.

CLAYS, PAUL JEAN (1819–1900), Belgian marine painter, was born at Bruges in 1819, and died at Brussels in 1900. A Fleming in his feeling for colour, Clays set his palette with clean, strong hues, and their powerful harmonies were in striking contrast with the rusty, smoky tones then in favour. If he was not a "luminist" in the modern use of the word, he deserves at any rate to be classed with the founders of the modern naturalistic school. Among his works are: "Dutch Boats in the Flushing Roads," in the National Gallery, London; "The Port of Antwerp," "Coast near Ostend," and a "Calm on the Scheldt," in the Brussels gallery; "The Meuse at Dordrecht" in the Antwerp museum; "The Open North Sea," in the Pinakothek at Munich; and "The Festival of the Freedom of the Scheldt at Antwerp in 1863," in the Metropolitan Museum of Fine Arts, New York.

See Camille Lemonnier, *Histoire des Beaux-Arts* (Brussels, 1887).

CLAYTON, JOHN MIDDLETON (1796–1856), American politician, was born in Dagsborough, Del., on July 24, 1796. He came of an old Quaker family long prominent in the political history of Delaware. He graduated at Yale in 1815, and in 1819 began to practise law at Dover, Delaware. Engaging in politics, he became in 1824 a member of the state house of representatives, and in 1826–28 was secretary of state for Delaware. In 1829 he was elected to the U.S. Senate by the anti-Jackson forces, and in 1835 was re-elected as a Whig, but resigned in 1836. In 1845 he again entered the Senate, where he opposed the annexation of Texas and the Mexican War. In March, 1849, he became secretary of state in President Taylor's cabinet. His brief tenure of the state portfolio, which terminated July 22, 1850, soon after Taylor's death, was notable chiefly for the negotiation with the British minister, Sir Henry Lytton Bulwer of the Clayton-Bulwer Treaty (*q.v.*). He was once more a member of the Senate from March, 1853, until his death at Dover, Del., Nov. 9, 1856. By his contemporaries Clayton was considered one of the ablest debaters and orators in the Senate.

See the memoir by Joseph P. Comegys in the *Papers* of the Historical Society of Delaware, No. 4 (Wilmington, 1882).

CLAYTON-BULWER TREATY, a famous treaty between the United States and Great Britain, negotiated in 1850 by John M. Clayton and Sir Henry Lytton Bulwer (Lord Dalling) in consequence of the situation created by the project of an inter-oceanic canal across Nicaragua, each signatory being jealous of the activities of the other in Central America. Great Britain had large and indefinite territorial claims in three regions—Belize or British Honduras, the Mosquito Coast and the Bay islands. On the other hand, the United States, without territorial claims, held in reserve, ready for ratification, treaties with Nicaragua and Honduras, which gave her a certain diplomatic vantage with which to balance the *de facto* dominion of Great Britain.

The treaty bound both parties not to "obtain or maintain" any exclusive control of the proposed canal, or unequal advantage in its use. It guaranteed the neutralization of such canal. It declared that, the intention of the signatories being not only the accomplishment of "a particular object"—*i.e.*, that the canal, then supposedly near realization, should be neutral and equally free to the two contracting powers—"but also to establish a general principle," they agreed "to extend their protection by treaty stipulation to any other practicable communications, whether by canal or railway, across the isthmus which connects North and South America." Finally, it stipulated that neither signatory would ever "occupy, or fortify, or colonize, or assume or exercise any dominion over Nicaragua, Costa Rica, the Mosquito Coast or any part of Central America," nor make use of any protectorate or alliance, present or future, to such ends.

The treaty was signed on April 19, and was ratified by both Governments; but before the exchange of ratifications Lord Palmerston, on June 8, directed Sir H. Bulwer to make a "declaration" that the British Government did not understand the treaty "as applying to Her Majesty's settlement at Honduras, or its de-

pendencies." J. M. Clayton made a counter-declaration, which recited that the United States did not regard the treaty as applying to "the British settlement in Honduras commonly called British-Honduras . . . nor the small islands in the neighbourhood of that settlement which may be known as its dependencies"; that the treaty's engagements did apply to all the Central American States, "with their just limits and proper dependencies"; and that these declarations, not being submitted to the United States Senate, could of course not affect the legal import of the treaty. The interpretation of the declarations soon became a matter of contention. The phraseology reflects the effort made by the United States to render impossible a physical control of the canal by Great Britain through the territory held by her at its mouth—the United States losing the above-mentioned treaty advantages—just as the explicit abnegations of the treaty rendered impossible such control politically by either power. But Great Britain claimed that the excepted "settlement" at Honduras was the "Belize" covered by the extreme British claim; that the Bay islands were a dependency of Belize; and that, as for the Mosquito Coast, the abnegatory clauses being wholly prospective in intent, she was not required to abandon her protectorate. The United States contended that the Bay islands were not the "dependencies" of Belize, these being the small neighbouring islands mentioned in the same treaties; that the excepted "settlement" was the British-Honduras of definite extent and narrow purpose recognized in British treaties with Spain; that she had not confirmed by recognition the large, indefinite and offensive claims whose dangers the treaty was primarily designed to lessen; and that, as to the Mosquito Coast, the treaty was retrospective, and that the clause binding both not to "occupy" any part of Central America or the Mosquito Coast necessitated the abandonment of such territory as Great Britain was already actually occupying or exercising dominion over, and the complete abandonment of the British protectorate over the Mosquito Indians. It seems to be a just conclusion that when in 1852 the Bay islands were erected into a British "colony" this was a flagrant infraction of the treaty; that as regards Belize the American arguments were decidedly stronger, and more correct historically; and that as regards the Mosquito question, inasmuch as a protectorate seems certainly to have been recognized by the treaty, to demand its absolute abandonment was unwarranted, although to satisfy the treaty Great Britain was bound materially to weaken it.

In 1859–60, by British treaties with Central American States, the Bay islands and Mosquito questions were settled nearly in accord with the American contentions. But by the same treaties Belize was accorded limits much greater than those contended for by the United States. This settlement the latter power accepted without cavil for many years.

In 1880–84 a variety of reasons were advanced why the United States might justly repudiate at will the Clayton-Bulwer Treaty. The arguments advanced were quite indefensible in law and history, and although the position of the United States in 1850–60 was in general the stronger, that of Great Britain was even more conspicuously strong in the years 1880–84. In 1885 the former Government reverted to its traditional policy, and the Hay-Pauncefote Treaty of 1902, which replaced the Clayton-Bulwer Treaty, adopted the rule of neutralization for the Panama Canal.

Latané, *Diplomatic Relations of the United States and Spanish America* (Baltimore, 1900); T. J. Lawrence, *Disputed Questions of Modern International Law* (2nd ed., Cambridge, England, 1885); Sir E. L. Bulwer in 99 *Quarterly Rev.* 235–286, and Sir H. Bulwer in 104 *Edinburgh Rev.* 280–298.

CLAY-WITH-FLINTS, in geology, a name given to a deposit of stiff red, brown or yellow clay, containing many flints, whole or broken, with some round pebbles of hard rock. It covers large areas in south-eastern and southern England, usually lying on chalk. It is commonly considered to represent the insoluble residue of the chalk left by weathering (mainly solution), but may include deposits formed in other ways, of which the following have been suggested: (a) that it is the residue of patches of Tertiary strata which once extended more widely over the chalk

than at present. This is favoured by the presence of pebbles other than flint: (b) that it may be a glacial deposit, in fact, a boulder-clay, indicating an extension of the ice-sheet somewhat further than is usually believed. (See GLACIAL PERIOD.) These questions must be regarded as still undecided, but there can be little doubt that the insoluble residue theory is applicable over wide areas.

(R. H. RA.)

CLAZOMENAE, an ancient town of Ionia and a member of the Ionian Dodecapolis (Confederation of Twelve Cities), on the Gulf of Smyrna, about 20 m. W. of that city. Though not in existence before the arrival of the Ionians in Asia, its original founders were largely settlers from Phlius and Cleonae. It stood originally on the isthmus connecting the mainland with the peninsula on which Erythrae stood; but the inhabitants, alarmed by the encroachments of the Persians, removed to one of the small islands of the bay, and there established their city. This island was connected with the mainland by Alexander the Great by means of a pier, the remains of which are still visible. During the 5th century it was for some time subject to the Athenians, but about the middle of the Peloponnesian war (412 B.C.) it revolted. After a brief resistance, however, it again acknowledged the Athenian supremacy, and repelled a Lacedaemonian attack. Under the Romans Clazomenae was included in the province of Asia, and enjoyed immunity from taxation. It was the birthplace of the philosopher Anaxagoras. It is famous for its painted terracotta sarcophagi, which are the finest monuments of Ionian painting in the 6th century B.C.

(E. GR.)

CLEANING: see DRY CLEANING.

CLEANTHES (c. 301–232 or 252 B.C.), Stoic philosopher, was born at Assos in the Troad. He came to Athens, where he listened first to the lectures of Crates the Cynic, and then to those of Zeno the Stoic, supporting himself meanwhile by working all night as water-carrier to a gardener (hence his nickname *φρεάντης*). On the death of Zeno in 263, he became the leader of the school. Among his pupils were his successor, Chrysippus, and Antigonus, king of Macedon.

Cleanthes produced very little that was original, though he wrote some 50 works, of which fragments have come down to us. The principal is the large portion of the *Hymn to Zeus*, which has been preserved in Stobaeus. He regarded the sun as the abode of God, the intelligent providence, or (in accordance with Stoic materialism) the vivifying fire or aether of the universe. Virtue, he taught, is life according to nature; but pleasure is not according to nature. The principal fragments of Cleanthes' works are contained in Diogenes Laertius and Stobaeus; some may be found in Cicero and Seneca.

See G. C. Mohinke, *Kleanthes der Stoiker* (Greifswald, 1814); C. Wachsmuth, *Commentationes de Zenone Citienisi et Cleanthe Assio* (Göttingen, 1874–75); A. C. Pearson, *Fragments of Zeno and Cleanthes* (1891); art. by E. Wellmann in Ersch and Gruber's *Allgemeine Encyclopädie*; R. Hürzel, *Untersuchungen zu Ciceros philosophischen Schriften*, ii. (1882), containing a vindication of the originality of Cleanthes; *Hymn of Cleanthes*, tr. E. H. Blakeney, "Texts for Students" series, vol. xxvi. (1921); A. B. Kirsche, *Forschungen auf dem Gebiete der alten Philosophie* (1840); also works quoted under STOICS.

CLEARCHUS, the son of Rhamphias, a Spartan general and condottiere. Born about the middle of the 5th century B.C., Clearchus was sent with a fleet to the Hellespont in 411 and became harmost of Byzantium. His severity, however, made him unpopular, and in his absence the gates were opened to the Athenians under Alcibiades (409). Subsequently appointed by the ephors to settle the affairs of Byzantium and to protect it from Thracian attacks, he made himself tyrant, and, when driven thence by a Spartan force, fled to Cyrus (q.v.). In the "expedition of the ten thousand," Clearchus led the Peloponnesians. On Cyrus's death Clearchus conducted the retreat, until, being treacherously seized with his fellow-generals by Tissaphernes, he was handed over to Artaxerxes and executed (Thuc. viii. 8, 39, 80; Xen., *Hellenica*, i. 3, 15–19; *Anabasis*, i. ii.; Diodorus xiv. 12, 19–26). Clearchus was a typical Spartan, an able and energetic soldier, but lacking refinement and humanity.

CLEARFIELD, a borough of Clearfield county, Pennsylvania, U.S.A., 35m. N. of Altoona, on the west branch of the Susque-

hanna river, at an altitude of 1,108ft., in the "Central Pennsylvania" coal-field. It is on Federal highway 322; is served by the Buffalo, Rochester and Pittsburgh, the New York Central and the Pennsylvania railways; and has an air-port lighted by beacons. The population in 1920 was 8,529; 1930 it was 9,221. It is the county seat, a wholesale distributing centre, and has various manufacturing industries, especially large fire-brick, tile and sewer-pipe works, using the fire-clay that abounds in the vicinity, a large nickel rolling-mill and tanneries. Clearfield was so named because the first white settlers found it already cleared of timber. In 1805 it was chosen as the site for the county seat.

CLEARING HOUSE. When business houses or firms engaged in the same kind of activity have large dealings with each other it is an obvious convenience and economy to establish a mutual institution to enable them to set off their transactions with each other and to clear them, thus making it necessary to pay to each other at agreed times only such balances of account as are revealed by the clearance. Such institutions are called clearing houses, and they have been established in all great commercial nations for many branches of industry. The chief of them are Bankers' Clearing Houses (q.v.) and Railway Clearing Houses, which are described under RAILWAYS.

The London Stock Exchange Clearing House deals with transactions in stock, the clearing being effected by balance-sheets and tickets; the balance of stock to be received or delivered is shown on a balance-sheet sent in by each member, and the items are then cancelled against one another and tickets issued for the balances outstanding. The New York Stock Exchange Clearing House does similar work. The settlements on the Paris Bourse are cleared within the Bourse itself, through the Compagnie des Agents de Change de Paris.

For details concerning clearing house operations in the United States see Theodore Gilman, *A Graded Banking System Formed by the Incorporation of Clearing Houses under a Federal Law* (Boston, 1898); Jerome Thralls, *The Clearing House* (1916); Harvey White Magee, *A Treatise on the Law of National and State Banks, Including the Clearing House* (Albany, N.Y., 1921); and Walter Eaton Spahr, *The Clearing and Collection of Checks* (1926).

CLEARWATER, a city on the west coast of Florida, U.S.A., 30m. W. of Tampa; the county seat of beautiful Pinellas county, which occupies a small peninsula between the Gulf of Mexico and Clearwater bay. It is served by the Atlantic Coast Line and the Seaboard Air Line railways. In 1900 the population was 343; in 1925 (State census) 5,004 (39% negroes); and in 1930, after annexations of territory bringing the area to 175sq.m., it was 7,607 (Federal census). Clearwater is in a citrus-fruit and market-gardening region, has fisheries of importance, and is a winter resort. A commission-manager form of government was adopted in 1923.

CLEAT, a wedge-shaped piece of wood fastened to ships' masts and elsewhere, to prevent a rope, collar or the like from slipping, or to act as a step; more particularly a piece of wood or metal with double or single horns used for belaying ropes. A "cleat" is also a wedge fastened to a ship's side to catch the shores in a launching cradle or dry dock. "Cleat" is also used in mining for the vertical cleavage-planes of coal. The word is common in various forms to many Teutonic languages, in the sense of a wedge or lump, cf. "clod" and "clot."

CLEATOR MOOR, an urban district, west Cumberland, England, 4½ m. S.E. of Whitehaven, served by the L.M.S.R. Pop. (1931) 6,582. The town lies between the valleys of the Ehen and its tributary the Dub Beck, in a district rich in coal and iron ore. The mines together with metal works employ almost the entire population.

CLEAVERS or **GOOSE-GRASS**, *Galium Aparine* (family Rubiaceae), a common plant in hedges and waste places, with a long, weak, straggling, four-sided, green stem, bearing whorls of six to eight narrow leaves, ½ to 2in. long, and, like the angles of the stem, rough from the presence of short, stiff, downward-pointing, hooked hairs. The small, white, regular flowers are borne, a few together, in axillary clusters, and are followed by the large, hispid, two-celled fruit, which, like the rest of the plant, readily

clings to a rough surface, whence the common name. The plant has a wide distribution throughout the north temperate zone, and is also found in temperate South America.

CLEBSCH, ALFRED (1833-1872), German mathematician, was born at Königsberg, Prussia, on Jan. 19, 1833. He was educated at Königsberg, and in 1858 was appointed to the chair of theoretical mechanics at Karlsruhe Polytechnic. In 1863 Clebsch went to the University of Giessen and in 1868 to Göttingen, where he remained until his death. His attention was turned to algebra and geometry after a study of Salmon's works. Clebsch worked at mathematical physics, the calculus of variation, partial differential equations of the first order, the general theory of curves; he applied Abelian functions to geometry and made use of determinants. In 1867 Clebsch, in conjunction with Carl Neumann, founded the *Mathematische Annalen*. He died of diphtheria on Nov. 7, 1872. Clebsch was the author of *Vorlesungen über Geometrie*, which was edited by Ferdinand Lindemann of Munich in 1875, and of *Theorie d. Elasticität fester Körper* (1862), which was translated into French by Saint-Venant.

CLEBURNE, a city of Texas, U.S.A., 25m. S. of Ft. Worth; the county seat of Johnson county. It is served by the Santa Fe and the Trinity and Brazos Valley railways. The population was 12,820 in 1920 (88% native white) and was 11,539 in 1930 by the Federal census. The raising of cotton and grain and the rearing of live stock are the leading industries in the vicinity. Among the city's industries are cotton gins and compresses; cotton-seed oil, cabinet, broom, mattress and sash factories; also, there are railroad shops employing 1,000 men. Cleburne was settled about 1867; incorporated in 1871; and was named after Patrick Ronayne Cleburne (1828-1864), a major general of the Confederate army, who was called "the Stonewall of the West."

CLECKHEATON, a parish, West Riding of Yorkshire, England, 5½ m. S.E. of Bradford, on the L.M.S.R. Pop. (1921) 12,537. The industries comprise the manufacture of woollens, blankets, flannel, wire-card and machinery. Cleckheaton parish is in the Spenborough urban district, pop. (1931) 30,962.

CLEETHORPES, a town and watering-place in Lincolnshire, England; 2¼m. S.E. of Great Grimsby by a branch of the L.N.E.R. Pop. of urban district (1931) 28,624. Cleethorpes faces eastward to the North sea, but its shore of fine sand, affording good bathing, actually belongs to the estuary of the Humber. The sea-wall forms a pleasant promenade. The suburb of New Clew connects Cleethorpes with Grimsby. The church of the Holy Trinity and St. Mary is principally Norman of various dates, but pre-Conquest work appears in the tower. Cleethorpes is greatly favoured as a health resort by people from the midland countries, Lancashire and Yorkshire.

CLEF, in musical notation, is a sign used to indicate the position and pitch of the various notes represented on the stave.

Three such signs are now in use,  (or ) ,  and , of

which  stands for the note *c'*, otherwise middle C on the piano-

forte,  for the F below and  for the G above. Hence when

one of these notes is thus indicated, e.g.,  or , a key,

or clef, is thereby provided from which all the others can be reckoned. A representation of the Great Stave of eleven lines, showing the position on it occupied by each clef sign, will make the matter clear.

From this it will be seen that the F (bass) and G (treble or violin) clefs are the lower and upper five lines respectively and

that the C clef (variously known as the tenor or alto clef, according to the particular line on which it is placed) consists of five lines taken from the middle; for it should be explained further that "clef" signifies not only the individual sign but also the group of lines on which it stands, although strictly speaking "stave" is here the more accurate term.

In pianoforte, vocal and most other scores, only the F and G clefs are nowadays used, but the C clef is still retained for the viola and one or two other instruments, the choice of the particular clef used being governed, as it will be understood, by the pitch and compass of the instrument written for, the object aimed at being to include as much of the music as possible within the limits of a five-line stave. It will also be understood that in practice the middle line of the Great Stave is normally omitted, a short additional line known as a leger (or ledger) line being employed to take its place when the intermediate C is required—

It may be noted further that the clef signs as we now know them are simply much modified and conventionalized forms of the letters of the three notes which they stand for—F, C and G. (See MUSICAL NOTATION.)

CLEFT PALATE and **HARE-LIP**, in surgery. Cleft palate is a congenital cleavage in the roof of the mouth, and is frequently associated with hare-lip. Both conditions are due to faulty development and may be hereditary. The infant is prevented from sucking, and an operation is necessary. The most favourable time for operating is between the age of two weeks and three months, and if the cleft is closed at this early date, not only are the nutrition and general development of the child greatly improved, but the voice is probably saved from much of the unpleasant tone associated with a defective roof to the mouth. After the cleft in the palate has been effectually dealt with, the hare-lip can be repaired with ease and success.

Hare-lip.—In the hare the splitting of the lip is in the middle line, but in the human subject for developmental reasons it is on one or on both sides of the middle line. Though we are unable to explain why development should miss the mark in formation of the lip and palate, it is unlikely that maternal impressions have anything to do with it. As a rule, the supposed "fright" comes long after the ninth week of foetal life when the lips are developed. The best time for operating on a hare-lip depends upon circumstances, in a favourable case within the first few days of birth.

CLEISTHENES, the name of two Greek statesmen, (1) of Athens, (2) of Sicyon, of whom the first is far the more important.

(1) **CLEISTHENES**, the Athenian statesman, was the son of Megacles, the Alcmaeonid, and Agariste, daughter of Cleisthenes of Sicyon. The Alcmaeonidae had been in exile during the Peisistratid tyranny but gained the favour of Delphi by their munificence in the rebuilding of the temple, and their reinstatement was imposed by the oracle upon the Spartan king, Cleomenes (q.v.). Aristotle's *Constitution of Athens* treats the alliance of the Peisistratids with Argos, the rival of Sparta in the Peloponnese, as the chief ground for the action of Cleomenes who expelled Hippias in 511-510 B.C., leaving Athens once again at the mercy of the powerful families.

Cleisthenes, on his return, realized that Athens would not tolerate a new tyranny, nor were the other nobles willing to accept him as leader of an oligarchy. It was left for him to "take the people into partnership" as Peisistratus had in a different way done before him. Solon's reforms had failed, primarily because they left unimpaired the power of the great landed nobles. This evil of local influence Peisistratus had concealed by satisfying the nominally sovereign people that in him they had a sufficient representative. It was left to Cleisthenes to adopt the remedy of giving substance to the form of the Solonian constitution. His first attempts roused the aristocrats to a last effort; Isagoras appealed to the

Spartans to come to his aid. Cleisthenes retired on the arrival of a herald from Cleomenes, reviving the old question of the curse. The democrats, however, rose, and after besieging Cleomenes and Isagoras in the Acropolis, let them go under a safe-conduct, and brought back the exiles. We are not told when and how the ascendancy of Cleisthenes came to an end. It is stated that Cleisthenes, hard pressed in the war with Boeotia, Euboea and Sparta (Herod. v. 73), sent ambassadors to ask the help of Persia. Associated as he was with the democrats, the Peisistratid party, this is not improbable. The existence of a strong philo-medic party is clear from the story of the shield after the battle of Marathon, for which the Alcmaeonidae were blamed. (See G. B. Grundy, *Great Persian War*, ch. iv.) The gift and withdrawal of Athenian help in the Ionian War (498) is another indication of division of opinion in Athens. Aelian says that he was a victim to his own device of ostracism (*q.v.*); this may perhaps indicate that his political career ended in disgrace, a hypothesis which is explicable on the ground of this attempted Persian alliance.

Cleisthenes realized that the dead-weight which held the democracy down was the influence on politics of the clan unit with its religious associations. Therefore his prime object was to dissociate the clans and the phratries from politics, and to give the democracy a new electoral basis in which old associations and vested interests would become ineffective. His first step was to abolish the four Solonian tribes and create ten new ones. Each of the new tribes was subdivided into "demes" (roughly "townships"); this organization did not, except politically, supersede the system of clans and phratries whose old religious signification remained untouched. The new tribes, however, did not represent local interests. Further, the tribe names were taken from legendary heroes, and, therefore, contributed to the idea of a national unity; even Ajax, the eponym of the tribe Aeantis, though not really Attic, was famous as an ally. (Herod. v. 66) and had been adopted as a national hero. Each tribe had its shrine and its particular hero-cult, which, however, was free from local association and the dominance of particular families. This national idea Cleisthenes further emphasized by setting up in the market-place at Athens a statue of each tribal hero.

The next step was the organization of the deme. Within each tribe he grouped demes (see below), each of which had its census-list kept by the demarch (local governor), who was elected popularly and held office for one year and presided over meetings affecting local administration and the provision of crews for the state-navy. According to the Aristotelian *Constitution of Athens*, Cleisthenes further divided Attica into three districts, Urban and Suburban, Inland (*Mesogaios*) and Maritime (*Paralia*), each of which was subdivided into ten *trittyes*; each tribe was composed of three trittyes, one in each of the three districts. The demes were arranged in ten groups but the number of demes in a tribe was not uniform. The trittyes might consist of one or several demes and the number of members of a deme varied greatly, though, at first, the division was local, *i.e.*, a deme consisted of its residents, the qualification became hereditary, a man belonging to his father's deme wherever he lived. Hence the distinction between resident demesmen and residents belonging to another deme (*ἐγκλητήριον*). The main purpose of the reform was to do away with the religious qualification of connection with clan or phratry and so facilitate the enfranchisement of new citizens. The artificial arrangement of the trittyes was intended to weaken the authority of the Eupatrid families in the tribes whose widely separated trittyes could not easily be brought under influence.

It has been asked whether we are to believe that Cleisthenes invented the demes. To this the answer is in the negative. The demes were undoubtedly primitive divisions of Attica. The most logical conclusion perhaps is that Cleisthenes, while he did create the demes which Athens itself comprised, did not create the country demes, but merely gave them definition as political divisions. Thus the city itself had six demes in five different tribes, and the other five tribes were represented in the suburbs and the Peiraeus. In the Cleisthenean system there was one great source of danger, namely that the residents in and about Athens must always have had more weight in elections than those in distant demes.

Moreover a special class, the new commercial element in the citizenship devised by Solon and fostered by Cleisthenes, soon came to have a preponderating influence in the city and suburbs.

A second problem is the franchise reform of Cleisthenes. Aristotle in the *Politics* (iii. 2.3 = 1275 b) says that Cleisthenes created new citizens by enrolling in the tribes "many resident aliens and emancipated slaves." But the Aristotelian *Constitution of Athens* asserts that he gave "citizenship to the masses." *Μέροισι* had been encouraged to settle in Athens by Solon and the grant of citizenship had been made to many skilled in trades and handicrafts. The Peisistratids, like the Etruscan dynasty at Rome, naturally favoured this commercial "plebs" as a support against the aristocrats. After their expulsion a revision of the citizen-roll had removed many or all of these as *γένημ' ἀκαθαροί*. Cleisthenes restored these and opened the way to citizenship to all satisfactory resident aliens, so strengthening the position of the democracy.

The Boulē (*q.v.*) was reorganized to suit the new tribal arrangement, and was known henceforward as the Council of the Five Hundred, fifty from each tribe, each fifty acting as an executive committee (*πρυτάνεις* [*q.v.*]) for one month. The system of ten tribes led in course of time to the construction of boards of ten to deal with military and civil affairs, *e.g.* the Strategi (see STRATEGUS), the *Apodektai*, and others. Of these the former cannot be attributed to Cleisthenes, but on the evidence of Androtion it was Cleisthenes who replaced the *Kolakretai*, by the *Apodektai* ("receivers"), who were controllers and auditors of the finance department. *Kolakretai* were very ancient Athenian magistrates; they were again important in the time of Aristophanes (*Wasps*, 693, 724; *Birds*, 1541), and presided over the payment of the dicasts instituted by Pericles. The *Kolakretai* remained in authority over the internal expenses of the Prytaneum. A further change which followed from the new tribal system was the reconstitution of the army; this, however, probably took place about 501 B.C., and cannot be attributed directly to Cleisthenes. It has been said that the deme became the local political unit, replacing the naucrarchy (*q.v.*). But the naucrarchies still supplied the fleet, and were increased in number from forty-eight to fifty.

The device of ostracism is the final stone in the Cleisthenean structure. An admirable scheme in theory, and, at first, in practice, it deteriorated in the 5th century into a mere party weapon.

(2) CLEISTHENES OF SICYON (*c.* 600–570), grandfather of the above, became tyrant of Sicyon as the representative of the conquered Ionian section of the inhabitants. He emphasized the destruction of Dorian predominance by giving ridiculous epithets to their tribal units, which from Hylleis, Dymanes and Pamphyli became Hyatae ("Swine-men"), Choireatae ("Pig-men") and Oneatae ("Ass-men"). He also attacked Dorian Argos, and suppressed the Homeric "rhapsodists" who sang the exploits of Dorian heroes. He championed the cause of the Delphic oracle against the town of Crisa in the Sacred War (*c.* 590). Crisa was destroyed, and Delphi became one of the meeting-places of the Delphic amphictyony (see AMPHICTYONY). The Pythian games were re-established with new magnificence, and Cleisthenes won the first chariot race in 582. He founded Pythian games at Sicyon, and built a new Sicyonian treasury at Delphi. His power was so great that when he offered his daughter Agariste in marriage, some of the most prominent Greeks sought the honour, which fell upon Megacles, the Alcmaeonid. The story of the rival wooers with the famous retort, "Hippocleides don't care," is told in Herod. vi. 125; see also Herod. v. 67 and Thuc. i. 18.

CLEISTHENES is also the name of an Athenian pilloried by Aristophanes (*Clouds*, 354; *Thesm.* 574) as a fop and a profligate.

CLEITARCHUS, one of the historians of Alexander the Great, possibly a native of Egypt, or at least spent some time at

the court of Ptolemy Lagus. Quintilian (*Instit.* x. i. 74) credits him with more ability than trustworthiness, and Cicero (*Brutus*, ii.) accuses him of giving a fictitious account of the death of Themistocles. But his history was popular, and much used by Diodorus Siculus, Quintus Curtius, Justin and Plutarch.

The fragments, some thirty in number, chiefly preserved in Aelian and Strabo, will be found in C. Müller's *Scriptores Rerum Alexandri Magni* (in the Didot *Arrian*, 1846); monographs by C. Raun, *De Clitarcho Diodori, Curtii, Justinii auctore* (1868), and F. Reuss, "Hellenistische Beiträge" in *Rhein. Mus.* lxiii. (1908), pp. 58-78.

CLEITHRAL, an architectural term applied to a Greek temple whose roof completely covered it; in contradistinction to hypaethral, applied to one partly or wholly open to the sky.

CLEITOMACHUS, Greek philosopher, was a Carthaginian, who came to Athens about the middle of the 2nd century B.C. at the age of 24. He studied principally under Carneades, whose views he adopted and propagated and whom he succeeded as chief of the New Academy in 129 B.C. Of Cleitomachus' works we possess scarcely anything but a few titles, among which are *Περὶ ἐποχῆς* (on suspension of judgment) and *Περὶ αἰδέσεων* (about philosophical sects). Cicero highly commends his works and admits his own debt in the *Academics* to the treatise *Περὶ ἐποχῆς*. Parts of Cicero's *De Natura* and *De Divinatione*, and the treatise *De Fato* are also in the main based upon Cleitomachus.

See E. Wellmann in Ersch and Gruber's *Allgemeine Encyclopädie*; R. Hirzel, *Untersuchungen zu Ciceros philosophischen Schriften*, i. (1877); Diog. Laërt. iv. 67-92; Cicero, *Acad. Pr.* ii. 31, 32, and *Tusc.* iii. 22.

CLEITOR or **CLITOR**, a town of ancient Greece, stood in a fertile plain of Arcadia to the south of Mt. Chelmos, not far from a stream of its own name. In the neighbourhood was a fountain, the waters of which were said to deprive those who drank them of the taste for wine. The town was of considerable local importance and its inhabitants combined love of liberty with dominion over neighbours. It fought against Orchomenus in the Theban war and joined the other Arcadian cities in the foundation of Megalopolis. As a member of the Achaean League it was on several occasions the seat of the federal assemblies, and was besieged by the Aetolians in 220 B.C. It coined money till the time of Septimius Severus. Its ruins at Paleopoli are about 3 m. from a village that preserves the ancient name. The greater part of the walls with several semi-circular towers can be clearly made out; also three Doric temples and a small theatre.

CLELAND, WILLIAM (1661?-1689), Scottish Covenanting poet and soldier, son of a gamekeeper, was probably brought up on the marquess of Douglas's estate in Lanarkshire, and was educated at St. Andrews university. He joined the army of the Covenanters, was present at Drumclog and fought at Bothwell Bridge. He escaped to Holland, but in 1685 was again in Scotland at the time of the abortive invasion of the earl of Argyll. He escaped once more, to return in 1688 as agent for William of Orange. He was appointed lieutenant-colonel of the Cameronian regiment entrusted with the defence of Dunkeld, which they held against the fierce assault of the Highlanders on Aug. 26. This repulse of the Highlanders ended the Jacobite rising, but Cleland fell in the struggle. He wrote *A Collection of Several Poems and Verses* composed upon various occasions (published posthumously, 1697).

See *An Exact Narrative of the Conflict of Dunkeld . . . collected from several officers of the regiment* (1689).

CLEMATIS, in botany a genus of the crowfoot family (Ranunculaceae), containing 220 species and widely distributed. It is represented in England by *Clematis vitalba*, old man's beard or traveller's joy, a common plant on chalky or light soil. The plants are shrubby climbers with generally compound, opposite leaves, the stalk of which is sensitive to contact like a tendril, becoming twisted round suitable objects and thereby giving support to the plant. The flowers are arranged in axillary or terminal clusters; they have no petals, but white or coloured, often large sepals, and an indefinite number of stamens and carpels. They contain no honey, and are visited by insects for the pollen, which is plentiful. The fruit is a head of achenes, each bearing the long-bearded, persistent style, suggesting the popular name. This

feathery style is an important agent in the distribution of the seed by means of the wind.

Inclusive of the sections *Viorna* and *Atragene*, which some botanists regard as separate genera, there are some 30 species of *Clematis* native to North America. Of these, the following representatives are more or less cultivated: the Virginia virgin's bower (*C. virginiana*), found from Nova Scotia to Manitoba and south-

WILD CLEMATIS, OR TRAVELLER'S JOY, A CLIMBING PLANT SOMETIMES CULTIVATED TO ADORN GARDEN TRELLISES. THE FEATHERY STYLES OF THE FRUITS (ACHENES) FACILITATE DISPERSAL OF SEED BY THE WIND

ward to Georgia and Tennessee; the western virgin's bower (*C. ligusticifolia*), growing from North Dakota and Missouri westward to British Columbia and California; the purple virgin's bower (*C. verticillaris*), found from Hudson bay to Minnesota and south-eastward to Connecticut and Virginia; the scarlet virgin's bower (*C. texensis*), native to Texas; and the pipe-stem virgin's bower (*C. lasiantha*), of California and Oregon.

Several of the species, especially the large-flowered ones, are favourite garden plants, well adapted for covering trellises or walls, or trailing over the ground. Many garden forms have been produced by hybridization; among the best known is *C. Jackmanni*.

See T. Moore and G. Jackman, *The Clematis as a Garden Flower*; G. Nicholson, *Dictionary of Gardening*, i. (1885) and *Supplements*.

CLEMENCEAU, GEORGES (1841-1929), French statesman, was born at Mouilleron-en-Pareds, Vendée, on Sept. 28, 1841. He adopted medicine as his profession. Interested in the progressive ideas of John Stuart Mill, he decided to investigate for himself the results of the application to affairs of democratic theory. He therefore embarked for the United States, taking with him Mill's *Auguste Comte and Positivism* to translate into French. He arrived in New York early in 1866 and remained there or in New England for three years, writing descriptions of American post-war conditions to the Paris *Temps* and teaching French in a girls' school at Stamford, Conn. In this way he passed

what he characterized as the three happiest years of his life. In 1869 he returned to Paris and after the revolution of 1870 he was nominated mayor of the 18th arrondissement of Paris (Montmartre). On Feb. 8, 1871, he was elected as a Radical to the National Assembly for the department of the Seine, and voted against the peace preliminaries. The execution of Generals Lecomte and Clément Thomas by their mutinous soldiers on March 18, which he vainly tried to prevent, brought him into collision with the central committee of the National Guard, and they ordered his arrest, but he escaped; he was accused, however, by various witnesses, at the subsequent trial (Nov. 29), of not having intervened when he might have done, and though he was cleared of this charge it led to a duel, for his share in which he was prosecuted and sentenced to a fine and a fortnight's imprisonment.

Meanwhile, on March 20, 1871, he had introduced in the National Assembly at Versailles, on behalf of his Radical colleagues, the bill establishing a Paris municipal council of 80 members; but he was not returned himself at the elections. He tried with the other Paris mayors to mediate between Versailles and the hôtel de ville, but failed, and accordingly resigned his mayoralty and his seat in the assembly, and temporarily gave up politics; but he was elected to the Paris municipal council on July 23, 1871, for the Clignancourt *quartier*, and retained his seat till 1876, passing through the offices of secretary and vice-president, and becoming president in 1875. In 1876 he stood again for the Chamber of Deputies, and was elected for the 18th arrondissement. He joined the extreme Left, and his energy and mordant eloquence speedily made him the leader of the Radical section. In 1877, after the *Seize mai* (see FRANCE: History), he took a leading part in resisting the anti-republican policy of which the *Seize mai* incident was a symptom, and in 1879 demanded the indictment of the Broglie ministry. In 1880 he started his newspaper, *La Justice*, which became the principal organ of Parisian Radicalism; and from this time onwards throughout Grévy's presidency his reputation as a political critic, and as a destroyer of ministries who yet would not take office himself, rapidly grew. He led the extreme Left in the Chamber. He was an active opponent of Jules Ferry's colonial policy and of the Opportunist party, and in 1885 his use of the Tongking disaster principally determined the fall of the Ferry cabinet. At the elections of 1885 he was returned both for his old seat in Paris and for the Var, selecting the latter. Refusing to form a ministry to replace the one he had overthrown, he supported the Right in keeping Freycinet in power in 1886, and was responsible for the inclusion of Gen. Boulanger in the Freycinet cabinet as war minister. When Boulanger (*q.v.*) showed his real colours, Clemenceau became a vigorous opponent of the Boulangist movement, though the Radical press and a section of the party continued to patronize the general.

By his exposure of the Wilson scandal (see GRÉVY) Clemenceau contributed to Grévy's resignation of the presidency in 1887, having declined Grévy's request that he should himself form a cabinet on the downfall of that of Rouvier; and he was primarily responsible, by advising his followers to vote neither for Floquet, Ferry nor Freycinet, for the election of an "outsider" as president in Carnot. But the split in the Radical party over Boulangism weakened his hands, and his relations with Cornelius Herz in the Panama affair involved him in the general suspicion. However, though he remained the leading spokesman of French Radicalism, his hostility to the Russian alliance so increased his unpopularity that in the election for 1893 he was defeated for the Chamber. Clemenceau now confined his political activities to journalism, his career being further overclouded by the Dreyfus case, in which he was an active supporter of Zola and an opponent of the anti-Semitic and Nationalist campaign. In 1900 he withdrew from *La Justice* to found a weekly review, *Le Bloc*, which lasted until March 1902. On April 6, 1902, he was elected senator for the Var, although he had previously continually demanded the suppression of the Senate. He sat with the Socialist Radicals, and vigorously supported the Combes ministry. In June 1903 he undertook the direction of the journal *L'Aurore*, which he had founded. In it he led the campaign for the revision of the Drey-

fus affair, and for the separation of Church and State.

In March 1906 the fall of the Rouvier ministry, owing to the riots provoked by the inventories of church property, at last brought Clemenceau to power as minister of the interior in the Sarrien cabinet. The strike of miners in the Pas de Calais after the disaster at Courrières, leading to the threat of disorder on May 1, 1906, induced him to employ the military; and his attitude in the matter alienated the Socialist party, from which he definitely broke in his notable reply in the chamber to Jean Jaurès in June 1906. This speech marked him out as the "strong man" of the day in French politics; and when the Sarrien ministry resigned in October, he became premier. During 1907 and 1908 the new *entente* with England was cemented, and France played a great part in European politics, in spite of difficulties with Germany and attacks by the Socialist party in connection with Morocco (see FRANCE: History). But on July 20, 1909, Clemenceau was defeated in a discussion in the chamber on the state of the navy, and was succeeded as premier by Briand, with a reconstructed cabinet.

Two years later Clemenceau entered the Senate and became a member of its commissions for foreign affairs and the army. He could have had no better position for surveying European fluctuations and German activities; or for inquiry into the real condition of French armaments—this last his dominant concern. Convinced that Germany meant war, he was haunted by the fear that again France might be caught unprepared. The Senate, however, gave little opportunity for sounding the alarm. Accordingly, on May 5, 1913, appeared a new daily paper, *L'Homme Libre*, its editor—Georges Clemenceau. In its pages he waged daily battle for security and liberty. Though *L'Homme Libre* dealt every day with home politics and social problems, it returned always to the terrible theme of the German menace.

In the spring of 1913 the question of restoring the three years' term of conscript service suddenly arose. Clemenceau took an impassioned part in the debates on armaments. Then came Aug. 1914 and the World War. *L'Homme Libre* soon suffered at the hands of the Censor for Clemenceau's plain speaking. The whole youth of France must be mobilized. He denounced the shirkers, demanded technical efficiency, and attacked all incompetency, red tape, inadequate munition factories, with their shortage of guns and rifles, and badly-run hospitals. He made war in short, upon all who failed to realize that this was a conflict of supplies and organization, and upon every kind of apathy and feebleness. The result was that in Sept. 1914 *L'Homme Libre* was suppressed. Two days later, however, it reappeared as *L'Homme Enchaîné*, but wore its fetters lightly. For three months there was a daily struggle with the Censor. For some time not a week passed without articles being mutilated, but Clemenceau won and excisions became rare. Meanwhile in the Senate, Clemenceau agitated for more and still more guns, munitions, soldiers, for a judicious use of the available man-power and for a better equipped and better organized medical service.

But above all he strove to create the indomitable and desperate "will to victory." He was supported by other members of the army and foreign affairs commission, like Chéron, Doumer, Humbert, Berenger. The war dragged on; weariness, slackness and pacifism began to appear. Clemenceau was the first to draw public attention to that growing peril and it was at a public debate in the Senate on July 22, 1917, that he made his famous attack on Malvy, who had been Minister of the Interior since 1914. Clemenceau declared that Malvy had not treated revolutionaries with a firm enough hand. Malvy's justification was that he desired to "gain the confidence of the working-man"; but Clemenceau retorted that there was no comparison between those working-men who were loyally doing their duty to their country and a number of abject "defeatists."

Four months later Clemenceau came into power. He had never sought office and he knew that his task meant victory or death. When Clemenceau became premier the situation was miserable. The moral at the front was bad, and at home even worse. Resources were nearly at an end, and no solution whatever could be discerned. Poincaré realized that of all men Clemenceau was

the impersonation of the idea of war to the death. In his new Government Clemenceau himself took the portfolio of minister of war. He was 76 years of age when he formed his "victory cabinet" on Nov. 16, 1917, and thenceforward till Nov. 11, 1918, Clemenceau did in fact concentrate on war only. He made it clear that France was bent on absolute victory and would brook no half-measures. Those who spoke of wavering or yielding were immediately silenced; any one who obstructed the path to victory was ruthlessly removed. By these means Clemenceau restored the nation's self-confidence, and with it the conviction that its martyrdom would not be in vain. In March 1918 the Anglo-French line was broken through; Clemenceau joined in organizing the unity of command with Foch at the head. In May came the disaster of the Chemin des Dames; the French troops were driven back on the Marne, while the commander-in-chief was criticised. Three months later Clemenceau made Foch Marshal of France. During that long year of ceaseless effort Clemenceau's resolution remained unshaken. On Nov. 8, 1918, Erzberger was in the train of the Commander-in-chief of the allied armies. On the 11th the guns roared for the last time; the nightmare was over.

From Nov. 11, 1918, to June 28, 1919, Clemenceau devoted himself to the international settlement. The Peace of Versailles was in preparation, and this necessitated strenuous days of work and delicate negotiations. Up till now Clemenceau had merely had to contend with his enemies; now his task was to reconcile the interests of France with those of her friends. He defended her cause with enthusiasm and conviction, forcing his view alternatively on Lloyd George and President Wilson. Meanwhile Germany was disarming, and Clemenceau took care to supervise that disarmament. But the French parliament began to grow restless, for it saw itself put to one side in the peace negotiations. It therefore no longer regarded Clemenceau as indispensable. The great patriot, who was anxious to finish the work he had begun, did his best to smooth matters over. Momentous problems had to be solved; demobilization had to be faced, a general election was looming ahead, and the questions of Alsace-Lorraine and the liquidation of war stocks had to be settled. Clemenceau decided to deal simultaneously with these questions as of equal importance.

Peace was signed on June 28, and on Nov. 11 the new chamber was elected. Clemenceau counted on its support; for he believed that its members, many of them ex-soldiers, would have profited by the lesson of the war. Although he never stood as a candidate it is certain that he would have been ready to give the last years of his life by taking Poincaré's place at the Elysée, so that outside and above the changing Governments, he could have secured continuity in political action by a strict application of the 1919 treaties.

Poincaré left the Elysée but Deschanel was elected President of the French republic. And without doubt the Chambers had voted according to their hearts. Clemenceau had saved his country, but members could not forgive the fact that he had excluded them from the final work for victory. During the war he had undoubtedly worked alone; he felt that large assemblies were not made for action. Probably he would have admitted the commissions to the deliberations on the Treaty of Versailles if diplomatic obstacles had not intervened to prevent it. Clemenceau had also to face the hostility, not only of the clerical party of the Right who suspected him of indifference to the Vatican, but also that of the extreme Left, who were alienated by what they considered to be his militarism. Clemenceau thus met the fate which overtook other war ministers, and on Jan. 20, 1920, his cabinet fell, Millerand being summoned to office. He had earned the gratitude of his country and, returning to his beloved books, might well have sought repose; instead he sailed for India. After his journey he returned to Paris and to his books.

But it now appeared that the United States was endeavouring to dissociate herself from European affairs. Clemenceau was now 81 years old, but he sailed at once for America at the end of 1922. From town to town he carried the message of France to the citizens of the Union. He had no official mission, for he had neither asked anything nor received anything from the French

Government. His progress was none the less triumphant. Once more he returned to Paris but not to rest. By the end of 1925 he was already writing two books; one on philosophy, *Au Soir de la Pensée* (1927), English translation, *In the Evening of my Thought* (1929), and the other on Demosthenes, *Demosthène* (1926, Eng. trans. by C. M. Thompson, 1926). He was at work upon his memoirs, *Grandeurs et Misères d'un Victoire* (1930), when he died in Paris on Nov. 24, 1929. (J. Mt.)

CLEMENCÍN, DIEGO (1765–1834), Spanish scholar and politician, was born at Murcia, and educated there at the Colegio de San Fulgencio. In 1807 he became editor of the *Gaceta de Madrid*, and in the following year was condemned to death by Murat for publishing a patriotic article; he fled to Cadiz, and under the Junta Central held various posts from which he was dismissed by the reactionary government of 1814. During the liberal régime (1820–23) Clemencín took office as colonial minister, was exiled till 1827, and in 1833 published the first volume of his edition (1833–39) of *Don Quixote*.

CLEMENS, SAMUEL L.: see **TWAIN, MARK.**

CLEMENT, the name of 14 popes and two anti-popes.

CLEMENT I., Saint, generally known as Clement of Rome, or **CLEMENS ROMANUS** (fl. c. A.D. 96), was one of the "Apostolic Fathers," and in the lists of bishops of Rome is given the third or fourth place—Peter, Linus (Anencletus), Clement. There is no ground for Origen's identification of him with the Clement of Phil. iv. 3. He may have been a freedman of T. Flavius Clemens, who was consul with his cousin, the emperor Domitian, in A.D. 95. He is commemorated on Nov. 23.

In *The Shepherd of Hermas* mention is made of one Clement whose office it is to communicate with other churches, and this function agrees well with what we find in the letter to the church at Corinth by which Clement is best known. The letter was occasioned by a dispute which had led to the ejection of several presbyters, and while it does not contain Clement's name, there is no reason for doubting the universal tradition which ascribes it to Clement, or the generally accepted date, c. A.D. 96. Though the Roman Church claims no superior rank, it is noteworthy that in the earliest document outside the canon which we can securely date, it comes forward as a peacemaker in the troubles of a church in Greece. Nothing is known of the cause of the discontent, and the dismissal of the presbyters is regarded by Clement as high-handed and unjustifiable. After praising the Corinthian Church, Clement enters upon a denunciation of vices and a praise of virtues, and illustrates his topics by copious citations from the Old Testament scriptures, a fact which points to his being a Christian of long standing. Near the end of the letter (it is twice the length of the Epistle to the Hebrews) he rebukes the present disorders. The letter closes with a long liturgical prayer, which almost certainly represents the intercession used in the Roman eucharists. He knows that the roots of the quarrel lie in a wrong condition of the Church's life, and his general exhortations are directed towards a reformation of manners. The most permanent interest of the epistle lies in its being a 1st century account of the grounds on which the Christian ministry rests. The orderliness of nature is appealed to as expressing the mind of its Creator. The orderliness of Old Testament worship bears a like witness; everything is duly fixed by God. Similarly in the Christian dispensation all is in order due.

We learn from the letter (i. 7) that the Church at Rome, though persecuted, was firmly held together by faith and love. The epistle was publicly read from time to time at Corinth, and by the 4th century this usage had spread to other churches. It is attached to the famous Alexandrian ms. (Codex A) of the New Testament, but this does not imply that it ever reached canonical rank. For the mass of early Christian literature that was gradually attached to Clement's name see **CLEMENTINE LITERATURE.**

The epistle was published in 1633 by P. Young from Cod. Alexandrinus, in which a leaf near the end was missing, so that the great prayer (cc. lv.–lxiv.) remained unknown. In 1875 (six years after J. B. Lightfoot's first edition) Bryennius (q.v.) published a complete text from a Constantinople ms. dated 1055 from which in 1883, he gave us the *Didachê*. In 1876 R. L. Bensly found a complete Syriac text in a ms. in the University library, Cambridge. Lightfoot made

use of these new materials in an Appendix (1877) (2nd ed. with excellent excursus and Eng. trans. in *The Apostolic Fathers* vol. i., 1890). Dom Morin discovered a Latin version (1894), probably of the 3rd century, which is a valuable addition to the authorities for the text. Its evidence is used in the edition by R. Knopf (Leipzig, 1899). See also W. Wrede, *Untersuchungen zum ersten Clemensbrief* (1891), and other literature cited in Herzog-Hauck's *Realencyklopädie*.

CLEMENT II. (Suidger) became pope on Dec. 25, 1046. He belonged to a noble Saxon family, was bishop of Bamberg, and chancellor to the emperor Henry III., who elevated him to the papacy. He was the first pope placed on the throne by the power of the German emperors, but his short pontificate was only signalized by the convocation of a council in which decrees were enacted against simony. He died on Oct. 9, 1047.

CLEMENT III. (Paolo Scolari), pope from 1187 to 1191, a Roman, and cardinal bishop of Palestrina, was chosen pope on Dec. 19, 1187. In 1189 he made peace with the emperor Frederick I. Barbarossa. He settled a controversy with William of Scotland concerning the choice of the archbishop of St. Andrews, and in March 1188 removed the Scottish Church from the legatine jurisdiction of the archbishop of York, thus making it independent of all save Rome. He annoyed Henry VI. of Germany by bestowing Sicily on Tancred.

See "Epistolae et Privilegia," in Migne, *Patrol. Lat.* 204, 1,253 ff.; *Neues Archiv für die ältere deutsche Geschichtskunde*, 2, 219; 6, 293; 14, 178-182; Jaffé, *Regesta Pontificum Romanorum*, tom. 2 (1888), 535 ff.; J. Geyer, *Papst Klemens III.* (Bonn, 1914).

CLEMENT IV. (Gui Foulques), pope from 1265 to 1268, son of a lawyer, was born at St. Gilles-sur-Rhône. He became a valued legal adviser of Louis IX. of France, and after the death of his wife took orders. In 1257 he was made bishop of Le Puy, in 1259 archbishop of Narbonne, and in 1261 cardinal bishop of Sabina. He was appointed legate in England in 1263, and before his return was elected pope at Perugia on Feb. 5, 1265. He invested the avaricious Charles of Anjou with the kingdom of Sicily, but subsequently came into conflict with him after the death of Manfred in Feb. 1266. When Conradin, the last of the Hohenstaufen, appeared in Italy the pope excommunicated him and his supporters. Clement died at Viterbo on Nov. 29, 1268, leaving a name unsullied by nepotism. As the protector of Roger Bacon he has a special title to the gratitude of posterity.

See A. Potthast, *Regesta Pontificum Romanorum*, vol. ii. (1875), 1,542 ff.; E. Jordan, *Les Régistres de Clement IV.* (1893 ff.); Herzog-Hauck, *Realencyklopädie*; J. Heidemann, "Papst Clemens IV.," in *Kirchengeschichtliche Studien*, 6. Band (Münster, 1903), and C. Nicholas, *Clément IV.* (Nîmes, 1910).

CLEMENT V. (Bertrand de Gouth), pope from 1305 to 1314, was born of a noble Gascon family about 1264. After studying at Toulouse, Orleans, and Bologna, he became a canon at Bordeaux, then vicar-general to his brother, the archbishop of Lyons, in 1295 bishop of Cominges, and in 1299 archbishop of Bordeaux. On June 5, 1305, he was chosen to succeed Benedict XI. From the beginning Clement V. was subservient to French interests. Among his first acts was the creation of nine French cardinals. Early in 1306 he modified those features of the bulls *Clericus Laicos* and *Unam sanctam*, which were offensive to the king. In March 1309 the entire papal court settled at Avignon, a fief of the king of Sicily. Thus began the 70 years "Babylonian captivity of the Church." In Oct. 1307 came the arrest of all the Knights Templar in France, whom the king had charged with heresy, immorality and abuses. Fearing that the State would proceed independently against the alleged heretics, Clement summoned the council of Vienne (see VIENNE, COUNCIL OF), which was unable to conclude that the Templars were guilty of heresy. The pope abolished the order, however, as it had outlived its usefulness. Its French estates were granted to the Hospitallers, but actually Philip IV. held them until his death.

In his relations to the empire Clement was an opportunist. He refused to favour the candidature of Charles of Valois, brother of Philip IV., lest France became too powerful; and recognized Henry of Luxemburg, whom his representatives crowned emperor at the Lateran in 1312. When Henry, however, came into conflict with Robert of Naples, Clement supported Robert and threatened the emperor with interdict. Henry's unexpected death

was soon followed by that of the pope on April 20, 1314, at Roquemaure-sur-Rhône.

See *Regestum Clementis Papae V. ex Vaticanis archetypis cura et studio monachorum ord. Ben.* (Rome, 1885-92, 9 vols. and appendix); J. Gmelin, *Schuld oder Unschuld des Templerordens* (Stuttgart, 1893); J. Loserth, *Geschichte des späteren Mittelalters* (Munich, 1903); and A. Eitel, *Der Kirchenstaat unter Klemens V.* (Berlin, 1907); G. Lizerand, *Clément V.* (1911).

CLEMENT VI. (Pierre Roger), pope from May 7, 1342, to Dec. 6, 1352, was born at Maumont, Limousin, in 1291, joined the Benedictines as a boy, studied at Paris, and became successively prior of St. Baudil, abbot of Fécamp, bishop of Arras, chancellor of France, archbishop of Sens and archbishop of Rouen. He was made cardinal-priest of St. Nereo ed Achilleo and administrator of the bishopric of Avignon by Benedict XII. in 1338, and four years later succeeded him as pope. Clement continued the struggle of his predecessors with the emperor Louis the Bavarian, excommunicating him in April 1346, and directing the election of Charles of Moravia, who received general recognition after the death of Louis in 1347, and put an end to the schism which had long divided Germany. Clement carried on fruitless negotiations for Church unity with the Armenians and with the Greek emperor, John Cantacuzenus. He tried to end the Hundred Years' War between England and France, but secured only a temporary truce. He excommunicated Casimir of Poland for marital infidelity and forced him to do penance. He successfully resisted encroachments on ecclesiastical jurisdiction by the kings of England, Castile and Aragon. He secured full ownership of the county of Avignon through purchase from Queen Joanna of Naples and renunciation of feudal claims by Charles IV. of France, and considerably enlarged the papal palace in that city. To supply money for his undertakings Clement revived the practice of selling reservations and expectancies, which had been abolished by his predecessor. Oppressive taxation, and unblushing nepotism were Clement's great faults. On the other hand, he was famed for his engaging manners, eloquence and theological learning. He died on Dec. 6, 1352.

See Baluzius, *Vitae Papae Avenion.*, vol. i. (Paris, 1693); E. Werunsky, *Excerpta ex registris Clementis VI. et Innocentii VI.* (Innsbruck, 1885); F. Cerasoli, *Clemente VI. e Giovanni I. di Napoli—Documenti inedite* (1896, etc.); J. B. Christophe, *Histoire de la papauté pendant le XIV^e siècle*, vol. ii. (1853) and J. Gay, *Le Pape Clement VI. et Les Affaires d'Orient* (1904).

CLEMENT VII. (Giulio de' Medici), pope from 1523 to 1534, was the son of Giuliano de' Medici, assassinated in the Pazzi conspiracy at Florence. In 1494 Giulio went with Lorenzo the Magnificent into exile; but, on Giovanni's restoration to power, returned to Florence, of which he was made archbishop by his cousin, Pope Leo X., a special dispensation being granted on account of his illegitimate birth, followed by a formal declaration of the fact that his parents had been secretly married and that he was therefore legitimate. In 1513 he was made cardinal, and during the pontificate of Leo had practically the whole papal policy in his hands. On the death of Adrian VI. he was chosen pope (Nov. 18, 1523). It soon became clear, however, that Clement was only a good second in command, for though he was cultured and economical without being avaricious, he was essentially a man of narrow outlook and interests. Instead of bending his mind to the problem of the Reformation, he subordinated the cause of Catholicism to his interests as an Italian prince and a Medici; and even in purely secular affairs his timidity and indecision prevented him from pursuing a consistent policy.

His accession at once brought about a political change in favour of France. He wavered between the emperor and Francis I., concluding a treaty of alliance with the French king, and then after the defeat of Pavia making his peace with Charles (April 1, 1525), but breaking it again by countenancing Girolamo Morone's League of Freedom, which aimed to assert Italian independence. On the betrayal of this conspiracy Clement made a fresh submission to the emperor, only to follow this, a year later, by the Holy League of Cognac with Francis I. (May 22, 1526). Then followed the imperial invasion of Italy and Bourbon's sack of Rome (May 1527). The pope himself was besieged and compelled to ransom himself with 400,000 scudi, and to promise to convene a general

council to deal with Lutheranism. After the treaty of Cambrai on Aug. 3, 1529, Charles met Clement at Bologna and received from him the imperial crown and the iron crown of Lombardy, but the pope for some time exercised his temporal power in subservience to the emperor. Clement was now mainly occupied in urging Charles to arrest the progress of the Reformation in Germany and in efforts to elude the emperor's demand for a general council, which Clement feared lest the mode of his election and his legitimacy should be raised. Owing to his dependence on Charles V., Clement evaded Henry VIII.'s demand for the nullification of his marriage with Catherine and so brought about the breach between England and Rome. He died on Sept. 25, 1534.

CLEMENT VII. (Robert of Geneva) (d. 1394), antipope, after occupying the episcopal sees of Théroutanne and Cambrai, became a cardinal. In 1378 he took part in the election of Pope Urban VI. at Rome, and was perhaps the first to express doubts as to the validity of that tumultuous election. When the cardinals resolved to regard Urban VI. as an intruder and the Holy See as still vacant, Robert of Geneva was elected pope on Sept. 20, 1378, and took the name of Clement VII. Thus originated the Great Schism of the West.

Clement was supported by Queen Joanna of Naples, several Italian barons and Charles V. of France, and he eventually succeeded in winning to his cause Scotland, Castile, Aragon, Navarre, a great part of the Latin East, and Flanders. To wrest Rome from his rival, Clement incited Louis, duke of Anjou, the eldest of the brothers of Charles V., to take arms in his favour, by the bait of a kingdom to be carved expressly out of the States of the Church and to be called the kingdom of Adria, coupled with the expectation of succeeding to Queen Joanna. These tempting offers gave rise to a series of expeditions into Italy of which the most decisive result was the assuring of Provence to the dukes of Anjou and afterwards to the kings of France.

Before his death (Sept. 16, 1394), Clement realized the impossibility of overcoming by brute force an opposition which was founded on the convictions of the greater part of Catholic Europe.

See N. Valois, *La France et le grand schisme d'occident* (1896).

CLEMENT VIII. (Ippolito Aldobrandini), pope from 1592 to 1605, was born at Fano in 1535. He became a jurist and in 1585 was made a cardinal. On Jan. 30, 1592, he was elected pope, to succeed Innocent IX. To emancipate the papacy from undue Spanish influence, Clement cultivated closer relations with France. In 1595 he granted absolution to Henry IV., and so removed the last objection to the acknowledgment of his legitimacy. The peace of Vervins (1598), which ended the opposition of Philip II. to Henry, was mainly his work. He remonstrated against the exclusion of the Jesuits from France, and obtained their re-admission. Upon the failure of the line of Este, Clement claimed the reversion of Ferrara and re-incorporated it into the States of the Church (1598). His hopes of recovering England through James I. were never realized. Under Clement the publication of the revised edition of the Vulgate, begun by Sixtus V., was finished; the Breviary, Missal and Pontifical revised; the Index was expanded; the Vatican library enlarged; and the Collegium Clementinum founded. Clement was an unblushing nepotist, but, on the other hand, promoted to the cardinalate such men as Baronius, Bellarmine and Toledo. He died on March 5, 1605.

See the contemporary *Vita* by Ciaconius (Rome, 1601); Francolini, *Ippolito Aldobrandini che fu Clemente VIII.* (Perugia, 1867); Ranke's *Popes* (Eng. trans. Austin), ii. 234 seq.; v. Reumont, *Gesch. der Stadt Rom*. iii. 2, 599 seq.; Brosch, *Gesch. des Kirchenstaates* (1880), i. 301 seq.

CLEMENT VIII. (Aegidius Muñoz), antipope from 1425 to July 26, 1429, was a canon at Barcelona until elected by three cardinals created by the antipope Benedict XIII. Clement was recognized by Alphonso V. of Aragon, who was hostile to Pope Martin V. on account of the latter's opposition to his claims to the kingdom of Naples. When Alphonso and Martin became reconciled, Clement abdicated and spent his last years as bishop of Majorca. He died on Dec. 28, 1446.

See L. Pastor, *History of the Popes*, vol. i. (1899); M. Creighton, *History of the Papacy*, vol. ii. (1899); and bibl. on MARTIN V.

CLEMENT IX. (Giulio Rospigliosi) was born in 1600, became successively auditor of the Rota, archbishop of Tarsus in partibus, and cardinal, and was elected pope on June 20, 1667. He effected a temporary adjustment of the Jansenist controversy; was instrumental in concluding the peace of Aix-la-Chapelle (1668); healed a long-standing breach between the Holy See and Portugal; aided Venice against the Turks, and laboured unceasingly for the relief of Crete, the fall of which hastened his death on Oct. 9, 1669.

See Oldoin, continuator of Ciaconius, *Vitae et res gestae summorum Pontiff. Rom.*; Palazzi, *Gesta Pontiff. Rom.* (Venice, 1687-88), iv. 621 seq. (both contemporary); Ranke, *Popes* (Eng. trans. Austin), iii. 59 seq.; and v. Reumont, *Gesch. der Stadt Rom*. iii. 2, 634 seq.; C. Terlinden, *Le Pape Clément IX.* (1904).

CLEMENT X. (Emilio Altieri) was born in Rome on July 13, 1590. Before becoming pope, on April 29, 1670, he had been auditor in Poland, governor of Ancona, and nuncio in Naples. His advanced age induced him to resign the control of affairs to his adopted nephew, Cardinal Paluzzi, who embroiled the papacy in disputes with the resident ambassadors, and incurred the enmity of Louis XIV., thus provoking the long controversy over the regalia (see INNOCENT VI.). Clement died on July 22, 1676.

See Guarnacci, *Vitae et res gestae Pontiff. Rom.* (Rome, 1751), (contin. of Ciaconius), i. 1 seq.; Palazzi, *Gesta Pontiff. Rom.* (Venice, 1687-88), iv. 655 seq.; and Ranke, *Popes* (Eng. trans. Austin), iii. 172 seq.; Bildt, *Christine de Suède et le Conclave de Clem. X.* (1906).

CLEMENT XI. (Giovanni Francesco Albani), pope from 1700 to 1721, was born in Urbino on July 22, 1649, and after filling various important offices in the Curia became pope on Nov. 23, 1700, succeeding Innocent XII. His private life and his administration were blameless, but it was his misfortune to reign in troublous times. In the war of the Spanish Succession he would willingly have remained neutral, but was forced first to recognize Philip V., then driven by the emperor to recognize the archduke, Charles. In the peace of Utrecht he was ignored; Sardinia and Sicily, Parma and Piacenza, were disposed of without regard to papal claims. When he quarrelled with the duke of Savoy, and revoked his investiture rights in Sicily (1715), his interdict was treated with contempt. Clement reaffirmed papal infallibility in matters of fact (1705), and in 1713 issued the bull *Unigenitus*, condemning 101 Jansenistic propositions. (See JANSENISM and QUESNEL, PASQUIER.) He also forbade missionaries in China to "accommodate" their teachings to pagan notions in order to win converts. Clement was a generous patron of art and letters.

See Elci, *The Present State of the Court of Rome* (trans. 1706); Polidoro, *De Vita et Reb. Gest. Clem. XI.* (Urbino, 1727); Reboulet, *Hist. de Clem. XI. Pape* (Avignon, 1752); Guarnacci, *Vitae et res gest. Pontiff. Rom.* (Rome, 1751); Sandini, *Vitae Pontiff. Rom.* (Padua, 1739); Buder, *Leben u. Taten Clementis XI.* (Frankfurt, 1720-21); *Clementis XI. Opera Omnia* (Frankfurt, 1729); Pometti, "Studi sul pontificato di Clem. XI." in the *Archivio della R. Soc. romana di storia patria*, vols. xxi.-xxiii. (1898-1900), and bibl. in Hergenröther, *Allg. Kirchengesch.* iii. 506 (1880).

CLEMENT XII. (Lorenzo Corsini), pope from 1730 to 1740, succeeded Benedict XIII. on July 12, 1730. Clement laboured for a union with the Greek Church, and was ready to facilitate the return of the Protestants of Saxony. His services to learning and art include the restoration of the Arch of Constantine, the enrichment of the Capitoline museum with antique marbles and inscriptions, and of the Vatican library with oriental manuscripts

(see ASSEMANI); and the embellishment of the city with many buildings. He died on Feb. 6, 1740.

See Guarnacci, *Vitae et res gestae Pontiff. Rom.* (Rome, 1751); Sandini, *Vitae Pontiff. Rom.* (Padua, 1739); Fabroni, *De Vita et Reb. Gest. Clementis XII.* (Rome, 1760); Ranke, *Popes* (Eng. trans. Austin), iii. 191 seq.; v. Reumont, *Gesch. der Stadt Rom.*, iii. 2, 653 seq.

CLEMENT XIII. (Carlo della Torre Rezzonico), pope from 1758 to 1769, was born in Venice on March 7, 1693, filled various important posts in the Curia, became cardinal in 1737, bishop of Padua in 1743, and succeeded Benedict XIV. as pope on July 6, 1758. He was a man of upright and pacific intentions, but his pontificate was anything but tranquil. The Jesuits, who had been expelled from Portugal, France, Spain, the Two Sicilies and Parma, turned to the pope as their natural protector; but his protests (cf. the bull *Apostolicum pascendi munus* of Jan. 1765) were unheeded (see JESUITS). A clash with Parma aggravated his troubles. The Bourbon kings espoused their relative's quarrel, seized Avignon, Benevento and Ponte Corvo, and demanded the suppression of the Jesuits (Jan. 1769). Clement consented to call a Consistory but died on Feb. 2, 1769.

See Augustin de Andrés y Sobías, . . . *el nacimiento, estudios y empleos de . . . Clem. XIII.* (Madrid, 1759); Ravignan's *Clement XIII. et Clement XIV.* (Paris, 1854) is partisan, but appends many interesting documents. See also the bibl. of Clement XIV. *infra*; and that in Hergenröther, *Allg. Kirchengesch.* (1880), iii. 509.

CLEMENT XIV. (Lorenzo Ganganelli), pope from 1769 to 1774, son of a physician of St. Arcangelo, near Rimini, was born on Oct. 31, 1705, joined the Franciscans, and as regent of the college of S. Bonaventura, Rome, came under the notice of Benedict XIV., who made him consultor of the Inquisition. Clement XIII. made him a cardinal, and in May 1769 he was elected pope.

The outlook for the papacy was dark; Portugal was talking of a patriarchate; France held Avignon; Naples held Ponte Corvo and Benevento; Spain was ill-affected; Parma, defiant; Venice, aggressive; Poland meditating a restriction of the rights of the nuncio. Clement realized the imperative necessity of conciliating the Powers. He suspended the public reading of the bull *In Coena Domini*, so obnoxious to civil authority; resumed relations with Portugal; revoked the *monitorium* of his predecessor against Parma. But the Powers were bent upon the destruction of the Jesuits, and they had the pope at their mercy. Clement looked abroad for help, but found none. Even Maria Theresa, his last hope, suppressed the Order in Austria. Convinced that the peace of the Church demanded the sacrifice, Clement signed the brief *Dominus ac Redemptor*, dissolving the Jesuit Order, on July 21, 1773. The Powers at once gave proof of their satisfaction; Benevento, Ponte Corvo, Avignon and the Venaissin were restored to the Holy See. But it would be unfair to accept this as evidence of a bargain. Clement had formerly indignantly rejected the suggestion of such an exchange of favours. Whatever the guilt or innocence of the Jesuits, and whether their suppression were ill-advised or not, there appears to be no ground for impeaching the peace motives of Clement, or of doubting that he had the approval of his conscience.

The suppression of the Jesuits bulks so large in the pontificate of Clement that he has scarcely been given due credit for his praiseworthy attempt to reduce the burdens of taxation and to reform the financial administration, nor for his liberal encouragement of art and learning, of which the museum Pio-Clementino is a lasting monument.

Clement's was a deeply religious, refined and benevolent nature. He cherished high purposes, but instinctively shrank from conflict; he lacked the resoluteness and the stern courage that grapple with a crisis. He died from natural causes on Sept. 22, 1774.

See Theiner, *Clementis XIV. Epistolae et Brevia* (1852); Caraccioli's *Vie de Clément XIV.* (1775) (freq. trans.), is uncritical. St. Priest's *Hist. de la chute des Jésuites* (1846), represents Clement as lamentably weak; Creteineau-Joly's *Hist. . . de la Comp. de Jésus* (1844) and his *Clément XIV. et les Jésuites* (1847), was outspoken and bitter and provoked Theiner's *Gesch. des Pontificats Clemens' XIV.* (Leipzig and Paris, 1852), a vigorous defence based upon original documents of the Vatican; Creteineau-Joly replied with *Le Pape Clément XIV.; Lettres au P. Theiner* (1852). See also v. Reumont, *Ganganelli, Pape*

Clemens XIV. (Berlin, 1847); and Reinerding, *Clemens XIV. u. d. Aufhebung der Gesellschaft Jesu* (Augsburg, 1854). Hergenröther, *Allg. Kirchengesch.* (1880), iii. 510 seq. gives an extended bibliography.

CLÉMENT, FRANÇOIS (1714–1793), French historian, was born at Bèze, near Dijon. He became a Benedictine and wrote vols. xi. and xii. of the *Histoire littéraire de la France*, and edited (with Dom Brial) vols. xii. and xiii. of the *Recueil des historiens des Gaules et de la France*. The king appointed him to the committee for the publication of charters and other historical documents. Of his revision of the *Art de vérifier les dates* (ed. 1750 by Dom Clémencet), 3 vols. with indexes appeared from 1783 to 1792. Clément died at Paris on March 29, 1793.

CLÉMENT, JACQUES (1567–1589), murderer of the French king Henry III., was born at Sorbon in the Ardennes, and became a Dominican friar. His mind appears to have become unhinged by religious fanaticism, and he formed a plan to kill Henry III. Having obtained letters for the king, he left Paris on July 31, 1589, and reached St. Cloud, the headquarters of Henry, who was besieging Paris. While Henry was reading the letters Clément mortally wounded him with a dagger which had been concealed beneath his cloak. The assassin was killed on the spot by the king's attendants.

CLÉMENTEL, ÉTIENNE (1862–), French politician, was born on March 29, 1862, at Riom and educated there. He was elected a deputy in 1898 and became minister for the colonies in Rouvier's cabinet in 1905, afterwards occupying ministerial posts in departments where his knowledge of economics could find full play, the ministries of agriculture, colonies, finance, public works and marine. His collaboration was particularly valuable in organizing the supply of raw materials for the allied armies during the World War. By effecting the agreement for establishment of the inter-allied wheat executive with Walter Runciman in Nov. 1916, Clémentel helped to tide over a difficult situation. The creation of the inter-allied maritime transport council was due in great part to his energy, for, as early as Aug. 1917, he had occupied himself with drawing up a general inventory of his own country's requirements, an initiative quickly followed by the allied governments. After the armistice, Clémentel was chosen "Président fondateur" of the International Chamber of Commerce. He was elected senator for Puy de Dôme in 1918. His work at the London Conference of July 1924, which he attended as minister of finance in the Herriot cabinet, was greatly appreciated. He resigned office as minister of finance on April 3, 1925, on the ground of a difference with Herriot on the question of a fresh issue of notes by the Bank of France. In 1927 he was president of the finance committee of the Senate and also became a member of the committee on trade barriers of the International Chamber of Commerce. Among his writings may be mentioned: *L'Âme celtique* (1899) and *Un drame économique* (1914).

CLEMENTI, MUZIO (1752–1832), Italian pianist and composer, was born at Rome where his father was a jeweller. At nine he was appointed organist of a church and at fourteen he had written a mass which was performed in public. About 1766 Peter Beckford, cousin of the author of *Vathek*, brought Clementi to England, where his success both as composer and pianist was rapid and brilliant. In 1777 he was for some time employed as conductor of the Italian opera, but he soon afterwards left London for Paris. Here also his concerts were crowded by enthusiastic audiences, and the same success accompanied him on a tour about the year 1780 to southern Germany and Austria. At Vienna, which he visited between 1781 and 1782, he was received with high honour by the emperor Joseph II., in whose presence he met Mozart, and fought a kind of musical duel with him.

In May 1782 Clementi returned to London, where for the next twelve years he continued his lucrative occupations of fashionable teacher and performer at the concerts of the aristocracy. He took shares in the pianoforte business of a firm which went bankrupt in 1800. He then established a pianoforte and music business of his own, under the name of Clementi & Co. which was very successful. Other members were added to the firm, including Collard and Davis, and it was ultimately taken over by Collard.

Amongst his pupils on the pianoforte during this period may be mentioned John Field, the composer of the celebrated *Nocturnes*. In his company, Clementi paid, in 1804, a visit to Paris, Vienna, St. Petersburg [Leningrad], Berlin and other cities. While he was in Berlin, Meyerbeer became one of his pupils. He also revisited his own country, after an absence of more than thirty years. In 1810 Clementi returned to London, but refused to play again in public, devoting the remainder of his life to composition. Several symphonies belong to this period but none was published.

Of Clementi's playing in his youth, Moscheles wrote that it was "marked by a most beautiful *legato*, a supple touch in lively passages, and a most unflinching technique." Mozart may be said to have closed the old and Clementi to have founded the newer school of technique on the piano. Amongst Clementi's compositions the most remarkable are sixty sonatas for pianoforte, and the great collection of *Études* called *Gradus ad Parnassum*.

CLEMENTINE LITERATURE, the name generally given to the writings which at one time or another were fathered upon Pope Clement I. (q.v.), commonly called Clemens Romanus, who was early regarded as a disciple of St. Peter. Chief among them are: (1) The so-called Second Epistle; (2) two Epistles on Virginity; (3) the *Homilies and Recognitions*, with which may be classed the *Epistle of Clement to James*; (4) the *Apostolical Constitutions* (q.v.); and (5) five epistles forming part of the Forged Decretals (see DECRETALS). The present article deals mainly with the third group, to which the title "Clementine literature" is usually confined, owing to the stress laid upon it in the famous Tübingen reconstruction of primitive Christianity, in which it played a leading part; but later criticism has lowered its importance as its true date and historical relations have been progressively ascertained. (1) and (2) became "Clementine" only by chance, but (3) was so originally by literary device or fiction, the cause at work also in (4) and (5). But while in all cases the suggestion of Clement's authorship came ultimately from his prestige as writer of the genuine Epistle of Clement (see CLEMENT I.), both (3) and (4) were due to this idea as operative on Syrian soil; (5) is a secondary formation based on (3) as known to the West.

(1) *The Second Epistle of Clement*.—This is really the earliest extant Christian homily (see APOSTOLIC FATHERS). Its theme is the duty of Christian repentance, with a view to obedience to Christ's precepts as the true confession and homage which He requires. Its special charge is "Preserve the flesh pure and the seal (i.e., baptism) unstained" (viii. 6). But the peculiar way in which it enforces its morals in terms of the Platonic contrast between the spiritual and sensuous worlds, as archetype and temporal manifestation, and the fact that the preacher seems to quote the *Gospel according to the Egyptians* (in ch. xii. and possibly elsewhere) as if familiar to his hearers, and indeed its literary affinities generally, all point to Alexandria as the original home of the homily, at a date about 120-140.

(2) *The Two Epistles to Virgins*, i.e., to Christian celibates of both sexes. These are known in their entirety only in Syriac, and were first published by Wetstein (1752), who held them genuine. This view is now generally discredited, even by Roman Catholics like Funk, their best recent editor (*Patres Apost.*, vol. ii.). There is no trace of their use in the West. Their Syrian origin is manifest, the more so that in the Syriac ms. they are appended to the New Testament, like the better-known epistles of Clement in the Codex Alexandrinus. Special occasion for such hortatory letters may be discerned in their polemic against intimate relations between ascetics of opposite sex, implied to exist among its readers, in contrast to usage in the writer's own locality. Now we know that spiritual unions, prompted originally by highstrung Christian idealism as to a religious fellowship transcending the law of nature in relation to sex, did exist between persons living under vows of celibacy during the 3rd century in particular, and not least in Syria (cf. the case of Paul of Samosata, c. 265, and the Synod of Ancyra in Galatia, c. 314).

(3a) *The Epistle of Clement to James* (the Lord's brother). This was originally part of (3b), in connection with which its origin and date are discussed. But as known to the West through Rufinus' Latin version, it was quoted as genuine throughout the

middle ages. It became the starting point of the most momentous and gigantic of mediaeval forgeries, the Isidorian Decretals, where it stands at the head of the pontifical letters, extended to more than twice its original length.

(3b) *The Homilies and Recognitions*.—"The two chief extant Clementine writings, differing considerably in some respects in doctrine, are both evidently the outcome of a peculiar speculative type of Judaistic Christianity, for which the most characteristic name of Christ was 'the true Prophet.' The framework of both is a narrative purporting to be written by Clement (of Rome) to St. James, the Lord's brother, describing at the beginning his own conversion and the circumstances of his first acquaintance with St. Peter, and then a long succession of incidents accompanying St. Peter's discourses and disputations, leading up to a romantic recognition of Clement's father, mother and two brothers, from whom he had been separated since childhood. The problems discussed under this fictitious guise are with rare exceptions fundamental problems for every age; and, whatever may be thought of the positions maintained, the discussions are hardly ever feeble or trivial. Regarded simply as mirroring the past, few, if any, remains of Christian antiquity present us with so vivid a picture of the working of men's minds under the influence of the new heaven which had entered into the world" (Hort, *Clem. Recogn.*, p. xiv.). Recent criticism builds on the principle, which emerges alike from the external and internal evidence that both writings used a common basis or parent document. Towards the determination of its nature, origin and antecedents, two contributions of prime importance have been made. The earlier of these is by F. J. A. Hort, and was delivered in the form of lectures as far back as 1884, though issued posthumously only in 1901; the other is the elaborate monograph of Dr. Hans Waitz (1904).

External Evidence.—The evidence of ancient writers really begins, not with Origen, but with Eusebius of Caesarea, who in his *Eccl. Hist.* iii. 38, writes as follows: "Certain men have quite lately brought forward as written by him (Clement) other verbose and lengthy writings, containing dialogues of Peter, forsooth, and Apion, whereof not the slightest mention is to be found among the ancients, for they do not even preserve in purity the stamp of the Apostolic orthodoxy." Apion, the Alexandrine grammarian and foe of Judaism, whose criticism was answered by Josephus, appears in this character both in *Homilies* and *Recognitions*, though mainly in the former (iv. 6-vii. 5). Thus Eusebius implies (1) a spurious Clementine work containing matter found also in our *Homilies* at any rate; and (2) its quite recent origin. Next we note that an extract in the *Philocalia* of Origen is introduced as follows: "Yea, and Clement the Roman, a disciple of Peter the Apostle, after using words in harmony with these on the present problem, in conversation with his father at Laodicea in the *Circuits*, speaks a very necessary word touching this matter" (astrological divination). The extract answers to *Recognitions*, x. 10-13, but it is absent from our *Homilies*. Here we observe that (1) the extract agrees this time with *Recognitions*, not with *Homilies*; (2) its framework is that of the Clementine romance found in both; (3) the tenth and last book of *Recognitions* is here parallel to book xiv. of a work called *Circuits* (*Periodoi*). This last point leads on naturally to the witness of Epiphanius (c. 375), who, speaking of Ebionites or Judaizing Christians of various sorts, and particularly the Essene type, says (*Haer.* xxx. 15) that "they use certain other books likewise, to wit, the so-called *Circuits* of Peter, which were written by the hand of Clement. . . . In the *Circuits*, then, they adapted the whole to their own views, representing Peter falsely in many ways, as that he was daily baptized for the sake of purification, as these also do; and they say that he likewise abstained from animal food and meat, as they themselves also do." Now all the points here noted in the *Circuits* can be traced in our *Homilies* and *Recognitions*, though toned down in different degrees. The witness of the Arianizing *Opus Imperfectum in Matthaeum* (c. 400) is in general similar. Its usual form of citation is "Peter in Clement" (*apud Clementem*), and points to "Clement" as a brief title for the Clementine *Periodoi*.

It has been needful to cite so much of the evidence proving

that our *Homilies* and *Recognitions* are both recensions of a common basis, at first known as the *Circuits of Peter* and later by titles connecting it rather with Clement, its ostensible author, because it affords data also for the historical problems touching (a) the contents and origin of the primary Clementine work, and (b) the conditions under which our extant recensions of it arose.

(a) *The Circuits of Peter*, as defined on the one hand by the epistle of Clement to James originally prefixed to it and by patristic evidence, and on the other by the common element in our *Homilies* and *Recognitions*, may be conceived as follows. It contained accounts of Peter's teachings and discussions at various points on a route beginning at Caesarea, and extending northwards along the coast-lands of Syria as far as Antioch. During this tour he meets with persons of typically erroneous views, which it was presumably the aim of the work to refute in the interests of true Christianity, conceived as the final form of divine revelation—a revelation given through true prophecy embodied in a succession of persons, the chief of whom were Moses and the prophet whom Moses foretold, Jesus the Christ. The prime exponent of the spurious religion is Simon Magus. A second protagonist of error, this time of Gentile philosophic criticism directed against fundamental Judaism, is Apion, the notorious anti-Jewish Alexandrine grammarian of Peter's day; while the rôle of upholder of astrological fatalism (*Genesis*) is played by Faustus, father of Clement, with whom Peter and Clement debate at Laodicea. Finally, all this is already embedded in a setting determined by the romance of Clement and his lost relatives, "recognition" of whom forms the *dénouement* of the story.

There is no reason to doubt that such, roughly speaking, were the contents of the Clementine work to which Eusebius alludes slightly, in connection with that section of it which had to his eye least verisimilitude, viz., the dialogues between Peter and Apion. Now Eusebius believed the work to have been of quite recent and suspicious origin. This points to a date about the last quarter of the 3rd century; and the prevailing doctrinal tone of the contents, as known to us, leads to the same result. The standpoint is that of the peculiar Judaizing Christianity due to persistence among Christians of the tendencies known among pre-Christian Jews as Essene. The Essenes, while clinging to what they held to be original Mosaism, yet conceived and practised their ancestral faith in ways which showed distinct traces of syncretism, or the operation of influences foreign to Judaism proper. They thus occupied an ambiguous position on the borders of Judaism. Similarly Christian Essenism was syncretist in spirit, as we see from its best-known representatives, the Elchasaïtes, of whom we first hear about 220, when a certain Alcibiades of Apamea in Syria (some 60m. south of Antioch) brought to Rome the *Book of Helxai*—the manifesto of their distinctive message (Hippol., *Philos.* ix. 13)—and again some 20 years later, when Origen refers to one of their leaders as having lately arrived at Caesarea (Euseb. vi. 38).

The *Periodoi* or *Circuits* must not be thought of as strictly Elchasaïte, since it knew no baptism distinct from the ordinary Christian one. It seems rather to represent a later and modified Essene Christianity, already half Catholic, such as would suit a date after 250, in keeping with Eusebius's evidence. Confirmation of such a date is afforded by the silence of the Syrian *Didascalia*, itself perhaps dating from about 250, as to any visit of Simon Magus of Caesarea, in contrast to the reference in its later form, the *Apostolical Constitutions* (c. 350–400), which is plainly coloured (vi. 9) by the Clementine story. On the other hand, the *Didascalia* seems to have been evoked partly by Judaizing propaganda in north Syria. If, then, it helps to date the *Periodoi* as after 250, it may also suggest as place of origin one of the large cities lying south of Antioch, say Laodicea (itself on the coast about 30m. from Apamea), where the Clementine story reaches its climax. The intimacy of local knowledge touching this region implied in the narrative common to *Homilies* and *Recognitions* is notable, and tells against an origin for the *Periodoi* outside Syria (e.g., in Rome, as Waitz and Harnack hold, but Lightfoot disproves, *Clem.* i. 55 f., 64, 100, cf. Hort, p. 131). Further, though the curtain even in it fell on Peter at Antioch itself (our one com-

plete ms. of the *Homilies* is proved by the *Epitome*, based on the *Homilies*, to be here abridged), the interest of the story culminates at Laodicea.

If we assume, then, that the common source of our extant Clementines arose in Syria, perhaps, c. 265, had it also a written source or sources which we can trace? Though Hort doubts it, most scholars (e.g., Waitz, Harnack) infer the existence of at least one source, "Preachings (*Kerygmata*) of Peter," containing no reference at all to Clement. Such a work seems implied by the epistle of Peter to James and its appended adjuration, prefixed in our mss. to the *Homilies* along with the epistle of Clement to James. Thus the later work aimed at superseding the earlier, much as Photius suggests (see above). It was, then, to these "Preachings of Peter" that the most Ebionite features, and especially the anti-Pauline allusions under the guise of Simon still inhering in the *Periodoi* (as implied by *Homilies* in particular), originally belonged. The fact, however, that these were not more completely suppressed in the later work, proves that it, too, arose in circles of kindred, though largely modified, Judaeo-Christian sentiment (cf. *Homilies*, vii., e.g., ch. 8). The differences of standpoint may be due not only to lapse of time, and the emergence of new problems on the horizon of Syrian Christianity generally, but also to change in locality and in the degree of Greek culture represented by the two works. A probable date for the "Preachings" used in the *Periodoi* is c. 200.

If the home of the *Periodoi* was the region of the Syrian Laodicea, we can readily explain most of its characteristics. Photius refers to the "excellences of its language and its learning"; while Waitz describes the aim and spirit of its contents as those of an apology for Christianity against heresy and paganism, in the widest sense of the word, written in order to win over both Jews (cf. *Recognitions*, i. 53–70) and pagans, but mainly the latter. In particular it had in view persons of culture, as most apt to be swayed by the philosophical tendencies in the sphere of religion prevalent in that age, the age of neo-Platonism. It was in fact designed for propaganda among religious seekers in a time of singular religious restlessness and varied inquiry, and, above all, for use by catechumens (cf. *Ep. Clem.* 2, 13) in the earlier stages of their preparation for Christian baptism. To such its romantic setting would be specially adapted, as falling in with the literary habits and tastes of the period; while its doctrinal peculiarities would least give offence in a work of the aim and character just described.

(b) That the *Periodoi* was a longer work than either our *Homilies* or *Recognitions* is practically certain; and its mere bulk may well, as Hort suggests, have been a chief cause of the changes of form. Yet *Homilies* and *Recognitions* are abridgments made on different principles and convey rather different impressions to their readers. The *Homilies* care most for doctrine, especially philosophical doctrine, and seem to transpose very freely for doctrinal purposes; the *Recognitions* care most for the story, as a means of religious edification, and have preserved the general framework much more nearly. They arose in different circles; indeed, save the compiler of the text represented by the Syriac ms. of A.D. 411 (who gives a selection of discourses from the *Homilies* after *Recognitions*, iii.), not a single ancient writer shows a knowledge of both books in any form. Both probably arose in Syria (so Lightfoot), but in circles varying a good deal in religious standpoint. *Homilies* was a sort of second edition, made largely in the spirit of its original and perhaps in much the same locality, with a view to maintaining and propagating the doctrines of a semi-Judaic Christianity (cf. bk. vii.), as it existed a generation or two after the *Periodoi* appeared. The *Recognitions*, in both recensions, as is shown by the fact that it was read in the original with general admiration not only by Rufinus but also by others in the West, was more Catholic in tone.

The Clementine literature throws light upon a very obscure phase of Christian development, that of Judaeo-Christianity, and proves that it embraced more intermediate types, between Ebionism proper and Catholicism, than has generally been realized. Incidentally, too, its successive forms illustrate many matters of belief and usage among Syrian Christians generally in the 3rd

and 4th centuries, notably their apologetic and catechetical needs and methods. Further, it discusses, as Hort observes, certain indestructible problems which much early Christian theology passes by or deals with rather perfunctorily; and it does so with a freshness and reality which we see to be not unconnected with origin in an age as yet free from the trammels of formal orthodoxy. The romance to which it owed much of its popular appeal, became, through the medium of Rufinus' Latin, the parent of the late mediaeval legend of Faust, and so the ancestor of a famous type in modern literature.

Literatur* (1904), ii. 518f. In English, besides Hort's work, there are articles by G. Salmon, in *Dict. of Christ. Biog.*, C. Bigg, *Studia Biblica*, ii., A. C. Headlam, *Journal of Theol. Studies*, iii., and in Hastings' *Encyclopædia of Religion and Ethics*.

CLEMENT OF ALEXANDRIA (*Clemens Alexandrinus*) was probably born about A.D. 150 of heathen parents in Athens. The earliest writer after himself who gives us any information with regard to him is Eusebius (d. 370). The only points on which his works now extant inform us are his date and his instructors. In the *Stromateis* ("Miscellanies"), while attempting to show that the Jewish scriptures were older than any writings of the Greeks, he invariably brings down his dates to the death of Commodus (192), a circumstance which at once suggests that he wrote in the reign of the emperor Severus, from 193 to 211 (see *Strom.* lib. i. cap. xxi. 140). We know nothing of his conversion except that it occurred, for his writings show a singularly minute acquaintance with the ceremonies of pagan religion, and there are indications that he himself had been initiated into some of the mysteries (*Protrept.* cap. ii. sec. 14). He attained the position of presbyter in the church of Alexandria (Eus. *H.E.* vi. 11, and Jerome, *De Vir. Ill.* 38), and became perhaps the assistant, and certainly the successor of Pantæus in the catechetical school of that place. Among his pupils were Origen (Eus. *H.E.* vi. 7) and Alexander, bishop of Jerusalem (Eus. *H.E.* vi. 14). How long he continued in Alexandria, and when and where he died, are all matters of pure conjecture.

Clement occupies a profoundly interesting position in the history of Christianity. He is the first to bring all the culture of the Greeks and all the speculations of the Christian heretics to bear on the exposition of Christian truth. The list of Greek authors from whom he quoted occupies upwards of 14 of the 410. pages in Fabricius's *Bibliotheca Graeca*. He is at home alike in the epic and the lyric, the tragic and the comic poets, his knowledge of the prose writers is very extensive, and he made a special study of the philosophers. Equally minute is his knowledge of the systems of the Christian heretics; and it is plain that he not merely read but thought deeply on the questions which the civilization of the Greeks and the various writings of poets, philosophers and heretics raised. It was, however, in the Scriptures, which he held contained the revelation of God's wisdom to men, that he was most deeply read, yet, notwithstanding the great biblical knowledge evidenced by his works, the modern theologian is disappointed to find in them very little of what he deems distinctively Christian. In fact Clement regarded Christianity as a philosophy. The ancient philosophers sought through their philosophy to attain to a nobler and holier life, and this also was the aim of Christianity. The difference between the two, in Clement's judgment, was that the Greek philosophers had only glimpses of the truth, that they attained only to fragments of the truth, while Christianity revealed in Christ the absolute and perfect truth. All the stages of the world's history were therefore preparations leading up to this full revelation, and God's care was not confined to the Hebrews alone. The worship of the heavenly bodies, for instance, was given to man at an early stage that he might rise from a contemplation of these sublime objects to the worship of the Creator. Greek philosophy in particular was the preparation of the Greeks for Christ. It was the schoolmaster or pedagogue to lead them to Christ. Clement varies in his statement how Plato got his wisdom or his fragments of the Reason; sometimes he thinks that they came direct from God, like all good things,

but he is also fond of maintaining that many of Plato's best thoughts were borrowed from the Hebrew prophets; and he makes the same statement in regard to the wisdom of the other philosophers. But however this may be, Christ was the end to which all that was true in philosophies pointed. Christ himself was the Logos, the Reason. God the Father was ineffable. The Son alone can manifest Him fully. He is the Reason that pervades the universe, that brings out all goodness, that guides all good men. It was through possessing somewhat of this Reason that the philosophers attained to any truth and goodness; but in Christians he dwells more fully and guides them through all the perplexities of life. Photius, probably on a careless reading of Clement, argued that he could not have believed in a real incarnation. But the words of Clement are quite precise and their meaning indisputable. The real difficulty attaches not to the Second Person, but to the First. The Father in Clement's mind becomes the Absolute of the philosophers, not the Father of the Gospel at all. He believed in a personal Son of God who was the Reason and Wisdom of God; and he believed that this Son of God really became incarnate though he speaks of him almost invariably as the Word, and attaches little value to his human nature. The object of his incarnation and death was to free man from sin, to lead him into the path of wisdom, and thus in the end elevate him to the position of a god. But man's salvation was to be gradual. It began with faith, passed from that to love, and ended in full and complete knowledge. There could be no faith without knowledge; but the knowledge is imperfect, and the Christian has to do many things in simple obedience without knowing the reason. He has to move upwards continually until he at length does nothing that is evil and knows fully the reason and object of what he does. He thus becomes the true Gnostic, but he can become the true Gnostic only by contemplation and by the practice of what is right. He has to free himself from the power of passion; he has to give up all thoughts of pleasure; he must prefer goodness in the midst of torture to evil with unlimited pleasure; he must resist the temptations of the body, keeping it under strict control, and with the eye of the soul undimmed by corporeal wants and impulses, contemplate God the supreme good, and live a life according to reason. In other words, he must strive after likeness to God as he reveals himself in his Reason or in Christ. Clement thus looks entirely at the enlightened moral elevation to which Christianity raises man. He believed that Christ instructed men before he came into the world, and he therefore viewed heathenism with kindly eye. He was also favourable to the pursuit of all kinds of knowledge. All enlightenment tended to lead up to the truths of Christianity, and hence knowledge of every kind not evil was its handmaid. Clement had at the same time a strong belief in evolution or development. The world went through various stages in preparation for Christianity. The man goes through various stages before he can reach Christian perfection. And Clement conceived that this development took place not merely in this life, but in the future through successive grades. The Jew and the heathen had the gospel preached to them in the world below by Christ and His apostles, and Christians will have to pass through processes of purification and trial after death before they reach knowledge and perfect bliss.

Eusebius and Jerome give lists of the works which Clement left behind him. (1) Πρὸς Ἑλλήνας λόγος ὁ προτρεπτικός, *A Hortatory Address to the Greeks*; (2) Ὁ Παιδαγωγός, *The Tutor* in three books; (3) Στρωματεῖς ("patchwork"), or *Miscellanies*, in 8 books; (4) Τὸς ὁ σωζόμενος πλοῦσιος, *Who is the rich man that is saved?* (5) Ὑποτυπώσεις, *Adumbrations or Outlines* in 8 books; treatises on (6) *The Passover*, (7) *Fasting*, (8) *Slander*, (9) *Patience*, "for the newly baptised"; and (10) *On the Rule of the Church*, "for those who Judaize." Of these the first four have come down to us complete or nearly so. The *Address to the Greeks* contains an attack on the crudities and immoralities in the stories told of heathen deities, with an argument that the great thinkers and poets of Greece had recognized the unit and spirituality of the divine Being, and that fuller light had been revealed through the Hebrew prophets. In the *Paedagogus*, he explains how before the incarnation Christ

was gradually leading mankind to the Truth, and then explains how the Christian following the Logic or Reason ought to behave in the various circumstances of life. The contents of the *Miscellanies*, as the title indicates are very varied. Sometimes they discuss chronology, sometimes philosophy, sometimes poetry; but one object runs through all, to show what the true Christian Gnostic is, and what is his relation to philosophy. The tract *Who is the rich man that is saved?* is an admirable exposition of Mark x. 17-31. Clement argues that wealth, if rightly used, is not unchristian. Of the remaining books mentioned by Eusebius, we know that the *Adumbrations* was a short commentary on all the books of Scripture, including some apocryphal books; and we have two fragments of the book on the *Passover*. Of the others nothing is known. We have also fragments of two treatises, on *Providence* and on the *Soul*, not named by Eusebius.

Patrick, *Clement of Alexandria* (1914). W. R. Inge, "Alexandrian Theology," in J. Hastings, *Encyclopaedia of Religion and Ethics* (1908), gives an excellent summary account of the Alexandrine School. The standard edition of the collected works is O. Stählin, *Clemens Alexandrinus* (Leipzig, 1905). We have a valuable separate edition of *Miscellanies*, bk. vii., ed. F. J. A. Hort and J. B. Mayor (1902), and of the tract on Wealth by P. M. Barnard, *Texts and Studies*, vol. 2 (Cambridge, 1897). See also B. F. Westcott, "Clement of Alexandria" *Murray's Dictionary of Christian Biography* (1911).

CLEMENTS, FREDERICK EDWARD (1874–), American plant oecologist, was born in Lincoln, Neb., Sept. 16, 1874. He graduated in 1894 at the University of Nebraska from which in 1898 he received the degree of doctor of philosophy. From 1894 to 1906 he was instructor and associate professor of botany and in 1906–07 he was professor of plant physiology, at the University of Nebraska. He was professor of botany and head of the botanical department in the University of Minnesota from 1907 to 1917 when he was made associate in charge of oecological research in the Carnegie Institution of Washington. He has conducted extensive investigations in oecology, palaeo-oecology, experimental evolution and climatology. Among his published works are: *The Phytogeography of Nebraska*, with Roscoe Pound (1898, 2nd ed., 1900); *Development and Structure of Vegetation* (1904); *Research Methods in Ecology* (1906); *Plant Physiology and Ecology* (1907); *Minnesota Mushrooms* (1910); *Rocky Mountain Flowers*, with Edith Clements (1913); *Plant Succession* (1916); *Plant Indicators* (1920); *The Phylogenetic Method in Taxonomy*, with H. M. Hall (1923); *Plant Succession and Indicators* (1927); and *Flower Families and Ancestors* (1927).

CLEOBULUS, one of the Seven Sages of Greece, a native and tyrant of Lindus in Rhodes. He was distinguished for his strength and his handsome person, for the wisdom of his sayings, the acuteness of his riddles, and the beauty of his lyric poetry. Diogenes Laërtius quotes a letter in which Cleobulus invites Solon to take refuge with him against Peisistratus; and this would imply that he was alive in 560 B.C. He is said to have held advanced views as to female education, and he was the father of the wise Cleobuline, whose riddles were not less famous than his own (Diogenes Laërtius, i. 89–93).

See F. G. Mullach, *Fragmenta Philosophorum Graecorum*, i.

CLEOMENES, the name of three Spartan kings of the Agiad line (Κλεομένης).

CLEOMENES I. was the son of Anaxandridas, whom he succeeded about 520 B.C. His chief exploit was his crushing victory near Tiryns over the Argives, some 6,000 of whom he burned to death in a sacred grove to which they had fled for refuge (Herodotus vi. 76–82). This secured for Sparta the undisputed hegemony of the Peloponnese. Cleomenes' interposition in the politics of central Greece was less successful. In 510 he marched to Athens with a Spartan force to aid in expelling the peisistratidae, and subsequently returned to support the oligarchical party, led by Isagoras, against Cleisthenes (q.v.). He expelled 700 families and transferred the government from the council to 300 of the oligarchs, but being blockaded in the Acropolis was forced to capitulate. On his return home he collected a large force, with the intention of making Isagoras despot of Athens, but the opposition

of the Corinthian allies, and of his colleague, Demaratus, caused the expedition to break up after reaching Eleusis (Herod. v. 64–76; Aristotle, *Ath. Pol.* 19, 20). In 491 he went to Aegina to punish the island for its submission to Darius, but the intrigues of his colleague once again rendered his mission abortive. In revenge Cleomenes accused Demaratus of illegitimacy and secured his deposition in favour of Leotyichides (Herod. vi. 50–73). But when it was discovered that he had bribed the Delphian priestess to substantiate his charge he was himself obliged to flee; he went first to Thessaly and then to Arcadia, where he attempted to foment an anti-Spartan rising. About 488 B.C. he was recalled, but shortly afterwards, in a fit of madness, he committed suicide (Herod. vi. 74, 75). Cleomenes seems to have received scant justice at the hands of Herodotus or his informants, and Pausanias (iii. 3, 4) does little more than condense Herodotus' narrative. In spite of some failures, largely due to Demaratus' jealousy, Cleomenes strengthened Sparta in the position, won during his father's reign, of champion and leader of the Hellenic race; it was to him, for example, that the Ionian cities of Asia Minor first applied for aid in their revolt against Persia (Herod. v. 49–51).

The chief ancient authority is Herodotus (v. and vi.). See E. M. Walker, *Cambridge Ancient History*, vol. iv., ch. vi., § 1, 4, 5, and ch. viii., § 8). For chronology see J. Wells, *Journal of Hellenic Studies* (1905), p. 193 ff., who assigns the Argive expedition to the outset of the reign, whereas nearly all historians have dated it in or about 495 B.C.

CLEOMENES II. was the son of Cleombrotus I., brother and successor of Agesipolis II. Nothing is recorded of his reign save the fact that it lasted for nearly 61 years (370–309 B.C.).

CLEOMENES III., the son and successor of Leonidas II., reigned about 235–219 B.C. He made a determined attempt to reform the social condition of Sparta along the lines laid down by Agis IV., whose widow, Agiatis, he married; at the same time he aimed at restoring Sparta's hegemony in the Peloponnese. After twice defeating the forces of the Achaean league in Arcadia, near Mount Lycaenum and at Leuctra, he strengthened his position by assassinating four of the ephors, abolishing the ephorate, which had usurped the supreme power, and banishing some 80 of the leading oligarchs. The authority of the council was also curtailed, and a new board of magistrates, the *patronomi*, became the chief officers of state. He appointed his own brother, Eucleidas, as his colleague in succession to the Eurypontid Archidamus, who had been murdered. His social reforms included a redistribution of land, the remission of debts, the restoration of the old system of training ἀγωγή and the admission of picked *perioeci* (q.v.) into the citizen body. As a general Cleomenes did much to revive Sparta's old prestige. He defeated the Achaeans at Dyme, made himself master of Argos, and was eventually joined by Corinth, Phlius, Epidaurus and other cities. But Aratus, whose jealousy could not brook to see a Spartan at the head of the Achaean league, called in Antigonus Doson, of Macedonia, and Cleomenes, after conducting successful expeditions to Megalopolis and Argos, was finally defeated at Sellasia, to the north of Sparta, in 222 or 221 B.C. He took refuge at Alexandria with Ptolemy Euergetes, but was arrested by his successor, Ptolemy Philopator, on a charge of conspiracy. Escaping from prison he tried to raise a revolt, but the attempt failed, and to avoid capture he put an end to his life. Both as general and as politician Cleomenes was one of Sparta's greatest men, and with him perished her last hope of recovering her ancient supremacy in Greece.

See Polybius ii. 45–70, v. 35–39, viii. 1; Plutarch, *Cleomenes*; Aratus, 35–46; *Philopoemen*, 5, 6; Pausanias ii. 9; Holm, *History of Greece*, iv. cc. 10, 15. (M. N. T.)

CLEON (d. 422 B.C.), Athenian politician during the Peloponnesian War, was the son of Cleaenetus, from whom he inherited a tannery. He was the first prominent representative of the commercial class in Athenian politics. He came into notice first as an opponent of Pericles, and in his opposition somewhat curiously found himself acting in concert with the aristocrats, who equally hated and feared Pericles. In 430, when the city was devastated by the plague, Cleon headed the opposition to the Periclean régime. Pericles was accused of maladministration of public money, with the result that he was actually found guilty

though he was re-elected in 429. The death of Pericles (429) left the field clear for Cleon. Hitherto he had only been a vigorous opposition speaker, a critic and accuser of state officials. He now came forward as the champion and leader of the democracy, and, was for some years undoubtedly the foremost man in Athens. He was gifted with natural eloquence and a powerful voice, and knew how to work upon the feelings of the people. He became the leader of the war party in opposition to Nicias and the moderates, who favoured a cautious strategy and an early peace.

In 427 when Mytilene, which had revolted, fell, Cleon proposed that all its citizens should be put to death, and the women and children enslaved. His policy was to hold down the empire, now a "tyranny," by naked force. His decree was passed, but rescinded next day, in time to save Mytilene.

In 425 he, when the Spartans were blockaded in Sphacteria, brought about the rejection of the terms offered by Sparta, and in the hope of securing a peace which should restore Athens' land-empire. He then reached the summit of his fame by capturing the Spartans on the island (*see* PYLOS). Much of the credit of this success, the most notable which the Athenians won during the Archidamian War, was due to the military skill of his colleague Demosthenes; but it was due to Cleon's determination that the Ecclesia sent out the additional force which was needed. About this time Cleon doubled the tribute of the allies (*see* DELIAN LEAGUE) and raised the pay of the Athenian jurors from two to three obols (Schol. Ar. *Wasps* 88). In 422, after the close of the armistice, Cleon, who was eager to continue the war, went to recover Thrace from Brasidas, but, after capturing several cities, was taken by surprise at Amphipolis, defeated and killed. With his death, the peace party at Athens gained power, and the Peace of Nicias was concluded. (*See* PELOPONNESIAN WAR).

Cleon is represented by Aristophanes and Thucydides in an extremely unfavourable light. But neither can be considered an unprejudiced witness. Aristophanes was not only opposed to Cleon's political programme, but bore him a personal grudge, having been prosecuted by the demagogue after the production of his *Babylonians*. Moreover, his treatment of Socrates should put us on our guard against accepting his evidence against Cleon. Thucydides had been exiled by a decree proposed by Cleon after the loss of Amphipolis.

West and D. B. Meritt, "Cleon's Amphipolitan Campaign" (*American Journal of Archaeology* xxix. 1925).

CLEOPATRA, the regular name of the queens of Egypt, in the Ptolemaic dynasty after Cleopatra, daughter of the Seleucid Antiochus the Great, wife of Ptolemy V., Epiphanes. The best-known was the daughter of Ptolemy XIII., Auletes, born 69 (or 68) B.C. At the age of 17 she became queen of Egypt jointly with her younger brother Ptolemy Dionysus, whose wife, in accordance with Egyptian custom, she was to become. A few years later, deprived of all royal authority, she withdrew into Syria, and prepared to recover her rights by force of arms. At this juncture Julius Caesar followed Pompey into Egypt. The personal fascinations of Cleopatra induced him to undertake a war on her behalf, in which Ptolemy lost his life, and she was replaced on the throne with a younger brother, of whom, however, she soon rid herself by poison. In Rome she lived openly with Caesar as his mistress, until his assassination, when, aware of her unpopularity, she returned to Egypt. Subsequently she became the ally and mistress of Mark Antony (*see* ANTONIUS). Their connection was highly unpopular at Rome, and Octavian (*see* AUGUSTUS) declared war upon them and defeated them at Actium (31 B.C.). Cleopatra escaped to Alexandria, where Antony joined her. Having no pros-

pect of ultimate success, she accepted Octavian's proposal that she should assassinate Antony, and enticed him to join her in a mausoleum which she had built in order that "they might die together." Antony committed suicide, in the mistaken belief that she had already done so. Octavian refused to yield to the charms of Cleopatra, who put an end to her life by applying an asp to her bosom, according to the common tradition, on Aug. 29, 30 B.C. With her ended the dynasty of the Ptolemies, and Egypt was made a Roman province. Cleopatra had three children by Antony, and by Julius Caesar, it is said, a son, Caesarion, who was put to death by Octavian.

For the history of Cleopatra *see* ANTONIUS; CAESAR, GAIUS JULIUS; PTOLEMIES. The life of Antony by Plutarch is our main authority; it is upon this that Shakespeare's *Antony and Cleopatra* is based. Her life is the subject of monographs by Stahr (1879, an *apologia*), and H. Houssaye, *Aspasie, Cléopâtre*, etc. (1879).

CLEOPATRA'S NEEDLES, the name popularly given to the two Egyptian obelisks presented to the British and American people respectively, and now standing on the Thames Embankment in London and in the Central Park of New York city. Originally set up by Thotmes or Tethmosis III. at Heliopolis about 1500 B.C., they were removed by Caesar Augustus to adorn the Caesareum at Alexandria about 14 B.C. and there remained until removed (in each case by private munificence) to their present positions in 1878 and 1880. Both are of rose-red Syene granite, covered with hieroglyphical inscriptions, and are estimated to weigh some 200 tons. (*See* OBELISK.)

CLEPSYDRA, the chronometer of the Greeks and Romans, which measured time by the flow of water (Gr. κλέπτειν, to steal, and ὕδωρ, water). In its simplest form it was an earthenware globe of known capacity, pierced at the bottom with several small holes, through which the water escaped. It was employed to set a limit to speeches in courts of justice, hence the phrases *aquam dare* (Pliny, *Ep.* 6. 2. 7), to give the advocate speaking time, and *aquam perdere* (Quint. 11. 3. 52), to waste time.

The clepsydra is said to have been known to the Egyptians. There was one in the Tower of the Winds at Athens; the turret on the south side of the tower is supposed to have contained the cistern which supplied the water. *See* classical dictionaries, s.v.

BY COURTESY OF SHARPE, "SEVEN PERIODS OF ENGLISH ARCHITECTURE" (SPON); D'ESPLOY "MONUMENTS ANTIQUES" (MASSIN ET CIE); SIR BANISTER FLETCHER, "HISTORY OF ARCHITECTURE ON THE COMPARATIVE METHOD," EIGHTH ED. (1928) BATSFORD; ARCHITECTURAL BOOK PUB. CO.

EXAMPLES OF CLERESTORIES (SEE ARTICLE, CLERESTOREY ON NEXT PAGE)—A, B, exterior and interior, Peterborough cathedral, Romanesque clerestory; window at the top; C, Roman clerestory, tepidarium, Baths of Titus; D, modern adaptation of Roman type, the Pennsylvania Station, New York; E, Egyptian clerestory lighting, hypostyle hall, Karnak; F, G, exterior and interior, Winchester cathedral, showing larger Gothic clerestory.

CLERESTORY, CLERESTOREY or **CLEARSTORY**, in architecture, any wall of a room carried higher than the surrounding roofs so that windows can be pierced in it to light the room. In a large building, where interior walls are far from the outside of the building, some such method of lighting the central part becomes necessary, and the use of the clerestory appears as early, at least, as the 18th dynasty in Egypt, under which the great hypostyle hall of the temple at Karnak was built. This had a central range of columns, higher than those on either side, to allow clerestoreys to be built of pierced stone slabs. In Roman architecture, many great halls were thus lighted, usually groined vaults over the central hall allowed of large semicircular windows being built above the side roofs; e.g., S. Maria degli Angeli, at Rome (the tepidarium of the Baths of Diocletian) and the basilica of Constantine, at Rome. Similarly, the walls under the side arches of S. Sophia at Constantinople, are clerestorey walls. It was, however, in the Romanesque and Gothic churches of the middle ages, that the clerestorey idea received its most adequate expression. See p. 801 for illustrations of Clerestories. (See BYZANTINE AND ROMANESQUE ARCHITECTURE; GOTHIC ARCHITECTURE.)

CLERFAYT or **CLAIRFAYT, FRANÇOIS SEBASTIEN CHARLES JOSEPH DE CROIX**, COUNT OF (1733–1798), Austrian field marshal, entered the Austrian army in 1753. In the Seven Years' War he greatly distinguished himself, and in 1787 took part in the Turkish war. In 1792 he received the command of the Austrian contingent in the duke of Brunswick's army, and at Croix-sous-Bois his corps inflicted a reverse on the French. In the Netherlands he opened the campaign of 1793 with the victory of Aldenhoven and the relief of Maestricht, and on March 18 brought about the complete defeat of Dumouriez at Neerwinden. His victorious career was checked by the reverse at Wattignies, and in 1794 he was unsuccessful in West Flanders against Pichegru. Clerfayt succeeded the duke of Saxe-Coburg in the supreme command, but was quite unable to make head against the French, and had to recross the Rhine. In 1795, now field marshal, he commanded on the middle Rhine against Jourdan, whom he defeated at Höchst and Mainz. His action in concluding an armistice with the French not being approved by Thugut, he resigned the command, and became a member of the Aulic Council in Vienna. He died in 1798.

See von Vivenot, *Thugut, Clerfayt, und Würmser* (Vienna, 1869).

CLERGY, a collective term signifying strictly the body of "clerks," i.e., men in holy orders (see **CLERK**); but extended in modern times so as to embrace all varieties of ordained Christian ministers, though in England the word "clergyman" is still mainly restricted to the clergy of the Established Church. In the Roman Catholic Church the word, which is the O.Fr. *clergie*, from Low Lat. *clericatus*, embraces the whole hierarchy of *clerici*, whether in holy or merely minor orders; it has also been loosely used to include the members of religious orders. The M.E. senses of "clerkship" and "learning" have long been obsolete.

In distinction to the "clergy" we find the "laity" (Gr. *λαός*, people), the great body of "faithful people" which, in nearly every conception of the Christian Church, stands in relation to the clergy as a flock of sheep to its pastor. This distinction was of early growth, and developed during the middle ages into lively opposition (see **ORDER, HOLY**; **CHURCH HISTORY**; **PAPACY**; **INVESTITURES**). The extreme claim of the great mediaeval popes, that the priest, as "ruler over spiritual things," was as much superior to temporal rulers as the soul is to the body (see **INNOCENT III.**) led logically to the vast privileges and immunities enjoyed by the clergy, which consisted mainly in exemption from public burdens, both as regarded person and pocket, and in immunity from lay jurisdiction. This last privilege extended to matters both civil and criminal; though, as Bingham shows, it did not (always and everywhere) prevail in cases of heinous crime (*Origines Eccles.* bk. v.).

This subjection of the clergy only to courts disposed by *esprit de corps* to judge leniently led to the penalties for criminous clerks being much lighter than those to which laymen were amenable; and this in turn led to the survival in England, long after the Reformation, of the legal fiction of benefit of clergy, used to mitigate the harshness of the criminal law.

CLERGY, BENEFIT OF, an obsolete but once very important feature in English criminal law. Benefit of clergy began with the claim on the part of the ecclesiastical authorities in the 12th century that every *clericus* should be exempt from the jurisdiction of the temporal courts and be subject to the spiritual courts alone. The issue of the conflict was that the common law courts abandoned the extreme punishment of death assigned to some offences when the person convicted was a *clericus*, and the church was obliged to accept the compromise and let a secondary punishment be inflicted. The term "clerk" or *clericus* always included a large number of persons in what were called minor orders, and in 1350 the privilege was extended to secular as well as to religious clerks; and, finally, the test of being a clerk was the ability to read the opening words of verse 1 of Psalm li, hence generally known as the "neck-verse." Even this requirement was abolished in 1705. In 1487 it was enacted that every layman, when convicted of a clergyable felony, should be branded on the thumb, and disabled from claiming the benefit a second time. The privilege was extended to peers, even if they could not read, in 1547, and to women, partially in 1622 and fully in 1692. The partial exemption claimed by the Church did not apply to the more atrocious crimes, and hence offences came to be divided into clergyable and unclergyable. According to the common practice in England of working out modern improvements, through antiquated forms, this exemption was made the means of modifying the severity of the criminal law. It became the practice to claim and be allowed the benefit of clergy; and when it was the intention by statute to make a crime really punishable with death, it was awarded "without benefit of clergy." The benefit of clergy was abolished by a statute of 1827, but as this statute did not repeal that of 1547, under which peers were given the privilege, a further statute was passed in 1841 putting peers on the same footing as commons and clergy.

For a full account of benefit of clergy see Pollock and Maitland, *History of English Law*; Stephen, *History of the Criminal Law of England*; E. Friedberg, *Corpus juris canonici* (Leipzig, 1879–81).

CLERGYMAN, an ordained minister of the Christian Church. In England the term is usually confined to the ministers of the established Church. Educational qualifications for this work vary with the different denominations, but the majority require at least two or three years of religious specialization beyond a four year college course, with a growing tendency towards higher standards in general to meet the challenges of modern thought and inquiry. Good health, intellectual ability, moral integrity, a desire to serve, breadth of knowledge and understanding, spiritual conviction, love of humanity and poise are some of the personal attributes necessary inasmuch as the clergyman serves variously as preacher, leader of worship, teacher, educator, pastor, social worker and executive.

CLERGY RESERVES, in Canada. By the act of 1791, establishing the provinces of Upper and Lower Canada, the British Government set apart one-eighth of all the crown lands for the support of "a Protestant clergy." These reservations, after being for many years a stumbling-block to the economic development of the province, and the cause of much bitter political and ecclesiastical controversy, were secularized by the Canadian parliament in 1854, and the proceeds applied to other purposes, chiefly educational. Owing to the wording of the imperial act, the amount set apart is often stated as one-seventh, and was sometimes claimed as such by the clergy.

CLERK, SIR DUGALD (1854–), Scottish civil engineer, was born at Glasgow on March 31, 1854. He was educated at the West of Scotland Technical college and the Andersonian college. He invented the Clerk cycle gas engine in 1877, improving it in 1878 (see **GAS ENGINE**), and became an authority on internal combustion engines. He also interested himself in motor engineering. During the World War he became director of engineering research to the Admiralty, and until 1919 was a member of the advisory committee for aeronautics to the Air Ministry, and also of the air inventions committee. In 1908 he was elected F.R.S., and in 1917 knighted. His works include *The Gas and Oil Engine* and many scientific papers.

CLERK, in its original sense, as used in the civil law, one who had taken religious orders of whatever rank, whether "holy" or "minor." In English ecclesiastical law, a clerk was any one who had been admitted to the ecclesiastical state, and had taken the tonsure. The application of the word in this sense gradually underwent a change, and "clerk" became more especially the term applied to those in minor orders, while those in "major" or "holy" orders were designated in full "clerks in holy orders." After the reformation the word "clerk" was still further extended to include laymen who performed duties in cathedrals, churches, etc., e.g., the choirmen, who were designated "lay clerks." Of these lay clerks or choirmen there was always one whose duty it was to be constantly present at every service, to sing or say the responses as the leader or representative of the laity. His duties were gradually enlarged to include the care of the church and precincts, assisting at baptisms, marriages, etc., and he thus became the precursor of the later *parish clerk*. In a somewhat similar sense we find *bible clerk*, *singing clerk*, etc. The use of the word "clerk" to denote a person ordained to the ministry is now mainly legal.

From the fact that in mediaeval times learning was chiefly the province of the clergy, they were engaged in nearly all occupations requiring knowledge of writing combined with some education and hence the word "clerk" came to its present indefinite signification of a writer in the employment of some one else. Older and more specific use of the word is to be traced in *clerk of the market*, *clerk of the petty bag*, *clerk of the peace*, *town clerk*, etc.

CLERKE, AGNES MARY (1842-1907), English astronomer and scientific writer, was born on Feb. 10, 1842, and died in London on Jan. 20, 1907. Her chief works were *A Popular History of Astronomy during the 19th Century* (1885, 4th ed. 1902); *The System of the Stars* (1890, 2nd ed. 1905); and *Problems in Astrophysics* (1903). In 1903 she was elected an honorary member of the Royal Astronomical Society.

CLERKENWELL (klar'kĕn-wĕl), a district on the north side of the City of London, England, within the metropolitan borough of Finsbury (*q.v.*). It is so called from one of several wells or springs in this district, near which miracle plays were performed by the parish clerks of London. This well existed until the middle of the 19th century. Here was situated a priory, founded in 1100, which grew to great wealth and fame as the principal institution in England of the Knights Hospitallers of the Order of St. John of Jerusalem. Its gateway (1504), in St. John's Square, survived the suppression of the monasteries, and was the scene of Dr. Johnson's work in connection with the *Gentleman's Magazine*. In modern times the gatehouse again became associated with the Order, and is the headquarters of the St. John's Ambulance Association. An early English crypt remains beneath the neighbouring parish church of St. John, where the notorious deception of the "Cock Lane Ghost," in which Johnson took great interest, was exposed. Adjoining the priory was St. Mary's Benedictine nunnery, St. James's church (1792) marking the site. In the 17th century Clerkenwell became a fashionable place of residence. It has small watch-making and jeweller's industries, which have been long established here.

CLERMONT, a town of northern France, in the department of Oise, on the right bank of the Brèche, 41 m. N. of Paris on the Northern railway to Amiens. The town was probably founded during the time of the Norman invasions and was an important military post during the middle ages. It was several times taken and retaken during the Hundred Years' War, and the Wars of Religion. Pop. (1926) 3,864. The hill on which the town is built is surmounted by a keep of the 14th century, a relic of the once-famous fortress. The church dates from the 14th to the 16th centuries. The *hôtel-de-ville*, built by King Charles IV., who was born at Clermont in 1298, is the oldest in the north of France. The Promenade du Châtelier occupies the site of the old ramparts.

Clermont was at one time the seat of a countship, the lords of which were already powerful in the 11th century. Raoul de Clermont, constable of France, died at Acre in 1191, leaving a daughter who brought Clermont to her husband, Louis, count of Blois and Chartres. Theobald, count of Blois and Clermont, died in 1218 without issue, and King Philip Augustus, having received the

countship of Clermont from the collateral heirs of this lord, gave it to his son Philip Hurepel, whose daughter Jeanne, and his widow, Mahaut, countess of Dammartin, next held the countship. It was united by St. Louis to the crown, and afterwards given by him (1269) to his son Robert, from whom sprang the house of Bourbon. In 1524 the countship of Clermont was confiscated from the constable de Bourbon, and later (1540) given to the duke of Orléans, to Catherine de' Medici (1562), to Eric, duke of Brunswick (1569), from whom it passed to his brother-in-law Charles of Lorraine (1596), and finally to Henry II., prince of Condé (1611). In 1641 it was again confiscated from Louis de Bourbon, count of Soissons, then in 1696 sold to Louis Thomas Amadeus of Savoy, count of Soissons, in 1702 to Françoise de Brancas, princesse d'Harcourt, and in 1719 to Louis-Henry, prince of Condé. From a branch of the old lords of Clermont were descended the lords of Nesle and Chantilly.

CLERMONT-FERRAND, a city of central France, capital of the department of Puy-de-Dôme, 113 m. W. of Lyons, on the P.L.M. railway. Pop. (1906) 44,113; (1926) 101,529. Clermont-Ferrand is situated on high ground on the western border of the fertile plain of Limagne. On the north, west and south it is surrounded by hills, with a background of mountains amongst which the Puy-de-Dôme stands out prominently. A small river, the Tiretaine, borders the town on the north. Since 1731 it has been composed of the two towns of Clermont and Montferrand.

Gergovia was the native centre in Auvergne but the Roman settlement known as Augustonemetum on the site of Clermont became so important as to be called later "The city of the Arverni." The present name is derived from Clarus Mons originally applied only to the citadel, but used for the town as early as the 9th century. During the disintegration of the Roman empire Clermont suffered from capture and pillage. Its history during the middle ages chiefly records the struggles between its bishops and the counts of Auvergne, and between the citizens and their overlord the bishop. It was the seat of seven ecclesiastical councils, held in the years 535, 549, 587, 1095, 1110, 1124 and 1130. In the council of 1095 Pope Urban II. proclaimed the first crusade. It figured in the wars against the English in the 14th and 15th centuries and in the religious wars of the 16th century. *Les Grands Jours de Clermont* (1665) was associated with the trial and execution of a member of the nobility who had tyrannized the district. Before the Revolution the town possessed the abbey of Saint Allire, founded, it is said, in the 3rd century by St. Austremonius (St. Stremoine), the apostle of Auvergne and first bishop of Clermont, and the abbey of St. André, where the counts of Clermont were buried. The cathedral, a Gothic edifice, was begun in the 13th century. The stained glass dates from the 13th century. The church of Notre-Dame du Port is a typical example of the Romanesque style of Auvergne, dating chiefly from the 11th and 12th centuries. The exterior of the apse with its four radiating chapels, and its black and white decoration is the most interesting part. Among the old houses one, dating from the 16th century, was the birthplace of Blaise Pascal. Montferrand has several interesting houses of the 15th and 16th centuries, and a church of the 13th, 14th and 15th centuries. Clermont has several fine squares like the one erected by Bishop Jacques d'Amboise in 1515.

Clermont-Ferrand is the seat of a bishopric and a prefecture; it has tribunals of first instance and of commerce, a board of trade-arbitrators, and a chamber of commerce. It is a university town and has an important library, as well as the *Musée Lecoq* (natural history and geology) and the *Musée d'Art et d'Archéologie*. The town manufactures semolina and other farinaceous foods, confectionery, preserved fruit and jams, chemicals and heavy rubber goods, especially motor tyres. Clothing is also important. Clermont is the chief market for the grain and other agricultural produce of Auvergne and Velay. Its waters are in local repute. On the bank of the Tiretaine there is a remarkable calcareous spring, the fountain of St. Allire. About 1½ miles to the west lies the famous spa of Royat.

CLERMONT-GANNEAU, CHARLES SIMON (1846-1923); French Orientalist, the son of a sculptor of some repute,

was born in Paris, Feb. 19, 1846, and died Feb. 15, 1923. He laid the foundation of his reputation by his discovery (in 1870) of the "stele" of Mesha (Moabite Stone), which bears the oldest Semitic inscription known. In 1874 he was employed by the British Government to take charge of an archaeological expedition to Palestine, and was subsequently entrusted by his own government with similar missions to Syria and the Red sea. After serving as vice-consul at Jaffa from 1880 to 1882, he returned to Paris as "secrétaire-interprète" for oriental languages, and in 1886 was appointed consul of the first class. He subsequently accepted the post of director of the École des Langues Orientales and professor at the Collège de France. In 1889 he was elected a member of the Académie des Inscriptions et Belles Lettres, of which he had been a correspondent since 1880. In 1896 he was promoted to be consul-general, and was minister plenipotentiary in 1906. He was the first in England to expose the famous forgeries of Hebrew texts offered to the British Museum by M. W. Shapira (*q.v.*) in 1883, and in 1903 he took a prominent part in the investigation of the so-called "tiara of Saitapharnes." This tiara had been purchased by the Louvre for 400,000 francs, and exhibited as a genuine antique, but was agreed to be of modern manufacture.

His chief publications, besides a number of contributions to journals, are:—*Palestine inconnue* (1886), *Études d'archéologie orientale* (1880, etc.), *Les Fraudes archéologiques* (1885), *Recueil d'archéologie orientale* (1885–1924) *Album d'antiquités orientales* (1897, etc.).

CLERMONT-L'HÉRAULT, a town of southern France in the department of Hérault, 10 m. S.S.E. of Lodève. Pop. (1926) 4,994. The town is built on a hill crowned by an ancient castle and skirted by the Rhonel, a tributary of the Lergue. The church dates from the 13th and 14th centuries. Its woollen industry dates from the latter half of the 17th century. Tanning and leather-dressing are also carried on, and there is trade in wine. Among the public institutions are a tribunal of commerce, a chamber of arts and manufactures and a board of trade-arbitration. The town was several times taken and retaken in the religious wars of the 16th century.

CLERMONT-TONNERRE, STANISLAS MARIE ADELAIDE, COMTE DE (1757–1792), French politician, was born at Pont-à-Mousson on Oct. 10, 1757. Sent to the states-general in 1789 by the noblesse of Paris, he joined the Third Estate, and was elected president of the Constituent Assembly on Aug. 17, 1789. On the rejection by the Assembly of the scheme elaborated by the first constitutional committee, he attached himself to the party of moderate royalists, known as *monarchiens*, led by P. V. Malouet. His speech in favour of reserving to the crown the right of absolute veto under the new constitution drew down upon him the wrath of the advanced politicians of the Palais Royal; but he continued to advocate a moderate liberal policy, especially in the matter of removing the political disabilities of Jews and Protestants and of extending the system of trial by jury. In Jan. 1790 he collaborated with Malouet in founding the Club des Impartiaux and the *Journal des Impartiaux*, the names of which were changed in November to the Société des Amis de la Constitution Monarchique and *Journal de la Société*, etc., in order to emphasize their opposition to the Jacobins (Société des Amis de la Constitution). This club was denounced by Barnave in the Assembly (Jan. 21, 1791), and on March 28 it was attacked by a mob, whereupon it was closed by order of the Assembly. Clermont-Tonnerre was murdered by the populace during the rising of Aug. 9–10, 1792.

See *Recueil des opinions de Stanislas de Clermont-Tonnerre* (1791), the text of his speeches as published by himself; A. Aulard, *Les Orateurs de la Constituante* (1905).

CLERUCHY, a kind of colony of Athenian citizens planted in a conquered country. The settlers retained their status as citizens of Athens, and their allotments were politically part of Attic soil. These settlements were of three kinds: (1) where the inhabitants were extirpated and the settlers occupied the whole territory; (2) where the settlers occupied allotments in the midst of a conquered people; and (3) where the inhabitants gave up portions of land to settlers in return for certain pecuniary concessions. The primary object was unquestionably military, and

in the later days of the Delian League (*q.v.*) the system was a precaution against disaffection on the part of the allies.

A secondary object of the cleruchies was to provide a source of livelihood to the poorer Athenians. Plutarch suggests that Pericles by this means rid the city of mischievous loafers; but it would appear that the cleruchs were selected by lot, and a wise policy would not entrust important military duties to wastrels. In 50 years about 10,000 cleruchs went out, so that the reduction of the citizen population was considerable.

The cleruchs were liable to military service and to that taxation which fell upon Athenians at home. They were not liable for the tribute paid by members of the Delian League; this follows from their status as Athenian citizens. In internal government the cleruchs adopted the Boulê and Assembly system of Athens itself; so we read of Polemarchs, Archons *eponumoi*, *Agoranomoi*, *Strategoï*, in various places. With local self-government there was combined a certain central authority in jurisdiction; the more important cases, particularly those between a cleruch and a citizen at home, were tried before the Athenian dicasts.

BIBLIOGRAPHY.—See G. Gilbert, *Constitutional Antiquities of Athens and Sparta* (Eng. trans., 1895); A. H. J. Greenidge, *Handbook of Greek Constitutional Antiquities* (1896); L. Whibley, *Companion to Greek Studies* (1916); for the Periclean cleruchs, see PERICLES; DELIAN LEAGUE.

CLERVAUX (*clara vallis*), a town in the northern province of Oesling, grand-duchy of Luxembourg, on the Clerf, a tributary of the Sure. Pop. (1905) 866. The old castle of the Lannoy family still exists. In 1798 the people of Clervaux specially distinguished themselves against the French establishment of conscription. The survivors of this Kloppel-krieg ("cudgel war") were shot, and a fine monument commemorates them.

CLETUS, formerly regarded as an early successor of St. Peter in the see of Rome, or, according to Epiphanius and Rufinus, as directing the Roman Church with Linus during Peter's lifetime. He is now identified with Anencletus (*q.v.*). See Colombier, in *Rev. des questions hist.*, Ap. 1st, 1876, p. 413.

CLEVE (Clèves), a town of Germany in the Prussian Rhine province, formerly the capital of the duchy of its own name, 46 m. N.W. of Düsseldorf, 12 m. E. of Nijmegen, on the main Cologne-Amsterdam railway. Pop. (1925) 20,296.

The town was the seat of the counts of Cleve as early as the 11th century, but it did not receive municipal rights until 1242. The duchy of Cleve, which lay on both banks of the Rhine passed in 1368 to the counts of La Marck and was made a duchy in 1417, being united with the neighbouring duchies of Jülich and Berg in 1521. By the treaty of Xanten in 1614, Cleve passed to the elector of Brandenburg, being afterwards incorporated with the electorate by the elector, Frederick William. The part of the duchy on the left bank of the Rhine was ceded to France in 1795; the remaining portion in 1805. In 1815 it was restored to Prussia, except some small portions which were given to the kingdom of Holland. The town is built in the Dutch style, lying on three small hills in a fertile district near the frontier of Holland, about 2 m. from the Rhine, with which it is connected by a canal (the Spoykanal). The old castle of Schwanenburg is associated with the legend of the "Knights of the Swan," immortalized in Wagner's *Lohengrin*. The building has been restored in modern times to serve as a court of justice and a prison. The collegiate church (Stiftskirche) dates from about 1340. The Annexkirche, formerly a convent of the Minorites, dates from the middle of the 15th century. The chief manufactures are boots and shoes, tobacco and machinery; there is also some trade in cattle and in wine. There are mineral wells. Cleve has become a favourite summer resort.

CLEVEDON, watering-place, Somersetshire, England, on the Bristol Channel, 15½ m. W.S.W. of Bristol on a branch of the G.W.R. Pop. of urban district (1931) 7,033. The cruciform church of St. Andrew has Norman and later portions. Clevedon Court is a mediaeval mansion, dating originally from the 14th century, though much altered in the Elizabethan and other periods.

CLEVELAND, BARBARA VILLIERS, DUCHESS OF (1641–1709), mistress of the English king, Charles II., was the daughter of William Villiers, 2nd Viscount Grandison (d. 1643) by

his wife Mary (d. 1684), daughter of Paul, 1st Viscount Bayning. In April 1659 Barbara married Roger Palmer, who was created earl of Castlemaine two years later, and soon after this marriage her intimacy with Charles II. began. The king was probably the father of her first child, Anne, born in Feb. 1661, although the paternity was also attributed to one of her earliest lovers, Philip Stanhope, 2nd earl of Chesterfield (1633-1713). Mistress Palmer was made a lady of the bedchamber to Catherine of Braganza. Her house became a rendezvous for the enemies of Clarendon, and according to Pepys she exhibited a wild paroxysm of delight when she heard of the minister's fall from power in 1667. Her influence, which had been gradually rising, became supreme at court in 1667 owing to the marriage of Frances Stuart (la belle Stuart) (1648-1702) with Charles Stuart, 3rd duke of Richmond (1640-72). Accordingly, Louis XIV., instructed his ambassador to pay special attention to Lady Castlemaine, who had become a Roman Catholic in 1663.

In Aug. 1670 she was created countess of Southampton and duchess of Cleveland, with remainder to her first and third sons, Charles and George Palmer, the king at this time not admitting the paternity of her second son Henry. About 1670 her influence over Charles began to decline. She consoled herself meanwhile with other lovers, among them John Churchill, afterwards duke of Marlborough and William Wycherley; by 1674 she had been entirely supplanted at court by Louise de K rouaille, duchess of Portsmouth. The duchess of Cleveland then went to reside in Paris, where she formed an intrigue with the English ambassador, Ralph Montagu, afterwards duke of Montagu (d. 1709) who lost his position through some revelations which she made to the king. She returned to England just before Charles's death in 1685. In July 1705 her husband, the earl of Castlemaine, whom she had left in 1662, died; and in the same year the duchess was married to Robert (Beau) Feilding (d. 1712), a union which was declared void in 1707, as Feilding had a wife living. She died at Chiswick on Oct. 9, 1709.

Her eldest son, CHARLES FITZROY (1662-1730), was created in 1675 earl of Chichester and duke of Southampton, and became duke of Cleveland, and earl of Southampton on his mother's death. Her second son, Henry (1663-90), was created earl of Euston in 1672 and duke of Grafton in 1675; by his wife Isabella, daughter of Henry Bennet, earl of Arlington, he was the direct ancestor of the later dukes of Grafton; the most popular and the most able of the sons of Charles II., he met his death through a wound received at the storming of Cork. Her third son, George (1665-1716), was created duke of Northumberland in 1683 and died without issue. Her daughters were Anne (1661-1722), married in 1674 to Thomas Lennard, Lord Dacre (d. 1715), who was created earl of Sussex in 1684; Charlotte (1664-1718), married in 1677 to Edward Henry Lee, earl of Lichfield (d. 1716); and Barbara (1672-1737), the reputed daughter of John Churchill, who entered a nunnery in France, and became by James Douglas, afterwards 4th duke of Hamilton (1658-1712), the mother of an illegitimate son, Charles Hamilton (1691-1754).

See G. S. Steinmann, *Memoir of Barbara duchess of Cleveland* (1871) and *Addenda* (1874).

CLEVELAND (or CLEIVELAND), JOHN (1613-58), English poet and satirist, was born at Loughborough, and educated at Hinckley school under the Puritan, Richard Vines. At the age of 14 he entered Christ's college, Cambridge, and in 1634 was elected to a fellowship at St. John's. He opposed the candidature of Oliver Cromwell as M.P. for Cambridge, and on the triumph of the Puritan party removed (1643) to Oxford. His gifts as a satirist were already known and he was warmly received by the King, whom he followed (1645) to Newark. In that year he was formally deprived of his Cambridge fellowship as a "malignant." He was judge-advocate in the garrison at Newark, and under the governor defended the town until in 1646 Charles I. ordered the surrender of the place to Leslie.

His indignation when the Scots surrendered the King to the Parliament is expressed in "The Rebel Scot." Cleveland wandered over the country depending on the alms of the Royalists for bread, and in 1655 spent three months in Norwich gaol. He

was released early in 1656, and found his way eventually to Gray's Inn, where Aubrey says he and Samuel Butler had a "club" every night. There he died on April 29 1658.

Cleveland's poems were more highly esteemed than Milton's by his contemporaries, and his popularity is attested by the very numerous editions of his works. His poems are therefore of great value as an index to the taste of the 17th century. His verse is frequently obscure and full of the far-fetched conceits of the "metaphysical" poets; but the energy of his invective leaves no room for obscurity in such pieces as "Smectymnuus, or the Club Divines," "Rupertismus" and "The Rebel Scot." His poem "Or the Memory of Mr. Edward King," is included in the collection of verse which contained Milton's "Lycidas."

For a bibliographical account of Cleveland's poems see J. M. Berdan, *The Poems of John Cleveland* (New York, 1903), in which there is a table of the contents of 23 editions, of which the chief are: *The Character of a London Diurnal, with Several Select Poems* (1647); *Poems. By John Cleveland. With additions, never before printed* (1659); *J. Cleveland Revived . . .* (1659), in which the editor, E. Williamson, says he inserted poems by other authors, trusting to the critical faculty of the readers to distinguish Cleveland's work from the rest; *Cleavelandi Vindiciae . . .* (1677), edited by two of Cleveland's former pupils, Bishop Lake and S. Drake, who profess to take out the spurious pieces; and a careless compilation, *The Works of John Cleveland . . .* (1687), containing poems taken from all these sources.

CLEVELAND, STEPHEN GROVER (1837-1908), President of the United States from 1885 to 1889, and again from 1893 to 1897, was born, the fifth in a family of nine children, in Caldwell, Essex county, N.J., on March 18, 1837. His father, Richard F. Cleveland, a Presbyterian clergyman, was a descendant of Moses Cleveland, who emigrated from England to Massachusetts in 1635. The family removed to Fayetteville, N.Y., and afterwards to Clinton, N.Y. It was intended that young Grover should be educated at Hamilton college, but this was prevented by his father's death in 1852. After working several years he set out for Cleveland, O., but stopped near Buffalo, N.Y., to work for his uncle. In 1855 he became a clerk in a Buffalo law office and in 1859 was admitted to the bar. When the Civil War began, the three Cleveland brothers drew lots to see which should remain at home to support their mother; the lot fell to Grover, and when he was drafted he hired a substitute.

In 1863 he was appointed assistant district attorney of Erie county, of which Buffalo is the chief city. This was his first public office, and it came to him, as, apparently, all later preferences, without any solicitation of his own. Two years later (1865) he was the Democratic candidate for district attorney, but was defeated. In 1869 Cleveland was nominated by the Democratic Party for the office of sheriff, and, despite the fact that Erie county was normally Republican, was elected. The years immediately succeeding his retirement from the office of sheriff in 1873 he devoted to the practice of law, coming to be recognized as one of the leaders of the western New York bar. In the autumn of 1881 he was nominated by the Democrats for mayor of Buffalo. The city government had been characterized by extravagance and maladministration, and a revolt of the independent voters at the polls overcame the usual Republican majority and Cleveland was elected. As mayor he attracted wide attention by his independence and businesslike methods, and under his direction the various departments of the city government were thoroughly reorganized. His ability received further recognition when in 1882 he was nominated, by the strategy of his campaign managers, as candidate for governor. The Republican Party in the State was at that time weakened by quarrels within its ranks, and this advantage was greatly increased by the Republicans' nomination for governor of Charles J. Folger (1818-84), then secretary of the Treasury, about whose nomination the cry of Federal interference was raised as a result of the methods employed in securing his nomination. All this, together with the popularity of Cleveland, brought about Cleveland's election by the unprecedented plurality of 192,854. As governor, Cleveland's course was marked by the stern qualities he had displayed in his other public positions. The demands of party leaders were made subordinate to public interest. He promoted the passage of a good civil service law. All bills passed by the

legislature were subjected to the governor's laborious scrutiny, and the veto power was used without fear or favour.

In 1884 the Democratic Party had been out of power in national affairs for 23 years. In this year, however, the generally disorganized state of the Republican Party, weakened by the defection of a large group of Independents, known as "Mugwumps," gave the Democrats an unusual opportunity. Upon a platform which called for radical reforms in the administrative departments, the civil service and the national finances, Cleveland was nominated for president, despite the opposition of the Tammany delegation. The nominee of the Republican Party, James G. Blaine (*q.v.*), of Maine, had received the nomination only after a contest in which violent personal animosities were aroused. The campaign that followed was one of the bitterest political contests in American history. Cleveland was accused of favouring the South because he had avoided war service and his private life was attacked; on the other side Blaine was associated with certain political scandals in Washington. The result was close, but Cleveland carried New York and was elected by an electoral majority of 219 to 182.

Cleveland's first term was uneventful, but was marked by firmness, justice and steady adherence on his part to the principles which he deemed salutary to the nation. He was especially concerned in promoting a non-partisan civil service. He stood firmly by the "Pendleton bill" (1883), designed to classify the subordinate places in the service, and to make entrance and promotion depend upon competitive examination of applicants. It applied only to clerkships, but the president was authorized to add others to the classified service from time to time. He added 11,757 during his first term.

President Cleveland made large use of the veto power upon bills passed by Congress, vetoing or "pocketing" during his first term 413 bills, more than two-thirds of which were private pension bills. The most important bill vetoed was the Dependent Pension bill, a measure opening the door, by the vagueness of its terms, to frauds upon the Treasury. Many of these bills were supported by Democrats, and Cleveland's opposition further alienated party leaders. In 1887 there was a large and growing surplus in the Treasury. About two-thirds of the public revenue was derived from duties on imports, in the adjustment of which the doctrine of protection to native industry had a large place. Cleveland attacked the system with great vigour in his annual message of 1887. He did not propose the adoption of free trade, but the Administration tariff measure, known as the Mills bill, passed the House, and although withdrawn owing to amendments in the Republican Senate, it alarmed and exasperated the protected classes, among whom were many Democrats.

In the following year (1888), the Democrats renominated Cleveland, and the Republicans nominated Benjamin Harrison, of Indiana. The campaign turned on the tariff issue, and Harrison was elected, receiving 233 electoral votes to 168 for Cleveland who, however, received a popular plurality of more than 100,000. Cleveland then resumed the practice of law in New York.

Congress had passed a law in 1878 requiring the Treasury department to purchase a certain amount of silver bullion each month and coin it into silver dollars to be full legal tender, and no date was fixed for this operation to cease, both parties being in favour of this policy. Cleveland had written a letter for publication before he became president, saying that a financial crisis of great severity must result if this coinage were continued and expressing the hope that Congress would speedily put an end to it. In 1890 Congress, controlled by the Republican Party, passed the McKinley bill, by which the revenues of the Government were reduced by more than \$60,000,000 annually. At this same time expenditures were largely increased by liberal pension legislation, and the Government's purchase of silver bullion almost doubled by the provisions of the new Sherman Silver Purchase Act of 1890.

In 1892 Cleveland was nominated for president a third time in succession. President Harrison was nominated by the Republicans, who had lost strength due to the passage of the McKinley

bill. Cleveland received 277 electoral votes and Harrison 145, and 22 were cast for James B. Weaver, of Iowa, the candidate of the "People's" party. Cleveland's second term embraced some notable events. The most important was the repeal of the silver legislation. Nearly \$600,000,000 of "fiat money" had been thrust into the channels of commerce in addition to \$346,000,000 of legal tender notes that had been issued during the Civil War. A reserve of \$100,000,000 of gold had been accumulated for the protection of these notes. In April 1893 the reserve fell below this sum. President Cleveland called an extra session of Congress to repeal the silver law. The House promptly passed the repealing act. In the Senate there was a protracted struggle. The Democrats now had a majority of that body and they were more pro-silver than the Republicans. The president had undertaken to coerce his own party to do something against its will, and it was only by the aid of the Republican minority that the passage of the repealing bill was at last made possible (Oct. 30). The mischief, however, was not ended. The deficit in the Treasury made it inevitable that the gold reserve should be used to meet current expenses; holders of legal tender notes presented them for redemption; borrowing was resorted to by the Government; bonds were issued and sold to the amount of \$162,000,000; the business world was in a state of constant agitation; commercial distress was widespread; wages were reduced in many employments, accompanied by labour troubles. The centre of disturbance was the Pullman strike at Chicago, whence the disorder extended to the Pacific coast, causing riot and bloodshed in many places. After waiting a reasonable time, as he conceived, for Gov. Altgeld of Illinois to act, Cleveland, on July 6, 1894, despite Gov. Altgeld's protest, directed the military forces of the United States to clear the way for trains carrying the mails. The rioters in and around Chicago were dispersed in a single day, and within a week the strike was broken.

Another important event was the action of the Government regarding the question of arbitration between Great Britain and Venezuela (*q.v.*). On Dec. 17, 1895, President Cleveland sent to Congress a special message calling attention to Great Britain's action in regard to the disputed boundary line between British Guiana and Venezuela, and declaring the necessity of action by the United States to prevent an infringement of the Monroe Doctrine. Congress at once appropriated funds for an American commission to investigate the matter. The diplomatic situation became very acute for the moment. Negotiations with Great Britain ensued, and before the American commission finished its work Great Britain had agreed (Nov. 1896) to arbitrate on terms which safeguarded the national dignity on both sides.

Cleveland's independence and party difficulties were shown during his second term in his action in regard to the tariff legislation of his party in Congress. A tariff bill introduced in the House by William Lyne Wilson, of West Virginia, was so amended in the Senate through the instrumentality of Senator Arthur Pue Gorman and a coterie of anti-Administration Democratic senators that, although unwilling to veto it, the president signified his dissatisfaction with its too high rates by allowing it to become a law without his signature. He carried the fight with this group of senators to the Senate by letters in which he denounced their lack of support. Cleveland's second administration began by vigorous action in regard to Hawaii; he at once withdrew from the Senate the annexation treaty which President Harrison had negotiated, and started an attempt to restore the dethroned queen, Liliuokalani, but was not successful, owing to Hawaiian opposition.

During his second term Cleveland added no less than 44,004 places in the civil service to the classified list, bringing the whole number up to 86,932. Toward the end of this term the president became very much out of accord with his party on the free-silver question, in consequence of which the endorsement of the administration was withheld by the Democratic national convention at Chicago in 1896. In the ensuing campaign the president and his cabinet, with the exception of Hoke Smith (b. 1855), secretary of the interior, who resigned, gave their support to Palmer and Buckner, the national, or "Sound Money" Democratic nominees.

Cleveland's second term expired on March 4, 1897, and he then retired into private life, universally respected and constantly consulted, in the university town of Princeton, N.J., where he died on June 24, 1908. He was a trustee of Princeton university and Stafford Little lecturer on public affairs. Chosen in 1905 as a member of a committee of three to act as trustees of the majority of the stock of the Equitable Life Assurance Company, he promoted the reorganization and the mutualization of that company, and acted as rebate referee for it and for the Mutual and New York Life insurance companies. He published *Presidential Problems* (1904), made up in part of lectures at Princeton university, and *Fishing and Hunting Sketches* (1906).

BIBLIOGRAPHY.—R. E. McElroy's authorized biography of Cleveland, *Grover Cleveland, the Man and the Statesman* (1923), is a comprehensive work. W. O. Stoddard's *Grover Cleveland* (1888; "Lives of the Presidents" series), and J. L. Whittle's *Grover Cleveland* (1896; "Public Men of To-day" series), are judicious volumes; and "Campaign Biographies" (1884) were written by W. Dorsheimer, F. E. Goodrich, P. King and D. Welch; *Grover Cleveland, a Study in Political Courage* (1922) is interesting but perhaps too favourable, while the study of Cleveland by H. L. Stoddard in *As I Knew Them* (1927) takes a somewhat opposite view-point. A large amount of magazine literature has been devoted to President Cleveland's career. G. F. Parker had a series of articles in *The Saturday Evening Post* on Aug. 28, 1920, April 7, 1923, June 9, 1923, Nov. 10, 1923, March 29, 1924, under the titles "Grover Cleveland's Career in Buffalo," "Grover Cleveland's First Administration as President," "Grover Cleveland's Second Administration as President," "Grover Cleveland's Life in Princeton," and "Grover Cleveland's One Business Venture." See articles by Woodrow Wilson (*Atlantic Monthly*, vol. lxxix.: "Cleveland as President"); Carl Shurz (*McClure's Magazine*, vol. ix.: "Second Administration of Grover Cleveland"); William Allen White (*McClure's*, vol. xviii.: "Character Sketch of Cleveland"); Gamaliel Bradford (*Atlantic Monthly*, Nov. 1920: "Grover Cleveland"); Walter B. Stevens (*Missouri Historical Review*, Jan. 1927): "When Cleveland Came to St. Louis"; and Henry L. Nelson (*North American Review*, vol. clxxxviii.). Also Jesse L. Williams, *Mr. Cleveland: A Personal Impression* (1909); G. W. Parker, *Recollections of Grover Cleveland* (1909); C. H. Armitage, *Grover Cleveland as Buffalo Knew Him* (1927); G. C. Griffin, *Writings on American History* (1906-23).

CLEVELAND, a city and port of entry of the State of Ohio, U.S.A., and the county seat of Cuyahoga county, the fifth largest city in the United States. It is on Lake Erie, at the mouth of the Cuyahoga river, about 260m. N.E. of Cincinnati, 357m. E. of Chicago and 623m. W. of New York. Pop. (1920) 796,841, of whom 239,538 were foreign-born, 310,241 native-born but of foreign parentage (*i.e.*, having one or both parents foreign-born), and 34,451 negroes. Of the 239,538, foreign-born, Poles were predominant (35,024 or 14.6%), with the Hungarians (29,724, or 12.4%) and Germans (26,476, or 10%) next in importance. The population in 1930 was 900,429.

The city commands pleasant views from its position on a plateau, which, at places on bluffs along the shore, has elevations of about 75ft. above the lake level and rises gradually toward the south-east to 115ft., and on the extreme east border to more than 200ft. above the lake, or about 800ft. above sea-level; the surface has, however, been cut deeply by the Cuyahoga, which here pursues a meandering course through a valley about $\frac{1}{2}$ m. wide. The city's shore-line is 14.2m. long. The city occupies a total area (1925) of 69,154 sq.m., much the greater part of which is east of the river. The streets are of unusual width (varying from 60ft. to 132ft.) and paved chiefly with asphalt and brick. For its many well shaded streets, Cleveland became known as the "Forest city." The municipality maintains an efficient forestry department. About $\frac{1}{2}$ m. from the lake and the same distance east of the river is the public square, or Monumental park in the business centre of the city. Thence the principal thoroughfares radiate. The river valley is spanned by several viaducts, of which the most noteworthy is the High Level bridge, with central span of 591ft. in length and 96ft. above water. The total length, with approaches, is 5,630ft.; the cost, \$5,407,000. Lower Euclid avenue (the old country road to Euclid, O., and Erie, Pa.) is the centre of retail trade. This avenue, east of 12th street, was once bordered with handsome houses and spacious and beautifully-ornamented grounds, and was famous as one of the finest residential streets in the country. Many houses remain, but the residential

sections are elsewhere, in the suburban villages or cities of East Cleveland, Cleveland Heights, Shaker Heights and Lakewood. The building of the Union Terminal station has radically changed lower Superior avenue, once the retail commercial centre, for the south side from the public square westward has been vacated for buildings subsidiary to the railroad enterprises. In 1902 the city arranged for grouping its public buildings—in the so-called "Group Plan." The court-house and city hall are on the edge of the plateau overlooking Lake Erie; 1,000ft. S., on Superior avenue, are the Federal building and the public library. On the west side of 6th street, which leads to the city hall, and near the latter, is the public auditorium, with 12,500 seats, and with a Music Hall and Little Theatre with seating accommodation of 3,700. The "Group plan" called for a mall, 600 ft. wide, leading from the structures on the lake front to those on Superior. The city has, besides, numerous fine office buildings, including that of the Society for Savings (an institution in which each depositor is virtually a stock-holder), the Williamson, the National City, the Guardian, the Union Trust, the Engineers Bank, the Federal Reserve Bank and Hanna buildings; the Union Terminal building, with its tower 720ft. high, visible for many miles from the city; the Ohio Bell Telephone building, of the newer pyramidal type; the *Plain Dealer* newspaper building; the Cleveland Trust company's bank; the Museum of Art; Trinity cathedral (Episcopalian), the Church of the Covenant (Presbyterian), St. Agnes (Catholic), the Temple (Jewish), the Amasa Stone Memorial chapel (Adelbert college), the Allen Memorial Medical library. In the public square is a soldiers' and sailors' monument consisting of a granite shaft rising from a memorial room to a height of 125ft., and surmounted with a figure of Liberty; in the same park also, are a bronze statue of Moses Cleveland, the founder of the city, and a bronze statue of Tom L. Johnson, a notable mayor. On a commanding site in Lake View cemetery is the Garfield memorial (finished in 1890) in the form of a tower (165ft. high), designed by George Keller and built mostly of Ohio sandstone; in the base is a chapel containing a statue of Garfield, and several panels on which are portrayed various scenes in his life; his remains are in the crypt below the statue. A marble statue of Commodore Oliver H. Perry, erected in commemoration of his victory on Lake Erie in 1813, is in Gordon park. In Wade park are the Goethe-Schiller statue and a statue of Kosciuszko. Facing the University Circle is a statue (by Saint-Gaudens) of Marcus Alonzo Hanna (*q.v.*) the famous Republican statesman.

The 26 parks contain altogether more than 2,800ac., not including the airport of 904 acres. A chain of parks connected by drive-ways follows the picturesque valley of Doan Brook, on the east border of the city. At the mouth of the brook, and on the lake front, is the beautiful Gordon park of 122ac., formerly the private estate of William J. Gordon, but given by him to the city in 1893; from this extends up the Doan valley the large Rockefeller park, which was given to the city in 1896 by John D. Rockefeller and others, and which extends to and adjoins Wade park (85ac., given by J. H. Wade) in which is the Museum of Art. Monumental park is divided into four sections (containing about 1ac. each) by Superior avenue and Ontario street. Of the several cemeteries, Lake View (about 300ac.), on an elevated site on the east border, is by far the largest and most beautiful, its natural beauty having been enhanced by the landscape gardener. Besides Garfield, John Hay and Marcus A. Hanna are buried there.

Education.—Cleveland has an excellent public-school system. A general State law, enacted in 1904, placed the management of school affairs in the hands of an elective council of seven members, five chosen at large and two by districts. This board has power to appoint a school director and a superintendent of instruction. The superintendent appoints the teachers, the director all other employees; appointments are subject to confirmation by the board, and all employees are subject to removal by the executive officials alone. The plan of education minimizes routine, replacing traditional programmes by new curricula based upon a more scientific study of childhood and youth. Greater attention is also paid to the differing interests and capacities of groups of pupils. In 1927 there were 13 senior and 12 junior high-schools, and 114

schools for grades 1 to 6, in the city. The school budget of 1927-28 was \$19,904,674. Besides the public-school system there are many parochial schools; the university school, with an eight years' course; the Hathaway-Brown and the Laurel school for girls; the Western Reserve university, with its medical school (opened in 1843), the Franklin T. Backus Law school (1892), the dental department (1892), Adelbert college (until 1882 the Western Reserve college, founded in 1826 at Hudson, O.), the College for Women (1888), the Library school (1904), the School of Pharmacy (incorporated in 1886, affiliated in 1908), the School of Applied Social Sciences (1916), the School of Nursing (1923), the Graduate school (reorganized in 1926); the Case School of Applied Science, founded in 1880 by Leonard Case (1820-80) and opened in 1881; Cleveland college, a down-town branch of the university, under a separate board of trustees, and affiliated also with the Case School of Applied Science; the Cleveland School of Art; John Carroll university, formerly St. Ignatius college (conducted by the Fathers of the Society of Jesus; incorporated 1890), which has an excellent meteorological observatory. In 1926-27 Western Reserve university had 558 instructors and 3,177 students, not including extension courses or the summer session (902 in Adelbert college; 899 in College for Women; 304 in graduate department; and 224 in medical, 269 in law, 203 in dental and 78 in library school); and the Case School of Applied Science 64 instructors and 568 students. Important educational work is carried on by the Museum of Art, through classes, lectures and special exhibitions. Another valuable influence has been the Museum of Natural History opened in 1922. The musical development of the city has been stimulated by the creation of a symphony orchestra and the organization of a school of music. The public library contained over 1,000,000 vol. in 1928, the Case library (subscription), 110,000 vol., the Hatch library of Adelbert college about 130,000, the library of the College for Women 26,000, the Cleveland Medical library 35,000, the library of the Western Reserve Historical Society over 150,000 and the Cleveland Law library, in the court-house, 50,000 volumes.

The city has a highly developed system of charitable and corrective institutions. A farm of more than 1,600 ac., the Cleveland Farm Colony, 11 m. from the city, takes the place of workhouses, and has many cottages in which live those of the city's poor who were formerly classed as paupers and were sent to poorhouses, and who now apply their labour to the farm and are relieved from the stigma that generally attaches to inmates of poorhouses. On the "farm" the city maintains an "infirmary village," a tuberculosis sanatorium, a detention hospital, a convalescent hospital and houses of correction. On a farm 22 m. from the city is the Boys' Home (maintained in connection with the juvenile court) for "incorrigible" boys. The "cottage" plan has been adopted; each cottage is presided over by a man and wife whom the boys call father and mother. At an equal distance from the city but further west is a Girls' home, similarly administered. Besides the city hospital there are the Northern Ohio (for the insane, founded in 1855), Lakeside, St. Alexis, the Charity (the last managed by sisters of charity), Mount Sinai, St. Luke's, St. John's, Lutheran, Huron road and Maternity hospitals, and the Babies dispensary and hospital. A medical centre was begun through the grouping of the new buildings of the School of Medicine, built at a cost of \$2,500,000, the Maternity hospital and Babies dispensary and hospital. To these were to be added the Lakeside hospital (removed from its down-town site), and its subsidiary buildings, for which a fund of over \$8,000,000 was raised in 1927. A pathological institute has also been added, its cost borne by the general education board. The Goodrich House (1897), the Hiram House and Alta House are among the best equipped and most efficient social settlements in the country. Cleveland has also its orphan asylums, homes for the aged, homes for incurables and day nurseries, besides a home for sailors, homes for young working women and retreats for unfortunate girls. The many charitable organizations, Protestant and Catholic, are united in a Welfare Federation. There is also a Federation of Jewish Charities. Their support comes from endowment funds and from the Community Fund, created in 1919. The money for this fund

is collected in annual "drives," the proceeds of which averaged each year for the first nine years \$4,250,000. The principal newspapers of the city are the *Plain Dealer* (1841, independent), which in 1917 acquired the *Leader* (1847, Republican); the *Press* (1878, independent); and the *News* (1889, Republican). Bohemian, Hungarian and German dailies are published.

Municipal Enterprise.—Municipal ownership was a prominent issue in Cleveland during the mayoralty of Tom Loftin Johnson (1854-1911), a street railway owner, iron manufacturer, an ardent single-taxer, who was elected in 1901, and re-elected in 1903, 1905 and 1907. The struggle opened with the organization of a new street car company which began operations on Nov. 1, 1906, charging a 3 cent fare. The grants to this company were owned by the Forest City Railway company and the property was leased to the Municipal Traction Company (on behalf of the public—the city itself not being empowered to own and operate street railways). In 1908 the Cleveland Electric Street Railway Corporation (capital \$23,000,000), which owned most of the electric lines in the city, was forced to lease its property to the municipality's holding company, receiving a "security franchise," providing that under certain circumstances (e.g., if the holding company should default in its payment of interest) the property was to revert to the corporation, which was then to charge not more than 25 cents for six tickets. In Oct. 1908, at a special election, the security franchise was invalidated, and the entire railway system was put in the hands of receivers. In 1909 Johnson was defeated. In 1910 the Cleveland Railway company received a 25 year franchise, embodying the "Tayler" plan, named after the Federal judge under whose authority the receivership was administered. This called for a service at cost and gave the city council important rights of control. The railway company was entitled to a return on its capital stock of 6%, and the rate of fare became dependent upon receipts from traffic. For a time the fare was 3 cents and a cent for transfers, but when the years of rapidly mounting costs of service came, the fare was necessarily raised. The franchise was amended in 1926, providing for a 7 cent fare, with a possible maximum of 10 cents. Its life was extended until 1951. The municipality owns the waterworks, a small electric-light plant, the garbage plant and bath houses. The city water is pumped to reservoirs from two intakes situated a distance of 4½ m. from the shore. The system has a delivery capacity of 300,000,000 gal. daily. The department served (1926) about 1,200,000 consumers. All water is metered and sells for 60 cents per 1,000 cu. feet. The two filtration plants, for the eastern and western sections of the city, have a total capacity of 315,000,000 gallons. The municipal electric-lighting plant does not seriously compete with the private lighting company. The municipal garbage plant (destructor) collects and reduces to fertilizer 400 tons of garbage per day.

Commerce.—To meet the demands of the rapidly increasing commerce the harbour has been steadily improved. In 1908 it consisted of two distinct parts, the outer harbour being the work of the Federal Government, and the inner harbour being under the control of the city. The outer harbour was formed by two breakwaters enclosing an area of 5 m. long and 1,600 to 3,800 ft. wide; the main entrance, 700 ft. wide, lying opposite the mouth of the Cuyahoga river; the depth of the harbour ranges from 19 to 23 feet. The inner harbour comprises the Cuyahoga, the old river-bed and connecting slips. The channel at the mouth of the river (32½ ft. wide) is lined on the west side by a concrete jetty 1,440 ft. long, and on the east side by commercial docks 1,602 ft. long. The river and the old river-bed furnish about 13 m. of safe dock frontage, the channel having been dredged for 6 m. to a depth of 19 feet.

Cleveland's rapid growth, both as a commercial and as a manufacturing city, is due largely to its situation between the iron regions of Lake Superior and the coal and oil regions of Pennsylvania and Ohio. Cleveland is a great railway centre and is one of the most important ports on the Great Lakes. The city is served by the New York Central, the New York, Chicago and St. Louis, the Pennsylvania, the Erie, the Baltimore and Ohio, and the Wheeling and Lake Erie railways and by steamboats to the prin-

principal ports on the Great Lakes. Cleveland is the largest ore market in the world, and its huge ore docks are among its most interesting features; the annual receipts and shipments of coal and iron ore are enormous. It also handles large quantities of lumber and grain. The most important manufactures are iron and steel, automobiles, electrical supplies, bridges, boilers, engines, car wheels, telescopes, sewing machines, printing presses, agricultural implements and various other commodities made wholly or chiefly from iron and steel. The value of automobiles manufactured in 1925 was \$123,555,673. More steel wire, wire nails, and bolts and nuts are made here than in any other city in the world (the total value for iron and steel products as classified by the census was, in 1925, \$107,771,912, and the value of foundry and machine-shop products in the same year was \$66,538,331), and more merchant vessels are built here than in any other American city. Cleveland makes much clothing (1925, \$48,251,242), and is the site of one of the largest refineries of the Standard Oil group. The output of Cleveland slaughtering and meat-packing houses in 1925 was valued at \$40,438,986. The total value of factory products in 1925 was \$1,094,785,000, an increase of 300% since 1914.

Government.—Since Cleveland became a city in 1836 it has undergone several important changes in government. The charter of that year placed the balance of power in a council composed of three members chosen from each ward and as many aldermen as there were wards, elected on a general ticket. From 1852 to 1891 the city was governed under general laws of the State which entrusted the more important powers to several administrative boards. Then, from 1891 to 1903, by what was practically a new charter, that which is known as the Federal plan of government was tried; this centred power in the mayor by making him almost the only elective officer, by giving to him the appointment of his cabinet of directors—one for the head of each of the six municipal departments—and to each director the appointment of his subordinates. The Federal plan was abandoned in 1903, a new municipal code coming into effect, which was in operation until 1909, when the Paine law established a board of control, under a Government resembling the old Federal plan. (For laws of 1903 and 1909 see OHIO.) In accordance with the authority conferred by the home rule amendment of the State Constitution, a charter, submitted by a special commission, was accepted by the citizens on July 1, 1913. This reduced the number of elected officers to the mayor and 25 councillors. By an amended charter, which took effect on Jan. 1, 1924, a manager system was introduced. The council of 25 members is chosen by districts, four in number, instead of by wards. The president of the council is called the mayor, but full administrative authority, with the duty of choosing heads of departments, is entrusted to the manager, elected by the council. Subordinate officials are appointed according to the merit system. Few if any cities in the Union have, in recent years, been better governed than Cleveland, and this seems to be due largely to the keen interest in municipal affairs which has been shown by her citizens. Especially has this been manifested by the Cleveland Chamber of Commerce and the Citizens' League, an organization of influential professional and business men, which, by issuing bulletins concerning candidates at the primaries and at election time, has done much for the betterment of local politics. The Cleveland Chamber of Commerce, an organization of 1,622 leading business men, is a power for good in the city; besides its constant and aggressive work in promoting the commercial interests of the city, it was largely influential in the Federal reform of the consular service; it studied the question of overcrowded tenements and secured the passage of a new tenement law with important sanitary provisions and fixed minimum air space; it urges and promotes home gardening, public baths, play-grounds, lunch-rooms, etc., for employees in factories; and it was largely instrumental in devising and carrying out the so-called "Group Plan" described above.

History.—A trading post was established at the mouth of the Cuyahoga river as early as 1786, but the place was not permanently settled until 1796, when it was laid out as a town by Moses Cleveland (1754–1806), who was then acting as the agent of the Connecticut Land company, which in the year before had pur-

chased from the State of Connecticut a large portion of the Western Reserve. In 1800 the entire Western Reserve was erected into the county of Trumbull and a township government was given to Cleveland; ten years later Cleveland was made the seat of government of the new county of Cuyahoga, and in 1814 it was incorporated as a village. Cleveland's growth was, however, very slow until the opening of the Ohio canal as far as Akron, in 1827; about the same time the improvement of the harbour was begun, and by 1832 the canal was opened to the Ohio river. Cleveland was thus connected with the interior of the State, for whose mineral and agricultural products it became the lake outlet. The discovery of iron ore in the Lake Superior region made Cleveland the natural meeting-point of the iron ore and the coal from the Ohio, Pennsylvania and West Virginia mines; and the city's great commercial importance dates from this time. The building of railways during the decade 1850–60 increased this importance, and the city grew with great rapidity. The growth during the Civil War was partly due to the rapid development of the manufacturing interests of the city, which supplied large quantities of iron products and clothing to the Federal Government. The population of 1,076 in 1830 increased to 6,071 in 1840, 17,034 in 1850, 43,417 in 1860, 92,829 in 1870, and to 160,146 in 1880. Until 1853 the city was confined to the east side of the river, but in that year Ohio City, which was founded in 1807, later incorporated as the village of Brooklyn, and in 1836 chartered as a city (under the name Ohio City), was annexed. Other annexations followed: East Cleveland (a district east of the present 55th street, and not the suburban city of that name) in 1872, Newburg in 1873, West Cleveland and Brooklyn in 1893, Glenville and South Brooklyn in 1905, Collinwood in 1910 and West Park in 1923. In recent history the most notable events not mentioned elsewhere in this article were the elaborate celebration of the centennial of the city in 1896, the happy solution of the street railway problem and the successful development of co-operation in charitable work through federation of organizations and annual contributions to the Community Fund.

CLEVELAND, a city of southern Tennessee, U.S.A., 29m. E.N.E. of Chattanooga, on Federal highway 11 and the Southern railway; the county seat of Bradley county. It has an air-port, Emmett Field. The population in 1920 was 6,522, and in 1930 was 9,136 by the Federal census. There are manganese mines near by, and the city has over 30 factories, employing 3,000 persons and producing goods valued at \$9,000,000 annually. During the Civil War Grant and Sherman for a time had headquarters here, in houses that are still standing. The battle of Ft. Hill was fought on the site of what is now Ft. Hill cemetery. Cleveland was settled about 1832 and was incorporated as a city in 1837. It was named after Col. Benjamin Cleveland, a commander at the battle of King's Mountain.

CLEVELAND HEIGHTS, a city of Cuyahoga county, Ohio, U.S.A., adjoining Cleveland on the east. It is a residential suburb, with a population of 2,955 in 1910, 15,236 in 1920, in 1930, 50,945 Federal census. It has a commission-manager form of government. The village was incorporated in 1903 and in 1922 it became a city.

CLEVER, an adjective implying dexterous activity of mind or body, and ability to meet emergencies with readiness and adroitness. The etymology and the early history of the word are obscure. Some derive it, in the sense of "quick to seize," from M.E. *cliver* or *clivre*, a claw. This original sense probably survives in the frequent use of the word for nimble, dexterous, quick and skilful in the use of the hands, and so it is often applied to a

horse, "clever at his fences." The word has also been connected with O.E. *gléaw*, wise, which became in M.E. *gleu*, and is cognate with Scottish *gleg*, quick of eye.

CLEYNARTS (CLENARDUS or CLÉNARD), **NICOLAS** (1495-1542), Belgian grammarian and traveller, was born at Diest, Brabant, on Dec. 5, 1495. Educated at the University of Louvain, he became a professor of Latin, which he taught by a conversational method. His *Institutiones in linguam graecam* (1530), and *Meditationes graecanicae* (1531) passed through a number of editions, and had many commentators. He maintained that the learner should not be puzzled by elaborate rules until he has obtained a working acquaintance with the language. In pursuit of a scheme for proselytism among the Arabs he travelled in 1532 to Spain, and tried in vain to gain access to the Arabic mss. in the possession of the Inquisition. Finally, in 1540, he set out for Africa to seek information for himself. He reached Fez, then a flourishing seat of Arab learning, but after 15 months of privation and suffering was obliged to return to Granada, and died in the autumn of 1542. He was buried in the Alhambra palace.

See his Latin letters to his friends in Belgium, *Nicolai Clenardi, Peregrinationum ac de rebus machometicis epistolae elegantissimae* (Louvain, 1550), and a more complete edition, *Nic. Clenardi Epistolarum libri duo* (Antwerp, 1561); also Victor Chauvin and Alphonse Roersch, "Étude sur la vie et les travaux de Nicolas Clénard" in *Mémoires couronnés* (vol. ix., 1900-01) of the Royal Academy of Belgium, which contains an extensive bibliography.

CLICHÉ. In the process of stereotype printing a matrix or mould is made in papier-mâché from the set type, and a solid casting is produced from this mould, which thus bears a surface of letters cast in relief, from which the actual prints are taken. The papier-mâché mould is called a cliché.

This term, representing as it does a mould for mechanical reproduction, has passed into use as an effective name for any hackneyed term or phrase. The cliché is the vice of the writer who trades in second-hand thought and expression; for him the sea becomes "the rolling wave," fire "the devouring element," and the sun "the orb of day."

CLICHTOVE, JOSSE VAN (d. 1543), Belgian theologian, educated at Louvain and Paris, became librarian of the Sorbonne. In 1519 he was elected bishop of Tournai, and in 1521 was translated to the see of Chartres. He is known as an antagonist of Luther. When Cardinal Duprat convened his Synod of Paris in 1528 to discuss the new religion, Clichtove was charged to collect and summarize the objections to the Lutheran doctrine. This he did in his *Compendium veritatum . . . contra erroneas Lutheranorum assertiones* (Paris, 1529). He died at Chartres on Sept. 22, 1543.

CLICHY, a manufacturing suburb of Paris. Pop. (1926) 50,039. It was, under the name of *Clippiacum*, a residence of the Merovingian kings. The church dates from the 17th century. The industries include the manufacture of starch, rubber, oil and grease, glass, chemicals and soap.

CLICKS, peculiar sounds of unknown origin, found in many languages. The German term *Schnalze* and the Afrikaans *klukken* are both attempts to give a descriptive name, but the English word *Click* is as onomatopoeic as any. The outstanding examples of click-speech are the Hottentot languages (Nama, !kora, Griqua, etc.) with four or five different clicks and those of the Bushmen of South Africa (!kung, kham, lai, etc.), with as many as nine different clicks. From contiguity with the Hottentots and Bushmen several Bantu stocks have acquired clicks, which are alien to Bantu speech-systems. Such stocks are the Zulus and Kaffirs while the Damaras, (originally Bantu), have dropped their language entirely and speak only Hottentot. In the interior, Afrikaans (Cape Dutch), has even acquired clicks.

It seems fairly well established now, that clicks are by no means confined to these South African tongues. There are cases of their presence in the Melanesian languages of the Eastern Pacific, the Q of Codrington and Paterson representing a click-sound. Clicks never appear very far north of the equator and a definite "click-zone" can be found girdling the earth with, and south of, the equator. A recent study of the Quichua language of

the Incas of Peru shows the existence of click-sounds, later rubbed down to simple gutturals, in the ancient tongue. The Aztec or Nahuatl tongue also had clicks and in the surviving Aztec spoken by Mexicans in the hills of the interior, the *tl*, final and initial, sounds exactly like a Hottentot dental click.

In the Nama speech (*q.v.*) (Standard Hottentot), there are four clicks, represented thus:

| | Tindall | German system | International Phonetic Association |
|----------------|---------|---------------|------------------------------------|
| Dental . . . | c | / | ǀ |
| Cerebral . . . | q | ! | ǂ |
| Palatal . . . | v | # | ǃ |
| Lateral . . . | x | // | Ǆ |

In the Bushman languages (so far as classified, 16 in number) other clicks exist having such signs as:

Guttural ǁ Semi-labial ǁ Labial ǃ

The sounds must be heard; no description can do more than convey a general idea of their nature. The dental click, for example, is pronounced by pressing the flattened tip of the tongue against the front teeth at the gums and quickly withdrawing it. Early attempts to define and describe these sounds will be found in the works mentioned below.

See H. Tindall, *A Grammar of the Namaqua-Hottentot Language* (Cape Town, n.d.); J. L. Döhne, *Zulu-Kafir Dictionary* (Cape Town, 1857); Meinhof, *Lehrbuch der Namasprache* (1909); Leonhard, *Aus Namaland und Kalahari* (1905); N. Whyment, *The Zone of Clicks* (Tokyo, 1923). CLIFF-DWELLERS. Once believed to be a mysterious vanished race, the inhabitants of the cliff-dwellings in the southwestern United States are now recognized as but Pueblo Indians of the prehistoric period characterized by black-on-white pottery; who, when under hostile pressure, lodged their homes and granaries on ledges under overhanging cliffs, where such were available; in other cases excavated horizontally into bluff faces, or built on steep-walled mesas. Their skeletal remains, artifacts, and masonry are identical with those of the same period found in ruins in canyon bottoms and valleys. The romantically inaccessible situation of the cliff ruins, however, is impressive. Among the best known are Cliff Palace and Spruce Tree House in Mesa Verde National Park, Colorado, and a series in Canyon de Chelly, Arizona.

See Nordenskiöld, *Cliff Dwellings of the Mesa Verde* (1893).

CLIFF-DWELLINGS, the general archaeological term for the habitations of certain primitive peoples, formed by utilizing natural recesses or shallow caverns in the faces of cliffs, sometimes with more or less modification to adapt them to the requirements of the buildings. They are to be distinguished from cave-dwellings, which, not necessarily high in cliff walls, usually were or are occupied in their natural state; and from rock-shelters, used for temporary shelter, for storage, as lookouts, and sometimes for sacrificial deposits and for burial of the dead. Dry caves have been used as habitations in all parts of the world, some of those in France and Spain dating from the earliest periods of human history. Caves are still inhabited in Tunis and in Central Africa, and as winter habitations by the Tarahumare and other Piman tribes of northern Mexico, who have modified the natural recesses by the addition of masonry windbreaks, storage-bins, etc. A class of cave-dwellers known as Basket-makers, of a culture older than that of the cliff-dwellers, lived in Utah, Colorado, Arizona and New Mexico; and another culture, known as Bluff-dwellers, occupied caves in the Ozark mountains of western Missouri-Arkansas. Other caves, such as Mammoth and Salts caves in Kentucky and Lovelock cave in Nevada, have yielded important artifacts of their primitive occupants.

Eskimo of King island in Bering strait, Alaska, as late at least as 1881, occupied winter houses made by excavating the loose granite rocks to form niches in a steep slope and by walling up the front and sides with stones placed over a driftwood framework, access being had by a long covered passage leading to an

CLIFF DWELLINGS OF THE SOUTH-WESTERN UNITED STATES

1. Spruce Tree House, Mesa Verde National park, south-western Colorado, one of the largest Mesa Verde structures (216 feet long and 89 feet wide, containing 114 rooms and 8 kivas or assembly rooms). It is three storeys high in its loftiest part, and its chambers are round, rectangular or triangular to adapt themselves to the limited ground space which the dwelling occupies.
2. The westerly edge of the Betáakín ruins, in the Navaho National Monument, in Arizona. These ancient stone houses are built more than a hundred feet above the canyon floor. Cliff-dwellings of this type extend over a wide area from southern Colorado as far south as the central part of Mexico.
3. Cliff Palace, Mesa Verde National park. Among the Mesa Verde ruins have been found pottery remains;

yucca sandals; woven cotton cloth; indications of reservoirs for irrigating; stone and bone implements; graves containing flexed skeletons; mummies; evidences of turkey domestication; and other mementos of the lives of the cliff-dwellers.

4. Montezuma Castle, in Arizona. This cliff-dwelling, although distant from Mesa Verde, is similar to it, even in small details of construction.

5. Cavate lodges of Puye, New Mexico, a type of cliff-dwelling consisting of communicating rooms excavated in the soft volcanic tuff of the cliffside, with terraced, flat-roofed houses built in front. These occur also along the Rio Verde in Arizona.

opening in the floor. Ancient cliff-dwellings are found in the States of Chihuahua and Jalisco, Mexico, and especially in Colorado, Utah, Arizona and New Mexico, those in the Mesa Verde National park in southwestern Colorado being noted for the excellence of their architecture. It was once believed that the cliff-dwellers of southwestern United States were of a pre-Indian pygmy race, but archaeological study has shown the structures and the objects found in them to be unquestionably of Pueblo origin, contemporaneous with numerous mesa-top and valley ruins, the selection of their sites, made accessible only by hand-and-toe holes pecked in the cliff, having been due to hostile pressure. In the Mesa Verde canyons the largest and most noted cliff-dwellings are: Cliff Palace, consisting of about 150 secular rooms and 23 kivas or ceremonial chambers, together with various square and circular towers, all built in a very compact group and following the curving face of the recess for about 300 feet. Spruce-tree house, 216 ft. long and 89 ft. wide (114 rooms and 8 kivas), was three storeys high in its loftiest part; its chambers were built round, rectangular, or triangular according to the exigencies of the limited ground space. Balcony house (25 rooms) is named from a wide shelf extending along the front of two of the houses and is built on the projecting floorbeams. There are many other similar dwellings in the Mesa Verde canyons, some of which have been excavated; and on the summit of the mesa are massive related pueblo-like structures, used perhaps chiefly for ceremonial purposes, as well as many pit-houses. Other important cliff-dwellings of Arizona are Casa Blanca in Canyon de Chelly, Montezuma castle on Beaver creek of Verde river, and various examples (e.g., Betáakin, Kitsil), in the Navaho National monument. Cliff-dwellings of this class extend from southern Colorado to central Mexico. Another type, known as cavate lodges, consists of groups of a few communicating rooms excavated in the friable volcano tuff of the cliffs, in front of which terraced houses of masonry with flat roofs were built. This class is common to the Puye and Rito de los Frijoles areas in northern New Mexico, and occurs also on the Rio Verde in Arizona.

CLIFFORD, the name of a famous English family and barony, taken from the village of Clifford in Herefordshire.

ROBERT DE CLIFFORD (c. 1275-1314), one of the most powerful barons of his age, won great renown at the siege of Carlarverock Castle in 1300, and after taking part in the movement against Edward II.'s favourite, Piers Gaveston, was killed at Bannockburn. His son Roger, 2nd baron (1299-1322), shared in the rebellion of Thomas, earl of Lancaster, and was probably executed at York on March 23, 1322.

JOHN, the 9th baron (c. 1435-1461) earned the name of the "butcher," in the Wars of the Roses, in which he fought for Henry VI.; after the battle of Wakefield in 1460 he murdered Edmund, earl of Rutland, son of Richard duke of York. Shakespeare refers to this incident in King Henry VI., and also represents Clifford as taking part in the murder of York, though it is practically certain that York was slain in the battle. Clifford was killed at Ferrybridge on March 28, 1461, and was afterwards

attainted. His young son Henry, the 10th baron (c. 1454-1523), lived disguised as a shepherd for some years, hence he is sometimes called the "shepherd lord." On the accession of Henry VII. the attainder was reversed and he received his father's estate. He fought at Flodden in 1513, and died on April 23, 1523. He is the subject of two of Wordsworth's poems, "The White Doe of Rylstone" and the "Song at the Feast of Brougham Castle." Henry, the 11th baron, was created earl of Cumberland in 1523, and from this time until the extinction of the title in 1643 the main line of Cliffords was associated with this earldom (q.v.).

On the death of George, 3rd earl of Cumberland, in 1605, the barony of Clifford, separated from the earldom, was claimed by his daughter Anne, countess of Dorset, Pembroke and Montgomery; and in 1628 a new barony of Clifford was created in favour of Henry, afterwards 5th and last earl of Cumberland. After Anne's death in 1676 the claim to the older barony passed to her daughter Margaret (d. 1676), wife of John Tufton, 2nd earl of Thanet, and her descendants, whose title was definitely recognized in 1691. After the Tuftons the barony was held with intervening abeyances by the Southwells and the Russells, and to this latter family the present Lord De Clifford belongs.

When the last earl of Cumberland died in 1643 the newer barony of Clifford passed to his daughter Elizabeth, wife of Richard Boyle, 2nd earl of Cork, and from the Boyles it passed to the Cavendishes, falling into abeyance on the death of William Cavendish, 6th duke of Devonshire, in 1858.

The barony of Clifford of Lanesborough was held by the Boyles from 1644 to 1753, and the Devonshire branch of the family still holds the barony of Clifford of Chudleigh, created in 1672.

See G. E. C. (okayne), *Complete Peerage*, vol. iii. new ed. (1913); and T. D. Whitaker, *History of Craven*, 3rd ed. (1878).

CLIFFORD OF CHUDLEIGH, THOMAS CLIFFORD, 1ST BARON (1630-1673), English lord treasurer, the son of Hugh Clifford of Ugbrook, near Exeter, was born on Aug. 1, 1630, matriculated at Exeter college in 1647, and entered the Middle Temple in 1648. He represented Totnes in the convention parliament of 1660 and in the parliament of 1661, and became a steady supporter of Arlington, in opposition to the chancellor, Clarendon. On the outbreak of the Dutch war in 1664 Clifford was appointed commissioner for the care of the sick and of prisoners; afterwards knighted and appointed ambassador to northern Europe, he served with the fleet in 1665 and 1666, and in Oct. 1667 was one of those selected by the Commons to prepare papers concerning the naval operations. In the same year he was made controller of the household, a privy councillor and a commissioner for the treasury and in 1668 treasurer of the household.

Clifford was an ardent Roman Catholic, a supporter of the royal prerogative, and of the French alliance as a means of forcing Romanism and absolute government on the country. As one of the Cabal ministry, therefore, he co-operated zealously with the king in breaking through the Triple Alliance and in effecting an understanding with France. He was the only minister, besides Arlington, entrusted with the secret treaty of Dover of 1670, which he signed as well as the ostensible treaty shown to all the members of the Cabal. In 1672, during the absence of Arlington and Coventry abroad, Clifford acted as principal secretary of state, and was chiefly responsible for the "stop of the exchequer" and probably also for the attack upon the Dutch Smyrna fleet. He was appointed that year a commissioner to enquire into the settlement of Ireland. On April 22 he was raised to the peerage, and on Nov. 28, by the duke of York's interest, was made lord treasurer. This excited the jealousy of Arlington, who had always aspired to that office, and he helped to secure Clifford's downfall by his support of the Test Act of 1673. On the passing of the bill Clifford, as a Roman Catholic, followed the duke of York into retirement. His resignation caused considerable astonishment, since he had never publicly professed his religion, and in 1671 had even built a new Protestant chapel at his home at Ugbrook. According to Evelyn, however, his conduct was governed by a promise previously given to James. He gave up the treasuryship and his seat in the privy council in June. On

July 3, 1673, he received a general pardon from the king. In August he said a last farewell to Evelyn, and in less than a month he died at Ugbrook. In Evelyn's opinion the cause of death was suicide, but his suspicions do not appear to have received any contemporary support. Clifford was one of the worst advisers of Charles II., but a sincere and consistent one. Evelyn declares him "a valiant, uncorrupt gentleman, ambitious, not covetous, generous, passionate, a most constant, sincere friend." He married Elizabeth, daughter of William Martin of Lindridge, Devonshire, by whom he had 15 children, four sons and seven daughters surviving him. He was succeeded as 2nd baron by Hugh, his fifth, but eldest surviving son.

See *Cambridge Modern History*, vol. v. (1908).

CLIFFORD, SIR HUGH, G.C.M.G.; G.B.E. (1866–), British colonial governor, son of Maj.-Gen. Sir H. H. Clifford, V.C., K.C.M.G., was born in London on March 5, 1866, and was educated at Woburn Park. In 1883 Clifford passed into the Malay States Civil Service, and, after executing a special mission towards the sultan of Pahang in 1887, became the governor's agent there. After filling several other administrative posts, he returned to Pahang as British resident during the years 1896–99. Four years later he became colonial secretary at Trinidad, and was transferred in the same capacity to Ceylon in 1907, where he remained until his appointment as governor of the Gold Coast in 1912. He was appointed governor of Nigeria in 1919 and, in 1925, governor of Ceylon. Apart from his distinguished career in the colonial service, Sir Hugh Clifford has made his name as a writer of distinction, his stories of the Malay Peninsula being among the best of his works of fiction. He married as his second wife the novelist, Mrs. Henry de la Pasture. Among his numerous works may be mentioned the following: *Studies in Brown Humanity* (1898); *Bush-Whacking* (1901); *Malayan Monochromes* (1913) and *The Further Side of Silence* (1916). Sir Hugh has also compiled with Sir Frank Swettenham a *Dictionary of the Malay Language* and contributed to this edition of the *Encyclopædia Britannica*.

CLIFFORD, JOHN (1836–1923), British Nonconformist minister and politician, son of a warp-machinist at Sawley, Derbyshire, was born on Oct. 16, 1836. He worked in a lace factory where he attracted the notice of Baptists, who sent him to the academy at Leicester and the Baptist college at Nottingham to be educated for the ministry. In 1858 he was called to Praed Street chapel, Paddington (London), and while officiating there he attended University college and pursued his education at the British Museum. He took his B.A. (1861), B.Sc. (1862), M.A. (1864), and LL.B. (1866), and in 1883 he was given an honorary D.D. by Bates college, U.S.A. At Praed Street chapel he obtained a large following, and in 1877 Westbourne Park chapel was opened for him. As a preacher, writer, propagandist, and ardent Liberal politician he became a power in the Nonconformist body. He was president of the London Baptist Association in 1879, of the Baptist Union in 1888 and 1899, and of the National Council of Evangelical Churches in 1898. His prominence in politics dates from 1903, in consequence of his advocacy of "passive resistance" by non-payment of taxes to the Education Act of 1902. Into this movement he threw himself with militant ardour, his own goods being distrained upon, with those of numerous other Nonconformists. The "passive resistance" movement, with Dr. Clifford as its chief leader, contributed to the defeat of the Unionist Government in Jan. 1906, and his efforts were then directed to getting a new act passed which should be undenominational. The rejection of Mr. Birrell's bill in 1906 by the House of Lords led Dr. Clifford and his followers to denounce the House of Lords, but as year by year went by, up to 1909, with nothing but failure on the part of the Liberal ministry to solve the education problem—failure due not to the House of Lords but to the inherent difficulties of the subject—"passive resistance" lost its interest. Dr. Clifford received a C.B. in 1921, and died on Nov. 20, 1923.

His chief writings are *The English Baptists* (1881); *The Christian Certainties*, 2nd ed. (1904); *The Ultimate Problems of Christianity* (1906). See C. T. Bateman: *John Clifford* (1904); D. Crane: *John Clifford* (1908); *Life and Letters*, ed. by Sir James Marchant (1924).

CLIFFORD, WILLIAM KINGDON (1845–1879), English mathematician and philosopher, was born on May 4, 1845, at Exeter, where his father was a leading citizen. He was educated at King's college, London, and at Trinity college, Cambridge, where he was elected fellow in 1868. In 1871 he was appointed professor of mathematics at University college, London, and in 1874 became fellow of the Royal Society. In 1875 he married Lucy, daughter of John Lane, of Barbados, well known under her married name as a novelist and dramatist. In 1876 Clifford, a man of high-strung and athletic, but not robust, physique, began to fall into ill-health, and after two voyages to the South, during the third, of pulmonary consumption at Madeira, on March 3, 1879, leaving his widow with two daughters. Mrs. W. K. Clifford (d. 1929) earned for herself a prominent place in English literary life as a novelist, and later as a dramatist. Her best-known story, *Mrs. Keith's Crime* (1885), was followed by several other volumes, the best of which is *Aunt Anne* (1893); and the literary talent in the family was inherited by her daughter Ethel (Lady Fisher Wentworth Dilke), a writer of some charming verse.

Clifford impressed all his contemporaries as a man of extraordinary acuteness and originality; he had also quickness of thought and speech, a lucid style, wit and poetic fancy, and social warmth. He was a mathematician of the front rank, and contrary to the excessively analytic tendency of the Cambridge mathematicians, "above all and before all a geometer." In his theory of graphs he made fruitful suggestions. He was interested in universal algebra, non-Euclidean geometry and elliptic functions, his papers "Preliminary Sketch of Bi-quaternions" (1873) and "On the Canonical Form and Dissection of a Riemann's Surface" (1877) ranking as classics. He also wrote "Classification of Loci" (1878), on algebraic forms and projective geometry.

As a philosopher Clifford's name is chiefly associated with two phrases of his coining, "mind-stuff" and the "tribal self." The latter gives the key to Clifford's ethical view, which explains conscience and the moral law by the development in each individual of a "self" which prescribes the conduct conducive to the welfare of the "tribe." Clifford was prominent in the battle between Darwinian science and Victorian theology.

His works, published wholly or in part after his death, are, *Elements of Dynamic* (1879–87); *Seeing and Thinking*, popular science lectures (1879); *Lectures and Essays* (introduction by Sir F. Pollock, 1879); *Mathematical Papers* (ed. R. Tucker, intro. by J. S. Smith, 1882); and *The Common Sense of the Exact Sciences*, completed by Professor Karl Pearson (1885).

CLIFFSIDE PARK, a borough of Bergen county, New Jersey, U.S.A., on the Palisades overlooking the Hudson river, about opposite rooth street in New York city. The railroad station is Weehawken (*q.v.*). It is a rapidly growing residential suburb, with a population of 5,709 in 1920; and was 15,267 in 1930 by the Federal census.

CLIFTON, watering-place and western residential suburb of Bristol, England, with stations on the G.W.R. and L.M.S.R. It occupies the lofty cliffs overhanging the river Avon (*q.v.*), at a height of 245 ft. above which Brunel's (*q.v.*) famous suspension bridge (1832–64), with a span of 702 ft., bestrides the gorge. The famous hot springs of Clifton (in Hotwells) to which the town owed its rise, issue from the foot of St. Vincent's Rock (308 ft.). The water which has a temperature of about 76° supplies a Spa and pump-room. Immediately above the suspension bridge the Clifton Rocks railway ascends from the quays by the river-side to the heights above. The Clifton and Durdham Downs (both on the Gloucestershire side of the river), form the principal pleasure-grounds of Bristol, commanding a beautiful prospect over the irregularly built city, and over the surrounding well-wooded country.

Three ancient earthworks on Clifton Down bear witness to an early settlement on the spot, and a church was in existence as far back as the time of Henry II., when it was bestowed by William de Clyfton on the abbot of the Austin canons in Bristol; but there is no surviving church older than the 18th century. Clifton gives name to a Roman Catholic bishopric. Clifton college, a public school, was founded in 1862.

CLIFTON, a town of Arizona, U.S.A., on the San Francisco river and the Southern Pacific railway, near the eastern boundary of the State; the county seat of Greenlee county. The population in 1930 was 2,305. It is in the Morenci-Metcalf copper-mining district, which through 1925 had produced 1,657,518,000 lb. of copper. The smelter at Clifton in 1925 treated 179,717 tons of concentrates, yielding 59,272,857 lb. of copper. Clifton was settled about 1870, and was incorporated in 1908. It is the oldest copper-mining camp in the State.

CLIFTON, a city of Passaic county, New Jersey, U.S.A., adjoining the city of Passaic on the north. It is served by the Lackawanna and the Erie railways. The population in 1920 was 26,470 and in 1930 it was 46,875. It has important manufactures, including steel, silk, woollen goods, leather belting, handkerchiefs, chemicals, metal ware and gas-heaters. The factory product in 1925 was valued at \$51,358,862.

CLIFTON FORGE, a city of western Virginia, U.S.A., amid the superb scenery of the Allegheny mountains, on the Jackson river; in Allegheny county, but administratively independent of it. It is on Federal highway 60, and is served by the Chesapeake and Ohio railway. The population in 1920 was 6,164, of whom 1,000 were negroes; in 1930, including the suburbs of Selma, Iron Gate, and Low Moor, it was 6,839 by the Federal census. The city has railroad repair shops, is a distributing point for coal from the near-by fields, and is headquarters of the western division of the Virginia Public Service company. Clifton Forge, formerly called Williamson, was incorporated in 1884. The gap formed here by the river has been used for travel across the mountains ever since the days of the Indians.

CLIMACTERIC, a critical period in human life (from the Gr. *κλιμακτήρ*, the rung or step of a ladder); in a medical sense, the period known as the "change of life," marked in women by the menopause. The word is also used of any turning-point in the history of a nation, a career, etc.

CLIMATE, ARTIFICIAL. The usual significance of the word climate is to indicate the result of all the solar and terrestrial influences or factors which affect animal or vegetable life. These factors include temperature and humidity; gaseous composition; pressure and movement of air; light intensity and quality. An artificial climate may be similarly defined as a more or less mechanical control of one or more of these factors in a comparatively restricted space independent of and in contrast to the natural climate at that particular location. In a broader sense the application of air conditioning to industrial processes might be included under the term artificial climate. In some processes such as the textile industries large quantities of energy, used in driving, spinning and weaving machinery, are liberated as heat in a relatively small space. Air conditioning is important in this case both to provide a liveable humidity and temperature for the employee, and a suitable temperature and humidity for working the fibre. (See AIR CONDITIONING.)

In a more restricted sense artificial climate, as it affects animal or vegetable life, has a more limited application. The mechanical control of temperature and humidity has been used in theatres, schools, churches and other similar public meeting places to insure the comfort and well-being of the audience at all seasons of the year. For this work it has been found that a temperature of about 75° F and a relative humidity of 55% is most comfortable for the average person in summer, while 70° F and 35 to 40% relative humidity are the most satisfactory in winter. In the crowded theatre the problem both summer and winter is to get rid of the heat generated. The average individual radiates sufficient energy as heat to raise the temperature of 30 cu.ft. of air approximately 9° F per minute. From this it is calculated that about 30 cu.ft. of air per person per minute is necessary. The incoming air is normally supplied at a temperature a few degrees lower than the optimum for comfort so that it can function in removing heat from the audience. The air intakes or positive pressure supply openings are usually placed in the ceiling of the room, while the exhaust duct or negative pressure openings are distributed more or less uniformly along the floor, beneath the seats. There is also need for humidification of air in dwelling houses in winter, as it has been

shown that air taken from the outside at a temperature of 32° F or less and heated to 70° is, in general, much too low in humidity for human comfort. Mechanical devices for spraying or otherwise introducing additional water vapor in appreciable amounts are now used for this purpose.

Light has been used in the treatment of human diseases, since Finsen studied the effects of various regions of sunlight and artificial light sources during the years 1893 to 1904. More recently (1918-22) Huldshinsky, Hess and others have shown that the extreme ultra-violet region of sunlight (wave-length 312 to 290 millimicrons) is effective in the cure of the disease rickets, quite generally in animals, and particularly in human beings. Since this time the control of light intensity and quality along with air conditioning has been used in sanatoria and solaria for the treatment of specific diseases and as a general tonic, both physical and mental in its effects on the individual. Human patients have been treated at the Battle Creek sanitarium, Battle Creek, Mich., for several years with a typical installation of this sort. Four carbon arc lamps of about 22 amperes' current consumption placed at a distance of 30 in. from each patient are used in general irradiations at this institution. The air temperature is regulated to about 78° F and relative humidity is maintained at about 70%. The quality of light output of the carbon arc lamps can be altered within limits by using carbons impregnated or cored with different metallic salts. Carbons cored with cerium fluoride are commonly used in the production of a light source which approximates sunlight very closely, both in the visible and ultra-violet regions. More of the extreme ultra-violet beyond wave-length 290 millimicrons can be added by the addition of iron to the core material. Mercury vapour arcs in quartz tubes have also been generally used for irradiating human patients. This light source includes the extreme ultra-violet region which is not found in sunlight and has in addition several bright lines in the visible region and the near ultra-violet. It does not, however, approach sunlight in colour distribution.

The volume concentration of oxygen gas in air has been accurately regulated in hospital rooms designed for the treatment of pneumonia patients at the Rockefeller Institute for medical research, New York city. Oxygen is maintained at about 40% or about twice the normal concentration of the atmosphere in these rooms. The use of such an atmosphere is often successful in supplying sufficient oxygen to the lungs of a patient whose effective lung capacity has been greatly diminished by the disease. Artificial climate has been used at the Boyce Thompson institute for plant research, Yonkers, N.Y., and other similar institutions to study the effects of environmental factors on plant development, reproduction and other life processes. In such a study applied to plants the main factors considered are temperature, humidity and movement of air, carbon dioxide supply, light intensity and quality and day length. Most seed plants grow well within a temperature range of 60 to 80° F but the optimum temperature for growth varies with the species. It may also vary with carbon dioxide supply and light intensity since it has been observed that many plants will grow more rapidly at a higher temperature when carbon dioxide supply and light intensity are both increased. A relative humidity of 50 to 80% is favourable for many seed plants, but desert species exist in nature at a much lower humidity, and some aquatic plants live in a humidity which closely approximates complete saturation. Many common crop plants will increase in growth rate and amount of carbon fixed when solar light intensity is high, if the concentration of carbon dioxide in the atmosphere is increased. The normal concentration is approximately three volumes of this gas in 10,000 of air, while the rate of photosynthesis, or carbon fixation by green plants, increases at least up to 10 times this concentration. This fact was first applied commercially in Germany about 1917 when flue gases from the combustion of coal or coke were purified and the resulting carbon dioxide piped into greenhouses among growing plants. This method has also been used in outdoor plots to increase the concentration of the gas locally over sugar beet fields and other growing crops. More recently pure charcoal briquettes have been burned in open stoves placed inside greenhouses, as a source for carbon dioxide. Increases of 50% or more in the green weight of

plant tissue produced in a given time have been obtained in this way. The success of the method depends in part on light intensity since the plant uses the energy of light to synthesize carbohydrates from the carbon dioxide in the air and water, entering the plant from the soil. In the temperate zones during the winter months, light intensity is too low and day length too short for maximum photosynthesis of a number of plants. This can be overcome by the use of artificial light of a suitable intensity and quality for a few hours each night. Most seed plants grow well in greenhouses in the winter when daylight is supplemented with about six hours of artificial light each night. Longer light periods produce leaf injury or even death in a number of species. Many seed plants can be grown entirely with artificial light as a source of energy for photosynthesis. A room has been equipped for this work at the Boyce Thompson institute for plant research. This room is about 11 ft. square and is illuminated by 25 1,500-watt incandescent type gas-filled lamps arranged in the ceiling so as to give equal distribution of light over the floor area. A false ceiling of glass over which water can be circulated is placed between the lamps and the chamber in which the plants are grown. This serves as a ray filter which absorbs the infra red or heat rays from the lamps. Both temperature and humidity are controlled in this room by standard air conditioning machinery. The refrigeration unit used to cool water for this work has a capacity of 15 tons of ice per 24 hours. The air conditioning system has sufficient capacity to maintain any temperature between 45° and 90° F, accurately regulated in the chamber under the bank of lamps. Carbon dioxide is delivered continuously into the growth chamber through a system of meters so as to maintain a concentration of about 30 parts in 10,000 of air. The effects of temperature, humidity, light intensity, quality and day length, and carbon dioxide supply can be studied in such an artificial climate during the entire life history of the plant.

Many plants grow very rapidly in an artificial climate. Some of the grains such as spring wheat and oats were grown from seed to head in 35 days. Red clover, a biennial in the present system of agriculture, grew from seed to flower in 38 days. Illumination values of the order of 300-1,000-foot candles are required for normal photosynthesis in plants. The light quality must be similar to sunlight, that is, it must contain both the red and blue regions of the spectrum. The gas-filled incandescent type of lamp is not an ideal source of light for plant growth, as it has too much red and infra red and insufficient blue. It has a distinct advantage, however, in that it is easily maintained over long periods of time. It should be noted that day length is an important consideration in the flowering of plants growing in artificial climates. As shown originally by Garner and Allard in 1920, some plants, such as the salvia and cosmos, flower on the short day lengths of fall, spring and winter. Other plants like the lettuce and radish, flower on the long days of summer. A third group, like the buckwheat, is not affected by day length and is, therefore, an everblooming type. These considerations apply equally well when plants are grown under artificial illumination. Day lengths of 15 hours or less usually cause flowering in short day plants, while day lengths greater than this cause flowering only in long day plants or in the everblooming types.

To date there has been no practical application of the growth of plants solely with artificial light in a mechanically controlled environment. Artificial light has been used commercially to supplement sunlight for a short time in forcing especially valuable flowers. With the advent of a more suitable light source and cheaper power, an application may be found in the future.

CLIMATE AND CLIMATOLOGY. The word *clima* (from Gr. κλίμα, to lean or incline) was used by the Greeks for the supposed slope of the earth towards the pole, or for the inclination of the earth's axis. A change of *clima* then meant a change of latitude. The latter was gradually seen to mean a change in atmospheric conditions as well as in length of day, and *clima* thus came to have its present meaning. "Climate" is the average con-

dition of the atmosphere. "Weather" denotes a single occurrence, or event, in the series of conditions which make up climate. The climate of a place is thus in a sense its average weather. Climatology is the study or science of climates; it is a branch of the science of meteorology (*q.v.*).

Climatic Elements and Their Treatment.—Climatology has to deal with the atmospheric conditions which affect human

FIG. 1.—CLIMATOLOGY: DIAGRAM OF RELATIVE AMOUNTS OF INSOLATION RECEIVED AT DIFFERENT LATITUDES IN DIFFERENT MONTHS. Latitudes are shown on left margin, months on right, and values by the vertical distance above the plane of the two margins.

life, viz., temperature (including radiation); moisture (including humidity, precipitation and cloudiness); wind (including storms) and evaporation. Climate deals first with average conditions, but a satisfactory presentation of a climate must take account, also, of regular and irregular daily, monthly and annual changes, and of local departures, mean and extreme, from the average conditions. The mean minimum and maximum temperatures or rainfalls of a month or a season are important data. Further, a determination of the frequency of occurrence of a given condition, or of certain values of that condition, is important, for periods of a day, month or year, as for example the frequency of winds according to direction or velocity; or of different amounts of cloudiness. The probability of occurrence of any condition, as of rain in a certain month, is also a useful thing to know.

Solar Climate.—Climate, in so far as it is controlled solely by the amount of solar radiation which any place receives by reason of its latitude, is called solar climate. Solar climate alone would prevail if the earth had a homogeneous land surface, and if there were no atmosphere. The relative amounts of insolation received at different latitudes and at different times at the upper limit of the earth's atmosphere, i.e., without the effect of absorption by the atmosphere, are shown in fig. 1 after Davis. The latitudes are given at the left margin and the time of year at the right margin. The values of insolation are shown by the vertical distance above the plane of the two margins. At the Equator, where the day is always 12 hours long, there are two maxima of insolation at the equinoxes, when the sun is vertical at noon, and two minima at the solstices when the sun is farthest off the Equator. The values do not vary much through the year because the sun is never very far from the zenith, and day and night are always equal. As latitude increases, the angle of insolation becomes more oblique and the intensity decreases, but at the same time the length of day rapidly increases during the summer, and towards the pole of the hemisphere which is having its summer, the gain in insolation from the latter cause more than compensates for the loss by the former. The double period of insolation above noted for the equator prevails as far as about lat. 12° N. and S.; at lat. 15° the two maxima have united in one, and the same is true of the minima. At the pole there is one maximum at the summer solstice, and no insolation at all while the sun is below the horizon. On June 21 the Equator has a day 12 hr. long, but the sun does not reach the zenith, and the amount of insolation is therefore less

BY COURTESY OF THE UNITED STATES WEATHER BUREAU

INSTRUMENTS FOR RECORDING CONDITIONS OF THE WEATHER

1. Mercurial barometer, invented by Torricelli in 1643. Each tube holds a column of mercury, which rises and falls according to pressure of surrounding air. 2. Anemometer, for measuring velocity of wind. Three cups attached to horizontal arms revolve at speed varying according to wind velocity. 3. Standard 8-in. rain gauge, for measuring fall of rain and snow. 4. Weather recording register equipped to record changes at one-minute intervals. Instrument registers the velocity and direction of wind, rainfall

In hundredths inches and the amount or intensity of sunshine. 5. Thermal sunshine recorder, electrically connected with recording instrument (fig. 4), determines intensity of sunlight. 6. Windvane or anemoscope, indicates direction of the wind. This 4-ft. vane may be connected with the recording instrument (fig. 4.) 7. Standard barograph or recording aneroid barometer with cover removed

than at the equinox. On the northern tropic, however, the sun is vertical at noon, and the day is more than 12 hr. long. Hence the amount of insolation received at this latitude is greater than that received at the equinox at the Equator. From the tropic to the pole the sun stands lower and lower at noon, and the value of insolation would steadily decrease with latitude if it were not for the increase in the length of day. Going polewards from the northern tropic on June 21, the value of insolation increases for a time, because although the sun is lower, the number of hours during which it shines is greater. A maximum value is reached at about lat. $43\frac{1}{2}^{\circ}$ N. The decreasing altitude of the sun then more than compensates for the increasing length of day, and the value of insolation diminishes, a secondary minimum being reached at about lat. 62° . Then the rapidly increasing length of day towards the pole again brings about an increase in the value of insolation, until a maximum is reached at the pole which is greater than the value received at the Equator at any time.

On June 21 there are therefore two maxima of insolation, one at lat. $43\frac{1}{2}^{\circ}$ and one at the north pole. From lat. $43\frac{1}{2}^{\circ}$ N., insolation decreases to zero on the Antarctic circle, for sunshine falls more and more obliquely, and the day becomes shorter and shorter. Beyond lat. $66\frac{1}{2}^{\circ}$ S. the night lasts 24 hours. On Dec. 21 the conditions in southern latitudes are similar to those in the northern hemisphere on June 21, but the southern latitudes have higher values of insolation because the earth is then nearer the sun. At the equinox the days are equal everywhere, but the noon sun is lower and lower with increasing latitude in both hemispheres until the rays are tangent to the earth's surface at the poles (except for the effect of refraction). Therefore, the values of insolation diminish from a maximum at the Equator to a minimum at both poles.

The earth's atmosphere weakens the sun's rays. The more nearly vertical the sun, the less the thickness of atmosphere traversed by the rays. The values of insolation at the earth's surface vary with the condition of the air as to dust, clouds, water vapour, etc. As a rule, even when the sky is clear, about one-half of the solar radiation is lost during the day by atmospheric absorption. The great weakening of insolation at the pole, where the sun is very low, is especially noticeable. The following table (after Angot) shows the effect of the earth's atmosphere (coefficient of transmission 0.7) upon the value of insolation received at sea-level.

Values of Daily Insolation at the Upper Limit of the Earth's Atmosphere and at Sea-Level

| Lat. | Upper limit of atmosphere | | | Earth's surface | | |
|-----------------|---------------------------|--------------|---------|-----------------|--------------|---------|
| | Equator | 40° | N. pole | Equator | 40° | N. pole |
| Winter solstice | 948 | 360 | 0 | 552 | 124 | 0 |
| Equinoxes | 1000 | 773 | 0 | 612 | 411 | 0 |
| Summer solstice | 888 | 1115 | 1210 | 517 | 660 | 494 |

These values are relative only; during the present century the Astrophysical Observatory of the Smithsonian Institution of Washington, under the direction of C. G. Abbot, has estimated the actual intensity of the sun's radiation at the limit of the earth's atmosphere as 1.95 gramme-calories per sq. cm. per minute. (See RADIATION, THEORY OF.) This value is termed the "solar constant," though it varies within about five per cent. on either side of this mean value. The value of 1,000 on the above scale represents about 940 gramme-calories per sq. cm. of horizontal surface.

Physical Climate.—The distribution of insolation explains many of the large facts of temperature distribution; for example, the decrease of temperature from Equator to poles; the double maximum of temperature on and near the Equator; the increasing seasonal contrasts with increasing latitude, etc. But the regular distribution of solar climate between Equator and poles which would exist on a homogeneous earth, whereby similar conditions prevail along each latitude circle, is very much modified by the unequal distribution of land and water; by difference of

altitude; by air and ocean currents, by varying conditions of cloudiness and so on. The uniform arrangement of solar climatic belts arranged latitudinally is interfered with, and what is known as *physical climate* results. According to the dominant control we have solar, continental and marine, and mountain climates. In the first-named, latitude is the essential; in the second and third, the influence of land or water; in the fourth, the effect of altitude.

Classification of the Zones by Latitude Circles.—The five familiar zones are the so-called torrid, the two temperate and the two frigid zones. The torrid zone is limited north and south by the Tropics of Cancer and Capricorn, the Equator dividing the zone into two equal parts. The temperate zones are limited towards the Equator by the Tropics, and towards the poles by the Arctic and Antarctic circles. The two polar zones are caps covering both polar regions, and bounded on the side towards the Equator by the Arctic and Antarctic circles. These are really zones of solar climate. The tropical zone has the greatest annual amount and the least annual variation of insolation. Its annual range of temperature is very slight. Beyond the Tropics the contrasts between the seasons rapidly become more marked. The polar zones have the greatest variation in insolation between summer and winter. They also have the minimum amount of insolation for the whole year; their summer is so short and cool that the heat is insufficient for most forms of vegetation, especially for trees. The temperate zones are intermediate between the tropical and the polar in the matter of annual amount and of annual variation of insolation. Temperate conditions do not characterize these zones as a whole. They are rather the seasonal belts of the world.

Temperature Zones.—The astronomical classification of the zones serves very well for purposes of simple description, but a glance at any isothermal chart shows that the isotherms do not coincide with the latitude lines. In fact, in the higher latitudes, the former sometimes follow the meridians more closely than they do the parallels of latitude. Hence it has been suggested that the zones be limited by isotherms rather than by parallels of latitude, and that a closer approach be thus made to the actual conditions of climate. Supan¹ has suggested limiting the hot belt, which corresponds to, but is slightly greater than, the old torrid zone, by the two mean annual isotherms of 68° F—an isothermal line which approximately coincides with the polar limits of the

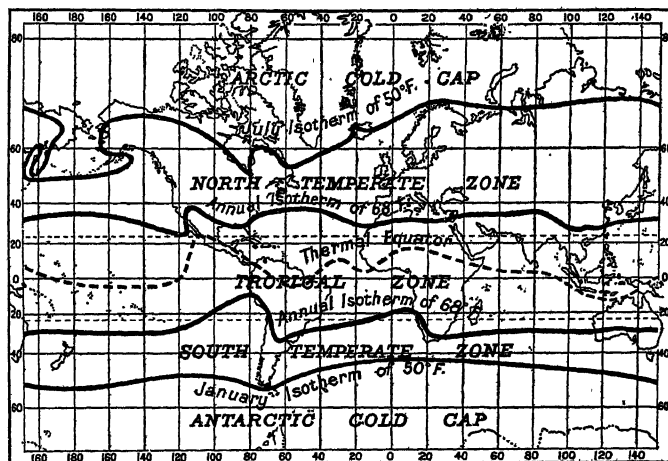

FIG. 2.—DIAGRAM SHOWING ZONES OF TEMPERATURE

trade-winds and with the natural distribution of palms. The limits of these zones, according to the most recent information, are shown in fig. 2. The hot belt widens somewhat over the continents, chiefly because there is a tendency towards an equalization of the temperature between Equator and poles in the oceans, while the stable lands acquire a temperature suitable to their own latitude. Furthermore, the unsymmetrical distribution of land in low latitudes of northern and southern hemispheres makes the hot belt

¹A Supan, *Grundzüge der physischen Erdkunde* (Leipzig, 1896), 88-89. Also *Atlas of Meteorology*, Pl. 1.

extend farther north than south of the Equator. The polar limits of the temperate zones are fixed by the isotherm of 50° F for the warmest month. Summer heat is more important for vegetation than winter cold, and where the warmest month has a temperature below 50° F cereals and forest trees do not grow. The two polar caps are not symmetrical. Extended land masses in high northern latitudes carry the temperature of 50° F in the warmest month farther poleward there than is the case in high southern latitudes occupied by the oceans which warm less easily and are constantly in motion. Hence the southern cold cap, with equatorial limits at about lat. 50° S., is much larger than the northern polar cap. The northern temperate belt in which the great land areas lie is much broader than the southern belt, especially over the continents. These temperature zones emphasize the natural conditions of climate more than is the case in any subdivision by latitude circles, and they bear a fairly close resemblance to the old zonal classification of the Greeks.

Classification of Climates.—The best and most logical form of classification is one which takes account of all the different climatic elements. Such a scheme has been prepared by W. Köppen (*Die Klimate der Erde*, Berlin and Leipzig 1923) and assigns almost as much importance to rainfall as to temperature. Since the rainfall depends largely on prevailing winds, this classification also takes account of the zones of wind. Eight main zones are distinguished and divided and subdivided into a number of climatic provinces and smaller areas. Each subdivision is distinguished by a formula comprised of the main division followed by the initial letters of its characteristics: e.g., the climate of Swakopmund is described as *BWkn*, which means a sub-tropical (B) desert (Wüste) climate with a cold (kalt) winter and frequent fog (Nebel). The eight zones are: A tropical rain zone with the coldest month usually above 64° F and rainfall above the limit of dryness (which varies according to the temperature and the seasonal distribution of rain); two zones of dry (steppe and desert) climate; two zones of warm temperate rain climate with the mean temperature of the coldest month between 64° and 27° F. (these include the "Mediterranean" and most of the "monsoon" climatic areas); a zone of "boreal" or snow and forest climate (with hot summers and cold winters below 27° F), which requires a large area of land and is consequently missing in the southern hemisphere; and two polar caps of "snow climate" with the mean temperature of the warmest month below 50° F.

Marine or Oceanic Climate.—Areas can also be classified climatically according to their position relative to the great land masses, and irrespective of their latitude. Land warms and cools readily, and to a considerable degree; water slowly and but little. The slow changes in temperature of the ocean waters involve retardation in times of occurrence of maxima and minima, and a marine climate, therefore, has cool spring and warm autumn, seasonal changes slight, a prevailingly higher relative humidity, a larger amount of cloudiness, and a heavier rainfall than is found over continental interiors. In middle latitudes oceans have distinctly rainy winters, while over continental interiors the colder months have minimum precipitation. Ocean air is cleaner and purer than land air and is generally in more active motion.

Continental Climate.—Annual temperature ranges increase, as a whole, with increasing distance from the oceans. The coldest and warmest months are usually January and July, times of maximum and minimum temperatures being less retarded than in marine climates. The greater seasonal contrasts in temperature over the continents than over the oceans are furthered by the smaller humidity and cloudiness over the former. Diurnal and annual changes of nearly all elements of climate, irregular as well as regular, are greater over continents than over oceans. Fig. 3 illustrates the annual march of temperature in marine and continental climates. Jacobabad in India (J), and Funchal on the island of Madeira (M) are representative continental and marine stations for a low latitude. Olekminsk in Siberia (Ol) and Lerwick in the Shetlands (L) are good examples of continental and marine climates of higher latitudes in the northern hemisphere.

Owing to distance from chief source of water vapour—the

oceans—air over the larger land areas is drier and dustier than that over the oceans. Yet even in arid continental interiors in summer absolute vapour content is surprisingly large, and in the hottest months percentages of relative humidity may reach 20% or 30%; e.g., in July, Luktschum with an average temperature of 90° and a relative humidity of 31 per cent. has more moisture in the air than Valencia with a temperature of 59° and a relative

humidity of 83 per cent. Cloudiness, as a rule, decreases inland, and with this lower relative humidity, more abundant sunshine and higher temperature, the evaporating power of a continental climate in summer is much greater than that of the more humid, cloudier and cooler marine climate. Both amount and frequency of rainfall, as a rule, decrease inland, but conditions are very largely controlled by local topography and prevailing winds. Winds average somewhat lower in velocity, and calms are more frequent, over continents than over oceans. Seasonal changes of pressure over the former give rise to systems of inflowing and out-flowing, so-called continental winds, sometimes so well developed as to become true monsoons. Extreme temperature changes over continents are the more easily borne because of the dryness of the air; because the minimum temperature of winter occurs when there is little or no wind, and because during the warmer hours of the summer there is the most air-movement.

FIG. 3.—ANNUAL TREND OF AIR TEMPERATURE, SHOWING INFLUENCE OF CLIMATES IN LOW AND HIGH LATITUDES

Desert Climate.—Desert air is notably free from micro-organisms. The large diurnal temperature ranges of inland regions, which are most marked where there is little or no vegetation, give rise to active convectional currents during the warmer hours of the day. Hence high winds are common by day, while the nights are apt to be calm and relatively cool. Diurnal cumulus clouds, often absent because of excessive dryness, are replaced by clouds of blowing dust. Excessive diurnal ranges of temperature cause rocks to split and break up. Wind-driven sand erodes and polishes the rocks. When the separate fragments become small enough they, in their turn, are transported by the winds and further eroded by friction during their journey. Rivers "wither" away, or end in brackish lakes.

Coast or Littoral Climate.—Between pure marine and pure continental types coasts furnish almost every grade of transition. Prevailing winds are here important controls. When these blow from the ocean, climates are marine in character, but when they are off-shore, a modified continental climate prevails, even up to the immediate sea-coast. The former have smaller range of temperature; the air is damp, and there is much cloud. All these marine features diminish with increasing distance from the ocean, especially when there are mountain ranges near the coast. In the Tropics, windward coasts are usually well supplied with rainfall, and temperatures are modified by sea breezes. Leeward coasts in the trade-wind belts offer special conditions. Here deserts often reach the sea, as on the western coasts of South America, Africa and Australia. Cold ocean currents, with prevailing winds along-shore rather than on-shore, are here hostile to cloud and rainfall, although the lower air is often damp, and fog is common in these regions.

Monsoon Climate.—Exceptions to the general rule of rainier eastern coasts in trade-wind latitudes are found in monsoon regions, as in India, for example, where the western coast gets much rain from the south-west monsoon. As monsoons often sweep over large districts, not only coast but interior, a separate group of monsoon climates is desirable. In India there are really three seasons—the cool winter, the hot transition, and the wet summer monsoon. Little precipitation occurs in winter, and that chiefly in the northern provinces. The winter monsoon is normally off-shore and the summer monsoon on-shore, but exceptional cases are found where the opposite is true, as in north-east Ceylon. In higher latitudes the seasonal changes of the winds, although not truly monsoonal, involve differences in temperature and in other climatic elements. The only well-developed monsoons on the coast of the continents of higher latitudes are those of eastern Asia. These are off-shore during the winter, giving dry, clear and cold weather; while the on-shore movement in summer gives cool, damp and cloudy weather.

Mountain and Plateau Climate.—Temperature decreases upwards at an average rate of 3° per 1,000ft., and for this reason and also because of their obstructive effects, mountains are important climatic factors. Mountains as contrasted with lowlands are characterized by decrease in pressure, temperature and absolute humidity; increased intensity of insolation and radiation; usually greater frequency of, and up to a certain altitude more, precipitation. The highest habitations are about 16,000ft. above sea-level, at which altitude pressure has about half its sea-level value. The intensity of the sun's rays is very great in the cleaner, drier and thinner mountain air. Vertical decrease of temperature is especially rapid during warmer months and hours; mountains are then cooler than lowlands. The inversions of temperature characteristic of the colder months, and of the night, give mountains the advantage of a higher temperature then. At such times cold air flows down the mountain sides and collects in the valleys, being replaced by warmer air aloft. Hence diurnal and annual ranges of temperature on the mountain tops of middle and higher latitudes are lessened and the climate in this respect resembles the marine. High enclosed valleys often show continental conditions of large temperature range and such valleys in Europe open to the north-east form local "Siberias." Plateaus, as compared with mountains at the same altitude, have relatively higher temperatures and larger temperature ranges. Altitude tempers heat in low latitudes. High mountain peaks, even on the Equator, can remain snow-covered all the year round.

No general law governs variations of relative humidity with altitude, but on the mountains of Europe winter is the driest season, and summer the dampest. At well-exposed stations there is a rapid increase in the vapour content soon after noon, especially in summer. The same is true of cloudiness, often greater on mountains than at lower levels, and usually greatest in summer when it is least in the lowlands. The higher Alpine valleys in winter have little cloud. This, combined with their low wind velocity and strong sunshine and the night temperature inversions, makes them winter health resorts. Owing to forced ascent of air over rising ground, rainfall usually increases with height up to a certain point, beyond which, owing to loss of water vapour, this increase stops. The zone of maximum rainfall averages about 6,000ft. to 7,000ft. in altitude in intermediate latitudes, being lower in winter and higher in summer. When there is a prevailing wind from one direction, the lee side of the mountains, and the neighbouring lowlands, are relatively dry, forming a "rain shadow." Mountains resemble marine climates in having higher wind velocities than continental lowlands. Mountain summits have a nocturnal maximum of wind velocity, while plateaus usually have a diurnal maximum.

THE TORRID ZONE

Climate and Weather.—Climatic features here are simple and uniform. Periodic phenomena, depending upon the daily and annual march of the sun, are dominant; non-periodic weather changes are wholly subordinate. In special regions only, and at special seasons, is the regular sequence interrupted by an occa-

sional tropical cyclone. These cyclones are comparatively infrequent and generally bring very heavy rains; the devastation one may produce often affects the economic conditions for many years.

Temperature.—Mean temperature is very high, and very uniform over the whole zone, with little variation during the year. The mean annual isotherm of 68° F. is a rational limit at the polar margins of the zone, and the mean annual isotherm of 80° F. encloses the greater portion of the land areas, as well as much of the inter-tropical oceans. The warmest latitude circle for the year is not the equator, but latitude 10° N. The highest mean annual temperatures, shown by the isotherm of 85° F., are in Central Africa, in India, the north of Australia and Central America, but, with the exception of the first, these areas are small. The temperatures average highest where there is little rain. In June, July and August there are large districts in the south of Asia and north of Africa with temperatures over 90° F.

Over nearly all the zone mean annual range of temperature is less than 10° F., and over much of it, especially on the oceans, less than 5° F. Even near the margins of the zone the ranges are less than 25° F., as at Calcutta, Hongkong, Rio de Janeiro and Khartoum. Mean daily range is usually larger than mean annual; "night is the winter of the Tropics." Over parts of the Pacific and Indian oceans from Arabia to the Caroline islands and from Zanzibar to New Guinea, as well as on the Guiana coast, minimum temperatures do not normally fall below 68° F. Towards the margins of the zone, however, the minima on the continents fall to or even below 32° F. Maxima of over 120° F. occur over the deserts of northern Africa and a reading of 136° F. at Azizia in Tunis is the highest known shade temperature. A district where the mean maxima exceed 113° F. extends from the western Sahara to north-western India, and over Central Australia. Near the Equator the maxima are not so high; and inter-tropical oceans show remarkably small variations in temperature.

The Seasons.—In a true inter-tropical climate the seasons depend not on temperature, but on rainfall and the prevailing winds. Life is regulated in some cases almost wholly by rainfall. Although the rain is characteristically associated with a vertical sun, that season is not necessarily the hottest. Towards the margins of the zone, with increasing annual ranges of temperature, seasons in the extra-tropical sense gradually appear. The association of uniformly high heat and humidity at most low-level places near the Equator is very enervating, and energetic physical or mental activity is difficult or impossible for white men. The absence of a bracing cold winter is a great drawback and the uniformity of conditions makes one sensitive to slight changes of temperature. The drier interior regions are more healthy, and the most energetic natives are the desert dwellers.

Pressure, Winds and Rainfall.—Pressure is lowest near the equator, in the belt of doldrums. Here the pressure gradients are small, and calms, variable winds and heavy rain and thunderstorms prevail. This region is one of the rainiest in the world, averaging about 100in., and the sky is generally cloudy; it includes the dense forests of the Amazon and equatorial Africa. The doldrums extend from the Equator to about 10° N., but do not include any part of the southern hemisphere; on either side are the belts of trade winds, the north-east trade from about 10° to 30° N. and the south-east trade from about 0° to 25° S. The trades are extremely regular and stable and except where they strike windward coasts or high mountains they bring fine bracing weather. Over oceans the skies show small detached clouds (trade cumulus) but over the western and central parts of the continents the trade wind latitudes are desert—the Sahara and Arabia, Kalahari and the desert of Australia. The boundaries between the trade winds and the doldrums move north and south following the sun, giving a "winter" dry season and a "summer" rainy season, which near the equator is divided into two by a minor dry season shortly after the summer solstice. Monsoons occur on many of the tropical lands, the best known being those of southern and eastern Asia. In the northern summer the south-west monsoon, warm and moist, blows over the latitudes from about 10°

N. to and beyond the northern tropic, between Africa and the Philippines, giving rains over India, the East Indian archipelago and the eastern coasts of China. In winter, the north-east monsoon, the normal cold-season outflow from Asia, combined with the north-east trade, and generally cool and dry, covers the same district, coming from as far north as lat. 30° N. Crossing the Equator, these winds reach northern Australia and the western islands of the South Pacific as a north-west rainy monsoon, while this region in the opposite season has the normal south-east trade. Other monsoons are found in the Gulf of Guinea and in equatorial Africa. Wherever they occur they control the seasonal changes.

The regular occurrence and cool, clean air of the sea breeze make many districts habitable for white settlers. On not a few coasts the sea breeze is a true prevailing wind. The location of dwellings is often determined by exposure of a site to the sea breeze.

Local thunderstorms are frequent, have a marked diurnal periodicity, find their best opportunity in the equatorial belt of weak pressure gradients and high temperature, and are commonly associated with the rainy season, being most common at the beginning and end of the regular rains. In many places intense thunderstorms occur daily throughout the rainy season.

Cloudiness.—The average cloudiness of the tropics does not differ greatly from that in temperate regions. The mean, in tenths of sky covered, is shown by the following table:—

| Latitude | 30° – 20° N. | 20° – 10° N. | 10° – 0° | 0° – 10° S. | 10° – 20° S. | 20° – 30° S. |
|------------|-----------------------------------|-----------------------------------|----------------------------|----------------------------------|-----------------------------------|-----------------------------------|
| Land . . . | 3.4 | 4.0 | 5.2 | 5.6 | 4.6 | 3.8 |
| Sea . . . | 4.9 | 5.3 | 5.3 | 5.0 | 4.9 | 5.3 |
| Mean . . . | 4.1 | 4.7 | 5.3 | 5.2 | 4.8 | 4.8 |

Both wholly clear and wholly overcast days are rare in the Tropics; the sky is more usually about half clouded.

CLIMATIC SUBDIVISIONS

The Equatorial Belt.—Within a few degrees of the Equator and when not interfered with by other controls, the annual curve of temperature has two maxima following the two zenithal positions of the sun, and two minima at about the time of the solstices. This equatorial type of annual march of temperature is illustrated in the three curves for Brazzaville, Batavia and Ocean island (fig. 4). The greatest range is shown in the curve for Brazzaville, inland in the Congo valley; the curve for Batavia illustrates insular conditions with less range, and that for Ocean island oceanic conditions with a range of only 0.5° F.

As the belt of rains swings back and forth across the Equator after the sun, there should be two rainy seasons with the sun vertical, and two dry seasons when the sun is farthest from the zenith, and while the trades blow. These conditions prevail on the Equator, and as far north and south of the Equator (about 10° – 12°) as sufficient time elapses between the two zenithal positions of the sun for the two rainy seasons to be distinguished from one another. In this belt there is therefore normally no long dry season. The double rainy season is clearly seen in equatorial Africa and in parts of equatorial South America. The maxima lag somewhat behind the vertical sun, coming in April and November, and the first is the greater one. The minima are also unsymmetrically developed, and the so-called "dry seasons" are seldom wholly rainless. This rainfall type with double maxima and minima has been called the equatorial type, and is illustrated in the curves for Entebbe and Bogota (fig. 5). The annual totals are given. These double rainy and dry seasons are easily

FIG. 4.—ANNUAL TREND OF TEMPERATURE FOR EQUATORIAL REGIONS
Heat for Brazzaville (Congo) is greatest

modified by other conditions, as by the monsoons of the Indo-Australian areas, so that there is no rigid belt of equatorial rains extending around the world. In South America, east of the Andes the distinction between rainy and dry seasons is often much confused. The annual variation of cloudiness is illustrated by the curve for Ocean island (Oc) in fig. 6, but the annual period varies greatly under local controls.

At greater distances from the Equator than about 10° or 12° the sun is still vertical twice a year within the Tropics, but the interval between these two dates

is so short that the two rainy seasons merge into one, in summer, and there is also but one dry season, in winter. This is the so-called tropical type of rainfall, and is found where the trade belts are encroached upon by the equatorial rains during the migration of these rains into each hemisphere. It is illustrated in the curves for São Paulo, Brazil, and for the city of Mexico (fig. 5). The tropical type of rainfall occurs beyond the margins of the region of equatorial rainfall and as we go farther towards the lines of the tropics the rainy season shortens to four months or less, lowlands often become parched during the long dry season (winter), while life resumes activity when the rains return (summer). The Sudan receives rains, and its vegetation grows actively when the doldrum belt is north of the equator (May–August). But when the trades blow (December–March) the ground is parched and dusty. The Venezuelan llanos have a dry season in the northern winter, when the trade blows. The rains come in May–October. The campos of Brazil, south of the Equator, have their rains in October–April, and are dry the remainder of the year. The Nile overflow results from the rainfall on the mountains of Abyssinia during the northward migration of the belt of equatorial rains.

FIG. 5.—ANNUAL TREND OF RAINFALL IN TROPICS, TOTALS GIVEN IN INCHES

The so-called tropical type of temperature variation, with one maximum and one minimum, is illustrated in the accompanying curves for Wadi Halfa, in upper Egypt; Alice Springs, Australia; Nagpur, India; and St. Helena (fig. 7). The effect of the rainy season is often shown in a displacement of the time of maximum temperature to an earlier month than the usual one as at Nagpur.

Trade-Wind Belts.—The trade belts near sea-level have fair weather, steady winds, infrequent light rains or even an almost complete absence of rain, very regular, although slight, annual and diurnal ranges of temperature, and constancy and regularity of weather. The climate of ocean areas in the trade-wind belts is indeed the simplest and most equable in the world, the greatest extremes over these oceans being found to leeward of the larger lands. On the lowlands swept over by the trades, beyond the polar limits of the equatorial rain belt (roughly between lats. 20° and 30°), are most of the great deserts of the world. These deserts extend directly to the water's edge on the leeward western coasts of Australia, Africa and America. Ranges and extremes of temperature are much greater over continental interiors than

FIG. 6.—ANNUAL TREND OF CLOUDINESS IN TROPICS, WITH EFFECT OF MONSOON

over oceans in trade-wind belts. Minima of 32° or less occur during clear, quiet nights, and daily ranges of over 50° are common. Midsummer mean temperature rises above 90° , with noon maxima of 110° or more in the non-cloudy, dry air of a desert day. The days, with high, dry winds, carrying dust and sand, with extreme heat, accentuated by absence of vegetation, are disagreeable, but the calmer nights, with active radiation under clear skies, are much more comfortable. Nocturnal temperatures are often low, and thin sheets of ice may form.

While the trades are drying winds as long as they blow strongly over the oceans, or over lowlands, they readily become rainy if cooled by ascent. Hence the windward eastern sides of mountains or bold coasts in the trade-wind belts are well watered, while the leeward sides, or interiors, are dry. Mountainous islands in the trades, like the Hawaiian islands, many of the East and West Indies, the Philippines, Borneo, Ceylon, Madagascar, Tenerife, etc., show marked differences of this sort. The eastern coasts of Guiana, Central America, south-east Brazil, south-east Africa and eastern Australia are well watered, while the interiors are dry. South America in the south-east trade belt is not well enclosed on the east and the most arid portion is an interior district close to the eastern base of the Andes where the land is low. Even far inland the Andes again provoke precipitation along their eastern slopes and the narrow Pacific coastal strip to leeward of the Andes is a very pronounced desert from near the equator to about lat. 30° S. The cold ocean waters, with prevailing southerly (drying) winds alongshore, are additional factors causing this aridity. The rainfall associated with the conditions just described is known as the *trade* type, and has a maximum in winter when the trades are most active. In cases where the trade blows steadily throughout the year against mountains or bold coasts, as on the Atlantic coast of Central America, there is no real dry season. The curve for Hilo (mean annual rainfall 145.24 in.) on the windward side of the Hawaiian islands, shows typical conditions (see fig. 5).

Monsoon Belts.—In a typical monsoon region the rains follow the vertical sun, and therefore have a simple annual period much like that of the tropical type above described. This monsoon type of rainfall is well illustrated in the curve for Port Darwin in Australia (see fig. 5). This summer monsoon rainfall results from the inflow of a body of warm, moist air from the sea upon a land area, the rainfall being particularly heavy where the winds have to climb over high lands. In India, the precipitation is heaviest in Assam (where Cherapunji, at the height of 4,455 ft. in the Khasi hills, has a mean annual rainfall of between 400 in. and 500 in.), on the bold western coast of the peninsula (western Ghats) (120 in. and over), and on the mountains of Burma (up to 226 in.). In the rain-shadow of the western Ghats, the Deccan often suffers from drought and famine unless the monsoon rains are abundant and well distributed. The prevailing direction of the rainy monsoon wind in India is south-west; on the Pacific coast of Asia, it is south-east. This monsoon district is very large, including the Indian ocean, Arabian sea, Bay of Bengal, and adjoining continental areas; the Pacific coast of China, the Yellow and Japan seas and numerous islands from Borneo to Sakhalin on the north and to the Ladrone islands on the east. A typical temperature curve for a monsoon district is that for Nagpur, in the Deccan (fig. 7), and a typical monsoon cloudiness curve is given in fig. 6, the maximum coming near the time of

the vertical sun, in the rainy season, and the minimum in the dry season.

In the Australian monsoon region, which reaches across New Guinea and the Sunda islands, and west of Australia, in the Indian ocean, over latitudes 0° – 10° S., the monsoon rains come with north-west winds between November and March or April. The general rule that eastern coasts between the Tropics are the rainiest finds exceptions in the case of the rainy western coasts in India and other districts with similar monsoon rains. On the coast of the Gulf of Guinea, for example, there is a small rainy monsoon area during the summer; heavy rains fall on the seaward slopes of the Cameroon Mountains where Debundscha averages 369 inches. Gorée, lat. 15° N., on the coast of Senegambia, gives a fine example of a rainy (summer) and a dry (winter) monsoon. In island groups such as the Malay Archipelago where trade winds alternate with monsoons the annual variation of rainfall becomes very complex.

Mountain Climate.—In the torrid zone altitude is chiefly important because of its effect in tempering the heat of the lowlands, especially at night. If mountains are high enough, they carry snow all the year round, even on the Equator. The highlands and mountains within the Tropics are thus often sharply contrasted with the lowlands, and offer more agreeable conditions in Africa and South America. In India, the hill stations are crowded during the hot months by Europeans. The climate of many tropical plateaus and mountains has the reputation of being a "perpetual spring." The rainfall between the Tropics on mountains and highlands often differs considerably in amount from that on the lowlands, and other features common to mountain climates the world over are also noted.

TEMPERATE ZONES

The designation "temperate" is appropriate for the middle latitudes of the southern hemisphere and of the oceans and western coasts in the northern hemisphere, but not for the continental interiors and eastern coasts of Asia and North America, for which Köppen's term "boreal" is better. The temperate zones as a whole are however characterized by the extreme changeableness of their weather, resulting from the frequent passage of barometric depressions.

Temperature.—The annual range of temperature exceeds the diurnal range in all parts of the temperate zone, but the former varies greatly from one part to another. It is smallest on windward islands and coasts and greatest in the interior of the continents, but nearer the east coasts than the west. Thus at Lerwick the range is 15° F from 38° F in February to 53° F in August, while at Yakutsk in Siberia it is 112° F from -46° F in January to 66° F in July, and the average difference between two consecutive months at Yakutsk is greater than the change in six months at Lerwick. Even at Vladivostok on the Pacific coast of Siberia the mean annual range is 61° . The southern part of the temperate zone in central Asia has very hot summers; thus Lukitchun in 43° N. has a mean July temperature of 90° and a mean daily maximum in that month of 109° . Over much of the oceans of the temperate zones the annual range is less than 10° . In the south temperate zone there are no extreme ranges, the maxima, slightly over 30° , being near the margin of the zone in the interior of South America, Africa and Australia.

The north-east Atlantic and north-western Europe are about 35° too warm for their latitude in January, while north-eastern Siberia is 30° too cold. The lands north of Hudson bay are 25° too cold, and the waters of the Alaskan bay 20° too warm. In July, and in the southern hemisphere, anomalies are small. The diurnal variability of temperature is greater in the north temperate zone than elsewhere and the same month may differ greatly in its character in different years. The annual temperature curve has one maximum and one minimum. In the continental type the times of maximum and minimum are about one month behind the solstices. In the marine type the retardation may amount to nearly two months. Coasts and islands have a tendency to a cool spring and warm autumn; continents, to similar temperatures in both spring and autumn.

FIG. 7.—ANNUAL TREND OF TEMPERATURE: TROPICAL TYPE IN NORTHERN AND SOUTHERN HEMI-SPHERES

Pressure and Winds.—Over the oceans pressure decreases steadily from the sub-tropical anticyclones to the semi-permanent low pressure areas in about lat. 60° . Hence the prevailing winds are westerly but they are frequently disturbed by the passage of barometric depressions, and the wind may blow from any direction. In the northern hemisphere pressure is higher over the continents than over the oceans in winter, but higher over the oceans than the continents in summer. Hence winter is the stormiest season over the oceans and the prevailing winds become south-westerly on the western coasts of the continents and northerly on the eastern coasts, while in summer they are north-westerly on the western and south-easterly on the eastern coasts. These seasonal changes are best developed on the eastern coast of Asia, where they have the regularity of true monsoons. The winter anticyclone of central Asia has produced the highest known readings of pressure. In the southern hemisphere the seasonal changes are less marked, owing to the preponderance of water, and between lat. 40° and 50° S. the winds blow from some westerly point with considerable regularity and force. These are the "roaring forties" or "brave west winds." Between 50° and 60° S. the winds, while still mainly westerly, are more irregular in direction owing to the frequent passage of storm-centres. Winter in these latitudes is stormier than summer, but seasonal difference is less than north of the Equator.

Rainfall.—Rainfall is fairly abundant over the oceans and also over a considerable part of the lands (30–80 in. and more). It comes chiefly in connection with the usual cyclonic storms, or in thunderstorms. The variations, geographic and periodic, in rainfall produced by differences in temperature, topography, cyclonic conditions, etc., are very complex. The equatorial margin of the temperate zone rains is clearly defined on the west coasts, at points where coast deserts are replaced by belts of light or moderate rainfall. Bold west coasts, on the polar side of lat. 40° , are very rainy (100 in. to 200 in. a year in special situations). The hearts of the continents, far from the sea, especially when well enclosed by mountains, or when blown over by cool ocean winds which warm while crossing the land, have light rainfall (less than 20 in.). East coasts are wetter than interiors but drier than west coasts. Autumn and winter are the seasons of maximum rainfall over oceans, islands and west coasts, for the westerlies are then most active, cyclonic storms are most numerous and best developed, and the relatively cold lands chill inflowing damp air. In winter, however, low temperatures, high pressures, and tendency to outflowing winds over continents are unfavourable to rainfall, and the interior land areas as a rule then have their minimum. The warmer months bring the maximum rainfall over the continents. Conditions are then favourable for inflowing damp winds from the adjacent oceans; there is the best opportunity for convection; thunder-showers readily develop on the hot afternoons; the capacity of the air for water vapour is greatest. The marine type of rainfall, with a winter maximum, extends in over the western borders of the continents, and is also found in the winter rainfall of the sub-tropical belts. Rainfalls are heaviest along the tracks of most frequent cyclonic storms. For continental stations the typical daily march of rainfall shows a chief maximum in the afternoon, and a secondary maximum in the night or early morning. The chief minimum comes between 10 A.M. and 2 P.M. Coast stations generally have a night maximum and a minimum between 10 A.M. and 4 P.M.

Humidity and Cloudiness.—Relative humidity is high (80–90%) over the oceans and western coasts and islands. On the eastern coasts and the neighbouring parts of the continents which come under the influence of the inblowing summer winds relative humidity is high in summer but low in winter. In the dry interior of the continents relative humidity is low (20–40%) in summer, though owing to the great heat the absolute humidity may be surprisingly high. In winter in the cold interiors the reverse holds; the absolute humidity is very low but the relative humidity comparatively high. Owing to difficulties of measurement at low temperatures, however, the data available are of doubtful accuracy.

The distribution of cloudiness resembles that of humidity, rang-

ing from one-tenth in the interior deserts to nine-tenths in the oceanic storm areas. The averages for different latitudes are as follows:

| Latitude | 60° – 50° N. | 50° – 40° N. | 40° – 30° N. | 30° – 40° S. | 40° – 50° S. | 50° – 60° S. |
|----------|-------------------------------|-------------------------------|-------------------------------|-------------------------------|-------------------------------|-------------------------------|
| Land . | 6.0 | 5.0 | 4.0 | 4.8 | 5.8 | 7.0 |

Seasons in the temperate zones are classified according to temperature, not, as in the Tropics, by rainfall. The four seasons are important characteristics, especially of the middle latitudes of the north temperate zone. Towards the equatorial margins of the zones the difference in temperature between summer and winter becomes smaller, and the transition seasons weaken and even disappear. At the polar margins the change from winter to summer, and vice versa, is so sudden that there also the transition seasons disappear. These seasonal changes are of the greatest importance in the life of man. The monotonous heat of the Tropics and the continued cold of the polar zones are both depressing. The seasonal changes of the temperate zones stimulate man to activity and encourage higher civilization.

Climatic Subdivisions.—There are fundamental differences between north and south temperate zones. Marginal sub-tropical belts must also be considered as a separate group by themselves. The north temperate zone includes large and diverse areas of land, stretching over many degrees of latitude, as well as of water, and has a remarkable diversity of climates. Thus there are the ocean areas and the land areas. The latter are then subdivided into western (windward) and eastern (leeward) coasts and interiors. Mountain climates remain as a separate group.

South Temperate Zone.—Because of the large ocean surface, the régime in the south temperate zone is more uniform than in the northern. The south temperate zone may properly be called "temperate." Temperature changes are small, prevailing winds are stronger and steadier than in the northern hemisphere; seasons are more uniform; weather is prevailingly stormier, more changeable, and more under cyclonic control. The uniformity of the climatic conditions over the far southern oceans is monotonous. The continental areas are small, and develop to a limited degree only the more marked seasonal and diurnal changes which are characteristic of lands in general. Summers are less stormy than winters, but even summer temperatures are not high. New Zealand, with mild climate and fairly regular rains, is really at the margin of the zone, and has much more favourable conditions than the islands farther south, which have dull, cheerless climates. The zone enjoys a good reputation for healthfulness, which fact has been ascribed chiefly to the strong and active air movement and the cool summers. It must be remembered, also, that the lands are mostly in the sub-tropical belt, which possesses peculiar climatic advantages; as will be seen.

Sub-tropical Belts: Mediterranean Climates.—At the tropical margins of the temperate zones are the so-called sub-tropical belts. Their rainfall régime is alternately that of the westerlies and of the trades. In winter the equatorward migration of the great pressure and wind systems brings these latitudes under the control of the westerlies, whose frequent irregular storms give a moderate winter precipitation. These winter rains are not steady and continuous, but are separated by spells of fine sunny weather. The amounts vary greatly; much of the area has less than 20 in., but Crkvice, on the Gulf of Cattaro, has 183 in. In summer, when the trades are extended polewards by the out-flowing equatorward winds on the eastern side of the ocean anticyclones, mild, dry and nearly continuous fair weather prevails, with northerly winds blowing towards the tropic.

Sub-tropical belts of winter rains and dry summers are mainly limited to western coasts of continents, and to the islands off these coasts in latitudes between about 28° and 40° . The sub-tropical belt is exceptionally wide in the Old World, and reaches far inland there, embracing countries bordering on the Mediterranean in southern Europe and northern Africa, and then extend-

ing eastward across the Dalmatian coast and the southern part of the Balkan peninsula into Syria, Mesopotamia, Arabia, north of the tropic, Persia and adjacent lands. This distribution has led to the use of the name "Mediterranean climate." Owing to great irregularity of topography and outline, the Mediterranean province embraces many varieties of climate, but the dominant characteristics are the mild temperatures, except on the heights, and the winter rains.

On the western coasts of the two Americas the sub-tropical belt of winter rains is clearly seen in California and in north Chile, on the west of the coast mountains. Between the region which has rain throughout the year from the stormy westerlies, and the districts which are permanently arid under the trades, there is an indefinite belt over which rains fall in winter. In south Africa, which is controlled by high pressure areas of the south Atlantic and south Indian oceans, the south-western coastal belt has winter rains, decreasing to the north while the east coast and adjoining interior have summer rains, from the south-east trade. Southern Australia is climatically similar to south Africa. In summer the trades give rainfall on the eastern coast decreasing inland. In winter the westerlies give moderate rains, chiefly on the south-western coast. Sub-tropical climates follow the tropical high pressure belts across the oceans, but do not retain their distinctive character far inland from the west coasts of the continents (except in the Mediterranean), nor on the east coasts. On the latter, summer monsoons and the occurrence of general summer rains interfere, as in east Asia and in Florida.

Strictly, winter rains are typical of the coasts and islands of this belt. The more continental areas have a tendency to spring and autumn rains. The rainy and dry seasons are most marked at the equatorward margins of the belt. With increasing latitude, the rain is more evenly distributed through the year, the summer becoming more and more rainy until, in the continental interiors of the higher latitudes, summer becomes the season of maximum rainfall. The monthly distribution of rainfall in two sub-tropical regions is shown in the accompanying curves for Malta and for Perth (Western Australia) (fig. 8). In Alexandria the dry season lasts nearly eight months; in Palestine from six to seven months; in Greece about four months. The winter rains which migrate equatorward are separated by the Sahara from the equatorial rains which migrate poleward. Large variations in annual rainfall may be expected towards the equatorial margins of sub-tropical belts.

The main features of the sub-tropical rains east of the Atlantic are repeated on the Pacific coasts of the two Americas. In North America the rainfall decreases from Alaska, Washington and northern Oregon southwards to lower California, and the length of the summer dry season increases. At San Diego, six months (May-October) have each less than 5% of the annual precipitation, and four of these have 1%. The southern extremity of Chile, from about latitude 38° S. southward, has heavy rainfall throughout the year from the westerlies, with a winter maximum. Northern Chile is persistently dry. Between these two there are winter rains and dry summers. Neither Africa nor Australia extends far enough south to show the different members of this system well. New Zealand is almost wholly in the prevailing westerly belt. Northern India is unique in having summer monsoon rains and also winter rains, the latter from weak cyclonic storms which correspond with sub-tropical winter rains.

From the position of the sub-tropical belts to leeward of the oceans, and at the equatorial margins of the temperate zones, it follows that their temperatures are not extreme. Further, the protection afforded by mountain ranges, as by the Alps in Europe and the Sierra Nevada in the United States, is an important factor

in keeping out extremes of winter cold. The annual march and ranges of temperature depend upon position with reference to continental or marine influences (fig. 9). The Mediterranean basin is particularly favoured in winter, not only in the protection against cold afforded by the mountains, but also in the high temperature of the sea itself. The southern Alpine valleys and the Riviera are well situated, having good protection and a southern exposure. The coldest month usually has a mean temperature well above 32°. Mean minimum temperatures of about, and somewhat below, freezing occur in the northern portion of the district, and in the more continental localities such as northern Spain and the Balkans minima a good deal lower have been observed. Somewhat similar conditions obtain in the sub-tropical district of North America. Under the control of passing cyclonic storm areas, hot or cold winds, which often owe some of their special characteristics to the topography, bring into the sub-tropical belts, from higher or lower latitudes, unseasonably high or low temperatures. These winds have been given special names (mistral, sirocco, bora, etc.). Cloudiness is moderate in winter but very small in summer. The winter rains do not bring continuously overcast skies, and a summer month with a mean cloudiness of one tenth is not exceptional in the drier parts of the sub-tropics.

FIG. 9.—ANNUAL TREND OF TEMPERATURE FOR SELECTED SUBTROPICAL STATIONS

temperatures and moderate rainfall, the sub-tropical belts possess many climatic advantages which fit them for health resorts. The long list of well-known resorts on the Mediterranean coast, and the shorter list for California, bear witness to this fact.

North Temperate Zone: West Coasts:—Marine climatic types are carried by the prevailing westerlies on to the western coasts of the continents, giving them mild winters and cool summers, abundant rainfall, and a high degree of cloudiness and relative humidity. North-western Europe is particularly favoured because of the remarkably high temperatures of the north Atlantic Ocean. January means of 40° to 50°F in the British Isles and on the northern French coast occur in the same latitudes as those of below 0° in the far interior of Asia. In July means of 60° to 70° in the former contrast with 70° to 80°F in the latter districts. The conditions are somewhat similar in North America. Along the western coasts of North America and of Europe the mean annual ranges are under 25°—actually no greater than some of those between the tropics. Irregular cyclonic temperature changes, are, however, marked in the temperate zone, while absent between the Tropics. The figures for the Scilly isles and for Thorshavn, Farøe islands, illustrate the insular type of temperature on the west coasts. The annual march of rainfall, with the slight maximum in the autumn and winter characteristic of the marine régime, is illustrated in the curve for north-western Europe (fig. 10). On the northern Pacific coast of North America the distribution is similar, and in the southern hemisphere the western coasts of southern America, Tasmania and New Zealand show the same type. The cloudiness and relative humidity average high on western coasts, with the maximum in the colder season.

Continental Interiors.—The equable climate of western coasts changes, gradually or suddenly, into the more extreme climates of the interiors. In Europe, where no high mountain ranges intervene, the transition is gradual, and broad stretches benefit by the tempering influences of the Atlantic. In North America the

change is abrupt and comes on crossing the lofty western mountain barrier. The figures in the accompanying table illustrate well the gradually increasing continentality of climate with increasing distance inland in Eurasia. Continental interiors of the north temperate zone have the greatest extremes in the world. Towards the arctic circle winters are extremely severe, and January mean temperatures of -10° and -20° are widespread. At the cold pole of north-east Siberia a January mean of -60° is found. Mean minimum temperatures of -40° occur in the area from eastern Russia, over Siberia and down to about latitude 50° N. Over no small part of Siberia minimum temperatures below -70° may be looked for every winter. Thorshavn and Yakutsk are excellent examples of temperature differences along the same latitude line. Fortunately in Siberia the lowest temperatures are always accompanied by calm weather. A temperature of 0° accompanied by a strong wind is harder to bear than -50° in a calm, and the gales (*buran*, *purga*), which carry loose snow, are very dangerous. North American winter weather in middle latitudes is often interrupted by cyclones, which, under the steep poleward temperature gradient then prevailing, cause frequent, marked and sudden changes in wind direction and temperature over the central and eastern United States. Cold waves and warm waves are common, and blizzards resemble the *buran* or *purga* of Russia and Siberia. With cold northerly winds, temperatures below freezing are carried far south towards the tropic.

The January mean temperatures in the southern portions of the continental interiors average about 50° . In summer the northern continental interiors are warm, with July means of 60° and thereabouts. These temperatures are not much higher than those on the west coasts, but as the northern interior winters are much colder than those on the coasts, the interior ranges are very large. Mean maximum temperatures of 86° occur beyond the Arctic circle in north-eastern Siberia, and beyond latitude 60° in North America. In spite of the extreme winter cold, agriculture extends remarkably far north in these regions, because of warm, though short summers, with favourable rainfall distribution. Summer heat is sufficient to thaw the upper surface of the frozen ground, and vegetation prospers for its short season; great stretches of flat surface become swamps. The southern interiors have torrid heat in summer, temperatures of over 90° being recorded in the south-western United States and in southern Asia. The diurnal ranges of temperature are very large, often exceeding 40° , and mean maxima exceed 110° .

The winter maximum of rainfall and cloud on the west coasts becomes a summer maximum in the interiors. The change is gradual in Europe, as is the change in temperature, but more sudden in North America. The rainfall curves for central Europe and for northern Asia illustrate these continental summer rains (see fig. 10). The summer maximum becomes more marked with increasing continental character of the climate. There is also a well-marked decrease in the amount of rainfall inland. In western Europe rainfall averages 20 in. to 30 in., with much larger amounts (reaching 120 in. and even more) on bold west coasts, as in the British Isles and Scandinavia, where moist Atlantic winds are deflected upwards, and also locally on mountain ranges, as on the Alps. There are small rainfalls (below 20 in.) in eastern Scandinavia and on the Iberian peninsula. Eastern Europe has generally less than 20 in., western Siberia about 15 in., and eastern Siberia about 10 in. In the southern part of the great overgrown continent of Asia an extended region of steppes and deserts, too far from the sea to receive sufficient precipitation, shut in, furthermore, by

mountains, controlled in summer by drying northerly winds, receives less than 10 in. a year, and in places less than 5 in.

The North American interior because of its small area has more favourable rainfall conditions than Asia. The heavy rainfalls on the western slopes of the Pacific coast mountains correspond, in a general way, with those on the western coast of Europe. The coast mountains cause a much more rapid decrease of rainfall inland than in Europe and a considerable south-western interior region has deficient rainfall (less than 10 in.). The eastern part of the continent is freely open to the Atlantic and the Gulf of Mexico, so moist cyclonic winds have access, and rainfalls of over 20 in. are found everywhere east of the 100th meridian. These conditions are much more favourable than those in eastern Asia. The greater part of the interior of North America has the usual warm-season rains. In the interior basin, between the Rocky and Sierra Nevada mountains, the higher plateaux and mountains receive much more rain (largely from thunderstorms) than the desert lowlands. Forests grow on the higher elevations, while irrigation is necessary for agriculture below. In southern South America the narrow Pacific slope has heavy rainfall (over 80 in.); east of the Andes the plains are dry (mostly less than 10 in.). The southern part of the continent is very narrow, and is open to the east as well as more open to the west owing to decreasing height of the mountains. Hence the rainfall increases somewhat to the south with passing cyclones. Tasmania and New Zealand have most rain on their western slopes.

East Coasts.—Prevailing winds carry the interior continental climates off over the eastern coasts of the temperate zone lands and even on to the adjacent oceans. The east coasts therefore have continental climates, with modifications resulting from the presence of the oceans to leeward, and have little in common with the west coasts. On west coasts of north temperate lands isotherms are far apart. On east coasts they crowd together. The east coasts share with the interiors large annual and cyclonic ranges of temperature. A glance at isothermal maps of the world will show at once how favoured, because of its position to leeward of the warm

FIG. 10.—ANNUAL TREND OF RAINFALL IN NORTH TEMPERATE ZONE, IN THOUSANDTHS OF ANNUAL TOTALS

North Atlantic waters, is western Europe as compared with eastern North America. A similar contrast, less marked, is seen in eastern Asia and western North America. In eastern Asia coast mountains give some shelter from extreme cold of the interior, but in North America, with no such barrier, severe cold winds sweep across the Atlantic coast States, even far to the south. Owing to prevailing offshore winds, oceans to leeward have relatively little effect.

The rainfall increases from the interiors towards the east coasts. In North America the distribution through the year is very uniform, with some tendency to a summer maximum, as in the interior (N. A. fig. 10). In eastern Asia winters are relatively dry and clear, under the influence of the cold offshore monsoon, and summers are warm and rainy. Rainfalls of 40 in. are found on the east coasts of Korea, Kamchatka and Japan, while in North America, which is more open, they reach farther inland. Japan, although occupying an insular position, has a modified continental

rather than a marine climate. The winter monsoon after crossing the water, gives abundant rain and snow on the western coast, while the winter is relatively dry in the lee of the mountains, on the east. Japan has smaller temperature ranges than the mainland.

Mountain Climates.—If the altitude is sufficient, decreased temperature gives mountains a polar climate, with the difference that summers are relatively cool while winters are mild owing to inversions of temperature in anticyclonic weather. Hence annual ranges are smaller than over lowlands. At such times of inversion mountain-tops often appear as local areas of higher temperature in a general region of colder air over valleys and lowlands. Increased intensity of insolation aloft is important for certain mountain resorts in winter (e.g., Davos and Meran). Of Meran it has been well said that from December to March the nights are winter, but the days are mild spring. The diurnal ascending air currents of summer usually give mountains their maximum cloudiness and highest relative humidity in the warmer months, while winter is the drier and clearer season.

CHARACTERISTICS OF THE POLAR ZONES

The temperate zones merge into the polar zones at the Arctic and Antarctic circles, or, if temperature be used as the basis of classification, at the isotherms of 50°F for the warmest month, as suggested by Supan. The longer or shorter absence of the sun gives the climate a peculiar character. Beyond the isotherm of 50°F for the warmest month forest trees and cereals do not grow. In the northern hemisphere this line is well north of the Arctic circle, in the continental climate of Asia, and north of it also in north-western North America and in northern Scandinavia, but falls well south in eastern British America, Labrador and Greenland, and also in the north Pacific Ocean. In the southern hemisphere this isotherm crosses the southern extremity of South America, and runs fairly east and west around the globe. There is a minimum of life, but more in the north polar than the south polar zone. Plants and land animals are few. Farming and cattle raising cease. Population is small and scattered. Man seeks his food chiefly in the sea and lives near the sea-coast. There are no permanent settlements at all within the Antarctic circle. Interior lands are deserted. Arctic vegetation must make rapid growth in the short, cool summer. In the highest latitudes summer temperatures are not high enough to melt snow on a level. Arctic plants grow and blossom rapidly and luxuriantly where the exposure is favourable, and the water from melting snow can run off; the soil then dries quickly and can be effectively warmed. Protection against cold winds is another important factor. Over great stretches of the northern plains the surface only is thawed out in the warmer months, and swamps, mosses and lichens are found over perpetually frozen ground.

Temperature.—At the solstices the two poles receive the largest amounts of insolation which any part of the earth's surface ever receives. Temperatures do not follow insolation in this case because much of the latter never reaches the earth's surface and because much energy which does reach the surface is expended in melting snow and ice of the polar areas. In the winter months there are three cold poles, in Siberia, in Greenland and at the pole itself. In January the mean temperatures at these three cold poles are -49°, -40° and -40° F respectively. The Siberian cold pole becomes a maximum of temperature during the summer, but the Greenland and polar minima remain throughout the year. In July the temperature distribution shows considerable uniformity; the gradients are relatively weak. A large area in the interior of Greenland, and one of about equal extent around the pole, are within the isotherm of 32°. For the year a large area around the pole is enclosed by the isotherm of -4°, with an isotherm of the same value in the interior of Greenland. The annual range of temperature is about 120° in Siberia, 80° in North America, 76° at the North Pole and 72° in Greenland. The North Pole obviously has a continental climate.

For the Antarctic our knowledge is still very fragmentary, and relates chiefly to summer months. Meinardus has determined mean temperatures of higher southern latitudes as follows:—

| Mean Temperatures of High Southern Latitudes | | | | | |
|--|-------|-------|-------|--------|--|
| S. Lat. | 50° | 60° | 70° | 80° | |
| Mean Annual | 41.9F | 24.6F | 8.1F | -12.5F | |
| January | 46.9 | 34.2 | 29.7 | 18.7 | |
| July | 37.4 | 13.5 | -11.0 | -33.3 | |

The whole southern hemisphere is colder than the northern. Antarctic summers are decidedly cold. Mean annual temperatures are about 10°, and minima of an ordinary Antarctic winter go to -40° and below, but so far no minima of the severest Siberian intensity have been noted. Maxima have varied between 35° and 50°. Temperatures at the South Pole itself suggest interesting speculations. It is likely that near the South Pole will prove to be the coldest point on the earth's surface for the year, as the distribution of insolation implies and as the conditions of land, ice and snow there suggest. The lowest winter and summer temperatures in the southern hemisphere will probably be found near the pole. Isotherms in the antarctic region bend polewards and equatorwards at different meridians, although much less so than in the Arctic.

The annual march of temperature in the north polar zone, for which we have the best comparable data, is peculiar in having a much retarded minimum in February or even in March—the result of the long cold winter. Temperature rises rapidly towards summer, reaching a maximum in July. Autumn is warmer than spring. The continents do not penetrate far enough into the Arctic zone to develop a pure continental climate in the highest latitudes. Verkhoyansk, latitude 67° 6'N., has an exaggerated continental type for the margin of the zone, with an annual range of 120°. One-third as large a range is found on Novaya Zemlya. Polar climate as a whole has large annual and small diurnal ranges, but sudden changes of wind may cause marked irregular temperature changes especially in winter. The smaller ranges are associated with greater cloudiness, and vice versa.

Pressure and Winds.—Pressure and winds follow a simpler scheme in the southern than in the northern hemisphere, because of the large extent of ocean. The southward decrease of pressure in temperate latitudes, previously described, ceases in about 60°S., where a trough of low pressure encircles the globe, widening somewhat over the Ross and Weddell Seas, while still farther south pressure rises again. On the northern side of this trough westerly winds prevail, on the southern side easterly winds. Over the Antarctic continent itself periods of calm, and, in winter, intense cold alternate with periods of high winds, which often develop into blizzards. Blizzards are not equally developed on all parts of the Antarctic coast, their frequency depending on the local topography and distribution of pressure; they are especially numerous in Adelie Land. Winds of any force sweep away the surface layer of cold air and cause a marked rise of temperature. They whirl up the loose surface snow but are also accompanied by fresh snow, and visibility is limited to a few yards.

In the Arctic area wind systems are less clearly defined and pressure distribution is much less regular, on account of irregular distribution of land and water. The North Atlantic low-pressure area is more or less well developed in all months. Except in June, when it lies over Southern Greenland, this tongue-shaped trough of low pressure lies in Davis strait, to the south-west or west of Iceland, and over the Norwegian sea. In winter it greatly extends its limits farther east into the inner Arctic ocean, to the north of Russia and Siberia. The Pacific minimum of pressure is found south of Bering strait and in Alaska. Between these two regions a ridge of higher pressure extends from North America to eastern Siberia. This has been called by Supan the "*Arktische Windscheide*." Pressure gradients are steepest in winter. The prevailing westerlies which in the high southern latitudes are so symmetrically developed, are interfered with by the varying pressures over the northern continents and oceans in summer and winter. Iso-baric and wind charts show that on the whole winds blow out from the inner polar basin, especially in winter and spring.

Rain and Snow.—The amount of precipitation is comparatively slight in the polar zones, chiefly because of the small capacity of the air for water vapour at the low temperatures there prevailing; partly also because of the rarity of local convectional

storms and thunder-showers. Even cyclonic storms cannot yield much precipitation. Extended snow and ice fields tend to give an exaggerated idea of the actual amount of precipitation. It must be remembered, however, that evaporation is slow at low temperatures, and melting is not excessive. Hence the polar store of fallen snow is well preserved; interior snowfields, ice sheets and glaciers are produced. The commonest form of precipitation is naturally snow, the summer limit of which, in the northern hemisphere, is near the Arctic circle, with the exception of Norway. So far as exploration has yet gone into the highest northern latitudes, rain falls in summer, but probably over most of the Antarctic continent rain never falls. The snow of the polar regions is characteristically fine and dry. At low polar temperatures flakes of snow are not found, but precipitation is in the form of ice spicules. The finest glittering ice needles often fill the air even on clear days, and in calm weather, and, gradually descending to the surface, slowly add to the depth of snow on the ground. Dry snow is also blown from the snowfields on windy days, interfering with the transparency of the air.

Humidity, Cloudiness and Fog.—Absolute humidity is low in polar latitudes, especially in winter, on account of low temperatures. Relative humidity varies greatly, and very low readings have often been recorded. Cloudiness seems to decrease somewhat towards the inner polar areas, after passing the belt of high cloudiness in the higher latitudes of the temperate zones. In marine climates of high latitudes summer has the maximum cloudiness; winter is clearer. The summer maximum is associated with fogs, produced where warm, damp air is chilled by contact with ice. They are also formed over open waters, as among the Faroe islands, for example, and open water spaces, in the midst of an ice-covered sea, are commonly detected at a distance by means of "steam fog." Fogs are less common in winter, when they occur as radiation fogs, of no great thickness. The small winter cloudiness, reported also from the Antarctic zone, corresponds with low absolute humidity and small precipitation. Coasts and islands bathed by warm water of the Gulf Stream drift are usually more cloudy in winter than in summer. The place of fog is in winter taken by fine snow crystals, which often darken the air like fog when strong winds raise the dry snow from the surfaces on which it is lying. Cumulus cloud forms are rare, even in summer. Stratus is probably the commonest cloud of high latitudes, often covering the sky for days without a break.

Physiological Effects.—The north polar summer, in spite of its lack of warmth, is in some respects pleasant and healthful, but the polar night is monotonous, depressing and repelling. Sir W. E. Parry said that it would be difficult to conceive of two things which are more alike than two polar winters. An everlasting uniform snow covering, rigidity, lifelessness and silence—except for the howl of the gale or the cracking of the ice. Small wonder that the polar night has sometimes unbalanced men's minds. The first effects are often a strong desire for sleep and indifference. Later effects have been sleeplessness and nervousness, tending in extreme cases to insanity, anaemia and digestive troubles. Extraordinarily low winter temperatures are easily borne if the air be dry and still. Zero weather seems pleasantly refreshing if clear and calm. But high relative humidity and wind—even a light breeze—give the same degree of cold a penetrating feeling of chill which may be unbearable. Large temperature ranges are endured without danger in the polar winter when the air is dry. Under direct insolation skin burns and blisters; lips swell and crack. Thirst has been much complained of by polar explorers, and is due to the active evaporation from the warm body into the dry, relatively cold air. Polar air is singularly free from micro-organisms owing to lack of communication with other parts; hence many diseases common in temperate zones, "colds" among them, are rare.

Changes of Climate.—The climatic divisions of the world appear to be constant in their broad outlines, but are subject to minor fluctuations which have a duration from a few years up to many centuries. Some known fluctuations of climate have been irregular, but others recur with some regularity. The best known of these meteorological periodicities are the 11-year sunspot

cycle, best shown in the tropics, and the Brückner cycle, of about 35 years, in temperate regions. In the geological past there have been far more extensive changes (see e.g., CLIMATIC HISTORY).

BIBLIOGRAPHY.—Scientific climatology is based upon numerical results, obtained by systematic, long continued, accurate meteorological observations. The essential part of its literature is therefore found in the collection of data published by the various meteorological services. The only comprehensive text-book of climatology is the *Handbuch der Klimatologie* of the late J. von Hann (Stuttgart, 1908-11). The first volume deals with general climatology, and has been translated into English (London and New York, 1903). Reference should be made to this book for further details than are here given. The second and third volumes are devoted to the climates of the different countries of the world. Köppen's *Die Klimate der Erde* and Kendrew's *Climates of the Continents* are valuable reference books. The standard meteorological journal of the world, the *Meteorologische Zeitschrift* (Braunschweig, monthly), is indispensable. The *Quarterly Journal of the Royal Meteorological Society* (London), the *Meteorological Magazine* (London), and the *Monthly Weather Review* (Washington, D. C.) are also valuable. The best collection of charts is that in the *Atlas of Meteorology* (London, 1899) which gives an excellent working bibliography. See also the bibliography issued by the Royal Meteorological Society.

CLIMATE IN THE TREATMENT OF DISEASE.

Broadly speaking, purity of air (*i.e.*, freedom from solid particles and irritating gases), average temperature, range of temperature, amounts of sunshine and of humidity are the most important considerations in the climatic treatment of disease. Social and economic conditions in any given locality are important but are not discussed here. Individuals react both to heat and cold very differently. At health resorts, where the temperature varies between 55° and 70° F., strong individuals gradually lose strength, whereas a delicate person gains vigour of mind and body and puts on weight. And a corresponding intensity of cold acts in the reverse manner in each case. Thus a moderately warm health resort suits delicate, convalescent or elderly people. Cold, however, when combined with wind and damp, must be avoided by the aged, the delicate, and those prone to gouty and rheumatic affections. The moisture of the atmosphere controls the distribution of warmth on the earth, and is closely bound up with the prevailing winds, temperature, light and pressure. In dry air the evaporation from skin and lungs is increased, especially if the sunshine be plentiful and the altitude high. In warm moist air strength is lost and digestive troubles are common. In moist cold air perspiration is checked, and rheumatic and joint affections are common. The main differences between mountain air and that of the plains depend on the former being more rarefied, colder, of a lower absolute humidity, and offering less resistance to the sun's rays. As the altitude is raised, circulation and respiration are quickened, probably as an effort on the part of the organism to compensate for the diminished supply of oxygen, and somewhat more gradually body weight and the number of red blood corpuscles increase, this increase persisting after a return to lower ground. Thus children and young people are especially likely to benefit by the impetus given to growth and the blood-forming organs. For older people, however, the benefit depends on whether their organs of circulation and respiration can respond to the increased demands on them. For anaemia, pulmonary tuberculosis, deficient expansion of the lungs, neurasthenia, and the debility following fevers and malaria, mountain air is invaluable. But where there is valvular disease of the heart, or rapidly advancing disease of the lungs, it is to be avoided. Light, especially direct sunlight, is of primary importance, the lack of it tending to depression and dyspeptic troubles. Indeed, the modern view is that the value of a climate is determined chiefly by the average intensity of ultra-violet light. Probably its germicidal power accounts in part for the aseptic character of the air of the Alps, the desert and other places.

A "good" climate is that in which all the organs and tissues of the body are kept evenly at work in alternation with rest. Thus a climate with constant moderate variations in its principal factors is the best for the maintenance of health. But the best climate for an invalid depends on the particular weakness from which he suffers. Thus in pulmonary tuberculosis a cool sunny climate is greatly superior to a tropical one. Exposure to strong winds is harmful, since it increases cough. A high altitude, from the sunshine, the purity and stimulating properties of the air, is of value

to many mild or very early cases, but where the disease is extensive or the heart is irritable, or there is insomnia, high altitudes are contra-indicated. Where the disease is of long standing, with much expectoration, or accompanied by albuminuria, the patient appears to do best in a humid atmosphere but little above the sea level. The climate of Egypt is suitable for cases complicated with bronchitis or bronchiectasis, but is contra-indicated where there is attendant diarrhoea. Madeira and the Canaries are useful when emphysema is present. Bronchitis in young people is best treated by high altitudes, but in older patients by a moist mild climate, except where much expectoration is present.

Delicate children benefit by residence at the seaside and if very delicate, with small power of reaction, the winter should be passed at some mild coast resort. Gouty and rheumatic affections require a dry soil and warm dry climate, cold and moist winds being especially injurious.

For heart affections high altitudes are to be avoided, though some physicians make an exception of mitral cases where the compensation is good. Moderate elevations of 500 to 1,500ft. are preferable to the sea level.

In diseases of the kidneys, a warm dry climate, by stimulating the action of the skin, lessens the work to be done by these organs, and thus is the most beneficial. Extremes of heat and cold and elevated regions are all to be avoided. (*See HELIOTHERAPY.*)

CLIMATIC HISTORY. The geological history of the earth is divided into five main divisions, Archæan or Pre-Cambrian, Palæozoic, Mesozoic, Tertiary and Quaternary periods (*see GEOLOGY*). These different periods contain evidence of many great changes of climate, but this article is limited to those which have occurred since the appearance of man. The earliest forms of man-like creatures probably appeared towards the close of the Tertiary period, and their development has been greatly influenced by a series of climatic changes which occurred during the Quaternary. The Tertiary is divided into Eocene, Oligocene, Miocene and Pliocene; a fifth stage, the Pleistocene, is now generally included with the Quaternary. The Eocene began 60 million years ago, the Pliocene ended probably 600,000 to a million years ago. At the beginning of the Eocene the climate of middle latitudes was somewhat warmer than it is at present, and in the later Eocene and Oligocene it became very much warmer. Beds of fossil plants of warm temperate aspect dating from these periods have been found north of the Arctic Circle in many regions. In the Miocene the climate was somewhat cooler than in the Oligocene, though probably warmer than the present. At the beginning of Pliocene times, ten to 15 million years ago, the climate of the north temperate regions again became warmer, but this was temporary, and towards the close of this period there was a rapid cooling. This change is well shown in East Anglia, where the earlier Pliocene beds contain mainly southern mollusca, while in the upper part of the Red Crag northern species become increasingly frequent. The later Pliocene beds of East Anglia, the Chillesford beds and Weybourne Crag, contain large numbers of arctic species, and are probably contemporaneous with the first glaciations of Scandinavia and the Alps. The latest bed in this country which was formerly attributed to the Pliocene, the Cromer Forest bed, indicates a return of somewhat warmer conditions; it is succeeded by boulder clays and other deposits of land ice, indicating the oncoming of glacial conditions in England itself. The discovery of Palæolithic implements in this bed indicates, however, that the forest bed and the underlying Weybourne crag should be removed to the Pleistocene. The "Quaternary" Ice age began on the continent of Europe and in North America in the Pliocene, but it is convenient to ignore this somewhat arbitrary division and to consider the Ice Age as a whole.

The Quaternary Ice Age.—The Quaternary or Pleistocene Ice Age was characterized by the advance of great glaciers or ice-sheets from a number of centres, of which the most important were Scandinavia and the Alps in Europe, the Cordilleras and various other centres in North America. Minor centres of glaciation were located in Spitsbergen, Iceland, Ireland, Scotland and northern England, the Pyrenees, the Caucasus Range, the Himalayas, the mountain ranges of central Asia, Alaska and the whole

chain of the Rockies and Andes, the highest mountains of equatorial Africa, south-eastern Australia and New Zealand. The ice-sheets of Greenland and Antarctica are remnants of the Quaternary glaciation, and illustrate the character of the great inland ice-sheets of northern Europe and North America.

Glaciation of the Alps.—The classical work of A. Penck and E. Brückner in the Alpine region has shown that there were four main advances of the glaciers in Central Europe, which they designated Gunz, Mindel, Riss and Wurm. The intervening periods during which the ice retreated (interglacial periods) are termed Gunz-Mindel, Mindel-Riss and Riss-Wurm. In the Gunz glaciation the snow-line probably lay 3,900ft. lower than now, but the remains of this glaciation have been almost entirely obliterated by the later advances. Of the Gunz-Mindel interglacial nothing is known with certainty, but from the amount of erosion performed by the rivers its duration is estimated as 60,000 years. The Mindel glaciation was regarded by Penck and Brückner as the greatest advance of the ice over the eastern half of the Alpine region. The snow-line lay about 4,250ft. below the present. The Mindel-Riss interglacial was very long (about 240,000 years), and for part of the time warmer than the present. The Riss was regarded as the greatest glaciation in the south-west and west, with a snow-line about 4,250ft. below the present. The Riss-Wurm interglacial was relatively short (about 60,000 years), but probably for a time warmer than the present. The Wurm glaciation was considered by Penck and Brückner to have been smaller in extent than the Riss (depression of snow-line 3,900ft.), but the latest worker, W. Soergel, regards it as the greatest glaciation of the Alps. The Wurm was double, the two maxima being separated by a slight retreat. The final retreat of the ice was interrupted by three re-advances, the Bühl, Gschnitz and Daun stages. The interval between the second maximum of the Wurm (Wurm II.) and the Bühl, which is important archaeologically, is termed the Achen oscillation. Penck and Brückner estimated the length of the post-Wurm period as 20,000 years.

Changes of Sea Level.—The changes of sea level during the Quaternary are best known from the work of E. Déperet in the Mediterranean. He recognizes four shore-lines or raised beaches, representing periods when the sea was considerably above its present level. These were separated by periods of land elevation when the sea was below its present level and the Mediterranean was divided into two separate basins.

TABLE 1. *The Divisions of the Quaternary Ice Age (the latest are at the top).*

| Changes of level. | | Glacial stages. | Human Industries. |
|-------------------|--|--|--|
| Monastirian | Upper: Elevation Lower: Submergence to 60ft. | Bühl Re-advance Achen Retreat Wurm Glaciation Riss-Wurm | Magdalenian Solutrean Aurignacian Mousterian Acheulean Evolved Chellean |
| Tyrrhenian | Upper: Elevation Lower: Submergence to roof. | Riss Glaciation Mindel-Riss | Chellean |
| Milazzian | Upper: Elevation Lower: Submergence to 190ft. | Mindel Glaciation Gunz-Mindel | Pre-Chellean |
| Sicilian | Upper: Elevation Lower: Submergence to 330ft. | Gunz Glaciation | |

Glaciation in Northern Europe.—The history of the Scandinavian ice-sheet is not known so fully as that of the Alps. The ice probably formed first on the Norwegian mountains, but the centre soon shifted to Sweden and the Gulf of Bothnia. The ice-sheet extended into Russia, Germany, Denmark and Holland, and at its maximum filled the North Sea and encroached on the east coast of England, especially over East Anglia, where for a time it united with the ice from northern England. The edge of the

ice-sheet over Europe underwent great fluctuations; it is not known with certainty whether it ever completely melted during the whole course of the Quaternary glaciation, but it is highly probable that this happened during at least the Mindel-Riss interglacial. In East Anglia the Scandinavian ice was followed by English ice bearing great quantities of chalk, which formed the Great Chalky Boulder Clay, but the time relations of the various glacial deposits are not yet settled. Gerard de Geer's study of the deposits left by the retreating ice in Sweden has shown that the last ice-sheet began its final retreat about 20,000 years ago. As in the Alps, the retreat of the ice was interrupted by several re-advances, indicated by great terminal moraines (*see below*).

North America.—In North America great ice-sheets reached lower latitudes than anywhere else on the earth. The ice spread out from three main centres, the Cordilleras in the west, the Keewatin west of Hudson's Bay, and Labrador in the east. The deposits of these various centres are complex, but a succession of five glacial and four interglacial stages has been made out in the Mississippi Valley. The latest glaciation, termed the Wisconsin, was double, like the Wurm, and de Geer has succeeded in correlating the stages of its final retreat with those of the last Scandinavian ice-sheet, but the relations of the earlier glacial stages with those in Europe are uncertain. Interglacial beds in Toronto indicate a long period of retreat and perhaps of complete disappearance of the ice, but their position in the Mississippi sequence is uncertain. In most other parts of the world the glaciation has been shown to include three or four advances of the ice, indicating a general similarity with the sequence in the Alps, but direct correlation is not yet possible.

Stages of Human Culture.—The Quaternary Ice Age roughly coincides with the Palaeolithic (*q.v.*) stage of human culture. The various industries into which the Palaeolithic of western Europe is divided are shown in table 1 with their probable positions in the glacial sequence, but there is still some doubt as to the early Palaeolithic. The Magdalenian falls in the period of arctic climate about the Buhl re-advance, while the Solutrean and Aurignacian occupy the Achen oscillation, a period of dry steppe-like climate which followed Wurm II. The whole of the Wurm glaciation (Upper Monastirian) is occupied by the Mousterian, which extends some way back into the Riss-Wurm interglacial (Lower Monastirian), but just how far is not quite settled. The controversy has been concerned chiefly with the position of the Chellean industry, which some assign to the Riss-Wurm, others to the Mindel-Riss interglacial. The correlation in table 1 is a compromise, due to Prof. W. J. Sollas, who places the Chellean proper in the Mindel-Riss (Lower Tyrrhenian) and a later development of it, the "evolved Chellean," in the early part of the Riss-Wurm, while the Acheulean occupies the central and latter parts of that interglacial and the Lower Mousterian its closing stages. The fore-runners of the Chellean types (Pre-Chellean) apparently belong to the Gunz-Mindel interglacial (Lower Milazzian).

Late-Glacial and Post-Glacial Periods.—The climatic history of the concluding stages of the Ice Age is best known from Scandinavia, and thanks to the researches of G. de Geer the various stages have been dated. About 20,000 B.C. the ice-edge lay for a time across Denmark and the Baltic coast of Germany and formed the *Daniglacial* moraine. After a period of retreat, the ice-edge halted again near the coast of the Scandinavian peninsula, where it formed the *Gotiglacial* moraine. The ice then vacated Scania, but there was another long halt about 9000 B.C., forming the great *Fennoscandian* moraines. Up to this time the recession had been comparatively slow, and the edge of the ice had changed but little on the coast of Norway and in northern Finland, while it had everywhere been bordered by a belt of Arctic plants, showing that the temperature was still very low. After the formation of the Fennoscandian moraines, however, there followed a period of very rapid retreat, termed *Finiglacial* time, during which temperate plants occupied almost immediately the ground vacated by the ice, indicating a comparatively high temperature. By about 7000 B.C. the remnants of the ice-sheet had shrunk to a long narrow strip along the centre of Scandinavia. After a short halt termed the *Ragunda* Pause, the ice-sheet split into two sep-

arate portions about 6500 B.C., and this date is regarded by Scandinavian geologists as the "official" end of the Ice Age. The correlation between the stages of retreat in Scandinavia and the Alps is not yet known, but it is not unlikely that the great Fennoscandian moraines represent the Buhl stage.

In Britain various Arctic plant beds are known which were presumably formed during the halts represented by the Gotiglacial and Fennoscandian moraines, and there were local re-advances of mountain glaciers in Scotland at the same times. The retreat stages of other centres of glaciation are not yet known in detail, but de Geer and Ernst Antevs have been able to date parts of the retreat stages of the ice-sheets in Canada and southern Argentina by comparing the relative thicknesses of successive annual clay deposits with those in Sweden.

Changes in Land and Sea Distribution.—As the Scandinavian ice-sheet began to vacate the Baltic basin, the latter was occupied by a fresh-water lake, bounded on the north by the ice. After the formation of the Fennoscandian moraines a subsidence of the land allowed the ingress of the sea, both from the Atlantic across Scania and from the White sea across Finland. The site of the Baltic was now occupied by the Arctic sea, called the *Yoldia sea* from the presence of the high northern mollusc *Yoldia arctica*. About the time of the Ragunda Pause the land rose again and both outlets to the ocean were closed. The Baltic now became a fresh-water lake, which from its characteristic mollusc is termed the *Ancylus* lake. The greater part of the Ancylus lake stage falls in post-glacial time, during which the last remnants of the ice-sheet disappeared. About 4000 B.C. a new period of submergence began in the south-west Baltic, again admitting the waters of the Atlantic and forming the *Littorina sea*. This sea was warmer and more saline than the present Baltic, because the inlet from the Atlantic was wider and deeper. The maximum subsidence probably occurred about 3000 B.C., after which the land gradually rose again and conditions approached those of the present.

A raised beach at a height of about ten ft. above the present beach is found almost all over the world, and in many parts is accompanied by a kind of fauna now known only from lower latitudes. Such a widespread change of level indicates a rise of the sea, due to a greater volume of water in the oceans. The additional water can only have come from a melting back of the still existing ice-sheets, especially of Greenland and Antarctica, beyond their present limits; there is also independent evidence that this occurred. This general warm period is termed the *Climatic Optimum*; it falls somewhere within the time of the Littorina sea and probably between 2000 and 1000 B.C.

Vegetation.—Much information as to late-glacial and post-glacial climates is provided by the vegetation, especially of peat-bogs. In central Europe the Wurm glaciation was accompanied and followed by tundra, which gave place during the latter half of the Achen oscillation to dry cold steppe conditions during which Solutrean man, who hunted the horse, penetrated Europe from the east. In the Lower Magdalenian, the culture of which is based on the reindeer, conditions again became moister and colder, and the tundra returned for a short time, to be rapidly replaced by pine forest spreading up from the south-east. In the Upper Magdalenian the pine began to be replaced by dense forests of oak and the reindeer gave way to the red deer. Dense forests were almost impenetrable to primitive man, and in central Europe there is almost a gap—the "hiatus"—between Palaeolithic and neolithic industries.

In Scandinavia the retreating ice-sheet was bordered by a broad zone of Arctic vegetation until the close of the Fennoscandian halt. The aspen appeared in the much warmer Finiglacial, the fir in the Ancylus period. The very favourable conditions of Littorina time were marked by a wealth of new trees, including oak, hazel and beech; at one time the hazel greatly exceeded its present limits both of latitude and height.

Wet and Dry Periods.—The post-glacial period has had marked alternations of wet and dry climates, which were first set out by the Norwegian Axel Blytt. The time of the Ancylus lake was generally dry, with warm summers but cold winters; Blytt termed this the *Boreal* stage. The early part of Littorina time

was moist, with very mild winters and summers probably as warm as at present, forming the *Atlantic* stage, which was marked by a great growth of peat in northern and western Europe. About 3000 B.C. the warm moist conditions gave way to a dry climate, with very warm summers and winters no colder than the present. The surfaces of the peat-bogs dried up, and in Scandinavia, Scotland and Ireland they were occupied by oak forests; in Germany there is instead a layer of dry heath peat. Blytt terms this the *Sub-Boreal* period. About 850 B.C. there was a marked deterioration of climate, which became moist and cold, forming the *Sub-Atlantic* period, when the forests on the peat-bogs died and were replaced by a new and very rapid growth of peat. The change from the very favourable climate of the Sub-Boreal to the unfavourable climate of the Sub-Atlantic was very marked in the Alps; during the Bronze Age and the beginning of the Early Iron Age the climate was highly favourable and there was free communication across the passes; but early in the Iron Age the passes were closed and human occupation was banished to the lowest and warmest valleys, while at the same time many of the lake-dwellings were submerged. It seems probable that the Daun re-advance of the Alpine glaciers should be attributed to this stage; Penck and Brückner dated the Daun re-advance as older than the Bronze Age, but on very scanty evidence.

The Boreal period is not well shown in the British Isles, but the succession of Atlantic peat, Sub-Boreal forest and Sub-Atlantic peat is well seen in Ireland, most of Scotland and western England but not well developed in eastern England.

Summary.—The various late-glacial and post-glacial stages in Scandinavia may be summarized as follows:

TABLE 2. *Late-glacial and Post-glacial Stages.*

| Date B.C. | Scandinavian Ice Sheet. | Land and Sea. | Trees. | Wet and dry periods. |
|--------------|----------------------------|------------------|-----------------------------|-------------------------|
| 0 | Post- glacial | Littorina Sea | Oak Beech Hazel | Sub-Atlantic |
| 1000 | | | | Sub-Boreal |
| 2000 | | | | |
| 3000 | | Atlantic | | |
| 4000 | | | | |
| 5000 | Ancylos Lake | Fir | Boreal | |
| 6000 | | | | |
| 7000 | Ragunda Pause | Aspen | Sub-Arctic and Arctic | |
| 8000 | Finiglacial Retreat | Yoldia Sea | | |
| 9000 | Fennoscandian Halt | Ice-Lakes | | Arctic Plants |
| 10000 | | | | |

THE HISTORICAL PERIOD

There is no clear boundary between the geological and historical periods, for in Egypt and south-west Asia the beginnings of history are almost contemporary with the end of the Ice Age in Scandinavia. In the arid regions of Arabia, Mesopotamia and central Asia variations of rainfall are of much greater importance than small variations of temperature, and this discussion is accordingly limited to the alternations of wet and dry periods.

Persia.—The semi-arid settlement of Anau on the northern margin of Persia is important. This site was occupied from time to time and abandoned during the intervening periods, and since there is no evidence of conquest, while the periods of abandonment are represented by desert formations, it is highly probable that the interruptions were due to drought. These settlements were investigated by Mr. Raphael Pumpelly, who dated them by means of the relative thickness of deposits. According to Pumpelly's estimates the first settlement began about 9000 B.C., the second, which immediately succeeded it, about 6000 B.C. The last part of the first settlement and the whole of the second show evidence

of gradually increasing drought, and the site was abandoned soon after 6000 B.C. It was reoccupied, after an interval of desert conditions, about 5200 B.C. The third settlement continued until about 2200 B.C., with a short interruption, probably due to drought, about 3000 B.C. These estimates of the age of Anau appear to be far too great, and H. Peake and H. J. Fleure suggest that the first settlement did not begin till about 3000 B.C., while the third settlement lasted from about 2500 to 1600 B.C. At the close of the third period there began a period of intense drought, and Anau was not reoccupied until the Iron Age, probably about 750 B.C.

It is highly probable that in semi-arid regions the amount of unrest and migration increases during periods of drought, so that we can infer the variations of dryness from the frequencies of migrations. A period of extensive migration began about 2650 B.C. and culminated between 2300 and 2050. Another maximum occurred about 1350 to 1300, after which the desert peoples began to settle down, and remained quiet until the Arabian dispersal of the seventh century A.D. (which began before the birth of Mohammed).

Caspian Sea.—During the Christian era our information is mainly derived from the variations of level of the Caspian Sea, amplified and supported by records of other lakes in Asia, and by Chinese archives. There is some doubtful evidence that the level of the Caspian was high about A.D. 0, but this is not confirmed by other sources. In the 5th century A.D. the Caspian was very low. Then follows a period of rapid fluctuations; high level about 920, low about 1125, very high from 1306 to 1325 and again early in the 15th century and about 1560 to 1640.

Africa.—The evidence from northern Africa is mainly provided by the levels of the Nile floods, the history of Kharga Oasis, and the variations in the level of civilization in the Sahara. These point to a rainfall much higher than the present about 500 B.C., a minimum about A.D. 200, a slight improvement about 400, a very dry season from 700 to 1000, and a great improvement from about 1225 to 1300, followed by a decline to present conditions. It is interesting that E. J. Wayland has recently shown the existence of a marked dry period in central Africa in Neolithic times, probably representing the Sub-Boreal period.

America.—In North America the evidence is derived mainly from the width of the annual rings of growth of the "Big Trees" of California; the curve of tree growth can be checked and adjusted by the variations in the levels of the salt lakes of western America, and by archaeological evidence. The result shows that a long dry period ended about 1000 to 800 B.C., followed by a period of high rainfall from 700 B.C. to A.D. 200, reaching a strongly marked maximum at 400 B.C. A long dry period began about A.D. 400 and continued until about 1250, with one break at about 1000, and there was a further dry spell in the 15th century.

In Yucatan and central America the Mayan civilization reached its highest level apparently from 100 B.C. to A.D. 350. After about 350 came the Mayan "Dark Ages," when southern Yucatan relapsed into barbarism. A revival occurred about A.D. 1000, but did not reach the level of the earlier period and probably lasted little more than two centuries. The ruins are now overgrown by dense forests, and Ellsworth Huntington makes the plausible assumption that the periods of high culture represent dry periods. If so, these are contemporaneous with the wet periods of Arizona, and represent a southward swing of all the climatic belts.

Recent excavations in southern Greenland have shown that its climate was far more favourable in the tenth century than it is to-day, and Baffin Bay seems to have been almost free of ice. There was a deterioration about A.D. 1000, followed by a slight improvement during the 11th and 12th centuries, after which the climate rapidly became very bad. The ground, which at first thawed to a considerable depth every summer, became permanently frozen about A.D. 1400.

Sollas, *Ancient Hunters* (3rd ed. 1924).

CLIMAX, JOHN (c. 525–600 A.D.), ascetic and mystic, also called Scholasticus and Sinaïtes. After 40 years in a cave at the foot of mount Sinai, he became abbot of the monastery. His life has been written by Daniel, a monk of the monastery of Raithu, on the Red Sea. He derives his name Climax (or Climacus) from his work of the same name (*Κλίμαξ τοῦ Παπαδέλσου*, ladder to Paradise), in 30 sections, corresponding to the 30 years of life of Christ. It is written in a simple and popular style, and treats of the vices that hinder the attainment of holiness and the Christian virtues.

BIBLIOGRAPHY.—Migne, *Patr. graeca*, lxxxviii. (including the biography by Daniel); see also C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897); Herzog-Hauck, *Realencyklopädie*. The *Ladder* has been translated into several languages—into English by Father Robert, Mount St. Bernard's Abbey, Leicestershire (1856).

CLIMB INDICATOR: see **ALTIMETER**.

CLIMBING BITTERSWEET (*Celastrus scandens*), a North American climbing shrub of the staff-tree family (Celastraceae), called also false bittersweet and waxwork. It grows, mostly in rich soil, from Quebec to Manitoba and southward to North Carolina and New Mexico, usually trailing on banks or small shrubs but sometimes climbing to a height of 25 ft. on trees. It has smooth, pointed leaves and small greenish flowers and matures in autumn showy clusters of orange-yellow, berry-like capsules which split open after frost, disclosing the crimson coverings (arils) enclosing the seeds. The handsome, persistent fruit is used in winter for indoor decoration. (See **BITTERSWEET**.)

CLIMBING FERN, the botanical genus *Lygodium*, with 25 species, chiefly in the warmer parts of the Old World. The plants have a creeping stem, on the upper face of which is borne a row of leaves. Each leaf has a slender, stem-like axis, which twines round a support and bears leaflets at intervals; it goes on growing indefinitely. Several species are favourite greenhouse plants. The American climbing fern (*L. palmatum*), called also Hartford fern and Windsor fern, one of the most beautiful ferns native to the United States, grows in open woods from New Hampshire to Pennsylvania and south to Florida and Tennessee.

CLIM or CLYM OF THE CLOUGH, a legendary English archer, a supposed companion of the Robin Hood band. He is commemorated in the ballad *Adam Bell, Clym of the Cloughe and Wyllyam of Cloudelee*. The three were outlaws who had many adventures of the Robin Hood type. The oldest printed copy of this ballad is dated 1550.

CLINCHANT, JUSTIN (1820–1881), French soldier, was born at Thiaucourt (Meurthe) on Dec. 24, 1820, and died in Paris on March 20, 1881. He entered the army from St. Cyr in 1841. He served in Algeria (1847–52), in the Crimea (1854–55), and in Mexico. He held a brigade command in 1870, was captured at Metz, but escaped, and was placed in command of the 20th Corps of the Army of the East. He was under Bourbaki during the campaign of the Jura, and when Bourbaki attempted to commit suicide he succeeded to the command (Jan. 23, 1871), only to be driven with 84,000 men over the Swiss frontier at Pontarlier. In 1871 Clinchant commanded the 5th Corps operating against the Commune. He was military governor of Paris when he died.

CLINIC, an institution that offers diagnostic, therapeutic or preventive treatment to ambulatory patients. Considered from the standpoint of organization, range of diseases treated, general purpose and function, the term may be used to include outpatient departments of hospitals, unattached units, teaching clinics—either separate or attached—health centres, preventive, curative, public or proprietary institutions. It may also be used to define a particular lecture, classroom or bedside examination where several medical men express their views.

The first dispensary or clinic in the English-speaking world was founded in London in 1696 by philanthropic physicians as a means of providing medicines to accompany the services they made without payment toward the relief of the sick poor. The Philadelphia, New York and Boston Dispensaries, founded in 1786, 1791 and 1796, respectively, had the same object in view. The modern attitude, however, substitutes medical service for medicine and a small payment for actual charity. Johns Hopkins and Massachusetts General Hospital, by establishing outpatient depart-

ments in which their medical students could be taught methods of diagnosis and treatment by personal contact, are believed to be the American pioneers in this form of medical education. As for the public health aspect—the first great movement of this kind resulted in the founding of the National Organization for the Study and Prevention of Tuberculosis in 1905, with the consequent establishment of 500 tuberculosis clinics during the first ten years of its existence. Meanwhile interest in the public welfare has added further clinics, as evidenced by the following figures, available in 1927: In a survey conducted in 83 large cities of the United States it was discovered that 81 had well-baby clinics; 81 had venereal disease clinics; 77 tuberculosis; 68 prenatal and 31 mental clinics—maintained in large part by city health appropriations.

Social service agencies, realizing the important part that illness plays in social maladjustment, have contributed their share in increasing clinic attendance, which jumped from 4,000,000 in 1917 to 10,000,000, in 1927. This increase is largely due to greater efforts for the prevention of disease. Many diseases that in the past were not attended to until they had reached a bed-confining stage can now be diagnosed and cared for in the early stages at clinics, while specialized treatment for various diseases of the skin, eye, nose and throat, and mental, nutritional and postural defects that either were not previously recognized or have come into being as a result of present living and industrial conditions, can be cared for under conditions obtaining at the clinics. In 1925 it was estimated that the number of clinics existing in the United States totalled 5,000, as contrasted with 150 in 1900. In Great Britain the activities outlined above are in the main grouped around the great general hospitals but a few independent dispensaries still exist and have expanded their usefulness.

CLINKER, in industry, the common name for coal residues which are formed in lumps, partly fused, in grates or furnaces. Such clinker is used for many purposes as a raw material, and is a useful matrix for inferior Portland cement concrete. The name is also applied to the fused masses of brick which occur in brick ovens.

What is really a different word, but with the same spelling, is derived from *clinch*, or *clench*, a common Teutonic word, meaning to “fasten together.” This word appears in the form “clinker-built” as distinguished from “carvel-built” for a boat whose strakes overlap and are not fastened “flush.”

CLINOCLASITE, a rare mineral consisting of the basic copper arsenate $(\text{CuOH})_2\text{AsO}_4$. It is deep blue in colour and crystallizes in the monoclinic system with a perfect cleavage parallel to the basal plane; hardness $2\frac{1}{2}$ –3; specific gravity 4.36. The mineral was formerly found with other copper arsenates in the mines of the St. Day district of Cornwall and near Tavistock in Devonshire, near Sayda (or Saida) in Saxony, and in the Tintic district of Utah. It is a mineral of secondary origin, having resulted by the decomposition of copper ores and mispickel in the upper part of mineral veins.

CLINOGRAPH, a set-square the acute angles of which are made adjustable by connecting the side opposite the right-angle to one of the other sides by a hinge; it is frequently employed in mechanical drawing (see **DRAWING**, **ENGINEERING**).

CLINTON, DE WITT (1769–1828), American political leader, was born on March 2, 1769, at Little Britain, N.Y. His father, James Clinton (1736–1812), served as a captain of provincial troops in the French and Indian War, and as a brigadier-general in the American army in the Revolutionary War. De Witt Clinton graduated at Columbia college in 1786, and in 1790 was admitted to the bar. From 1790 to 1795 he was the private secretary of his uncle, George Clinton, governor of New York and a leader of the Republican Party. He entered the State senate in 1798, serving until 1802. He at once became a dominant factor in New York politics, and for the next quarter of a century he played a leading rôle in the history of the commonwealth. From 1801 to 1802 and from 1806 to 1807 he was a member of the council of appointment; and realizing the power this body possessed through its influence over the selection of a vast number of State, county and municipal officers, he secured in 1801, while

his uncle was governor, the removal of a number of Federalist office-holders, in order to strengthen the Republican organization by new appointments. On this account Clinton has generally been regarded as the originator of the "spoils system" in New York; but he was really opposed to the wholesale proscription of opponents that became such a feature of American politics in later years. It was his plan to fill the more important offices with Republicans, as they had been excluded from appointive office during the Federalist ascendancy, and to divide the smaller places between the parties somewhat in accordance with their relative strength. In counties where the Federalists had a majority very few removals were made.

In 1802 Clinton became a member of the U.S. Senate, but resigned in the following year to become mayor of New York city, an office which he held for 10 years in the period 1803-15. During his mayoralty he also held other offices, being a member of the State senate in 1806-11 and lieutenant-governor in 1811-13. In 1812, after a congressional caucus at Washington had nominated Madison for a second term, the Republicans of New York, desiring to break up the so-called Virginia dynasty as well as the system of congressional nominations, nominated Clinton for the presidency by a legislative caucus. Opponents of a second war with Great Britain had revived the Federalist organization, and Federalists from 11 States met in New York and agreed to support Clinton, not on account of his war views, which were not in accord with their own, but as a protest against the policy of Madison. In the election Clinton received 89 electoral votes and Madison 128.

As a member of the legislature Clinton was active in securing the abolition of slavery and of imprisonment for debt, and in perfecting a system of free public schools. In 1810 he was a member of a commission to explore a route for a canal between Lake Erie and the Hudson river, and in 1811 he and Gouverneur Morris were sent to Washington to secure Federal aid for the undertaking, but were unsuccessful. The second war with Great Britain prevented any immediate action by the State; but in 1816 Clinton was active in reviving the project, and a new commission was appointed, of which he became president. His connection with this work so enhanced his popularity that he was chosen governor by an overwhelming majority and served for two triennial terms (1817-23). As governor he devoted his energies to the construction of the canal, but the opposition to his administration, led by Martin Van Buren and Tammany Hall, became so formidable by 1822 that he declined to seek a third term. His successful opponents, however, overreached themselves when in 1824 they removed him from the office of canal commissioner. This partisan action aroused such indignation that at the next election he was again chosen governor, by a large majority, and served from 1825 until his death. As governor he took part in the formal ceremony of admitting the waters of Lake Erie into the canal in Oct. 1825, and thus witnessed the completion of a work which owed more to him than to any other man. Clinton died at Albany, N.Y., on Feb. 11, 1828. In addition to his interest in politics and public improvements, he devoted much study to the natural sciences; among his published works are a *Memoir on the Antiquities of Western New York* (1818) and *Letters on the Natural History and Internal Resources of New York* (1822).

McBain's *De Witt Clinton and the Origin of the Spoils System in New York* (1907); T. E. Benedict, "De Witt Clinton's Birthplace," *Olde Ulster*, vol. vii, pp. 65-69 (1911); and E. A. Fitzpatrick, "The Educational Views and Influence of De Witt Clinton," *Teachers College, Columbia University Contributions to Education*, No. 44 (1911).

CLINTON, GEORGE (1739-1812), American soldier and political leader, was born at Little Britain, Ulster (now Orange) county (N.Y.), on July 26, 1739, the son of Charles Clinton (1690-1773), who had emigrated to America in 1729, and commanded a regiment of provincial troops in the French and Indian War. The son went to sea at the age of 16, but, finding the sailor's life distasteful, joined his father's regiment and accompanied him as lieutenant in the expedition against Fort Frontenac in 1758. After the war he practised law and held a number of minor civil

offices in Ulster county. From 1768 to 1775 he sat in the New York provincial assembly, and in the controversies with Great Britain zealously championed the colonial cause. In 1774 he was a member of the New York committee of correspondence, and in 1775 was a member of the second Continental Congress. In December of this year he was appointed a brigadier-general of militia by the New York provincial congress. In the following summer, being ordered by Washington to assist in the defence of New York, he left Philadelphia, after voting for the Declaration of Independence, and before he could sign it.

General Clinton took part in the battle of White Plains (Oct. 28, 1776), and was charged with the defence of the highlands of the Hudson, where, with De Witt Clinton, in Oct. 1777, he offered a firm but unsuccessful resistance to the advance of Sir Henry Clinton. In March of this year he had been appointed by Congress a brigadier-general in the continental army, and he thus held two commissions, as the State convention refused to accept his resignation as brigadier-general of militia. So great was Clinton's popularity at this time that at the first election under the new State constitution he was chosen both governor and lieutenant-governor. He declined the latter office, and on July 30, 1777, entered upon his duties as governor, which were at first largely of a military nature. In 1780 he took the field and checked the advance of Sir John Johnson and the Indians in the Mohawk valley. In his administration Clinton was energetic and patriotic, and though not so intellectual as some of his New York contemporaries, he was more popular than any of them. He served as governor for 18 successive years (1777-95), and for another triennial term from 1801 to 1804. In the elections of 1780, 1783, and 1786 he had no opponent. In 1800-01 he was a member of the assembly.

In the struggle in New York over the adoption of the Federal constitution he was one of the leaders of the opposition, but in the State convention of 1788, over which he presided, his party was defeated and the constitution was ratified. In national politics he was a follower of Thomas Jefferson, and in State politics he led the long dominant faction known as "Clintonians." In 1789, 1792, and 1796 Clinton received a number of votes in the electoral college but not enough to secure him the vice-presidency, which was then awarded to the recipient of the second highest number of votes. In 1804, however, after the method of voting had been changed, he was nominated for the vice-presidency by a congressional caucus, and was duly elected. In 1808 he sought nomination for the presidency and was greatly disappointed when this went to Madison. He was again chosen as vice-president, however, and died in Washington before the expiration of his term, on April 20, 1812. He was buried in the congressional cemetery, from which in May, 1908, his remains were transferred to Kingston (N.Y.). His casting vote in the Senate in 1811 defeated the bill for the renewal of the charter of the Bank of the United States.

The *Public Papers of George Clinton*, 6 vols. (1899-1902) have been published by the State of New York. See also St. S. Spaulding, *George Clinton and the New York Democracy* (Harvard University, 1926).

CLINTON, SIR HENRY (c. 1738-1795), British general, was the son of Admiral George Clinton (governor of Newfoundland and subsequently of New York), and grandson of the 6th earl of Lincoln. After serving in the New York militia, he came to England and joined the Coldstream Guards. In 1758 he became captain and lieutenant-colonel in the Grenadier Guards, and in 1760-62 served as aide-de-camp to Ferdinand of Brunswick in the Seven Years' War. He became major-general in 1772. From 1772 to 1784, thanks to the influence of his cousin, the 2nd duke of Newcastle, he had a seat in parliament, first for Boroughbridge and subsequently for Newark, but for the greater part of this time he was on active service in America in the War of Independence. He took part in the battles of Bunker Hill and Long Island, subsequently taking possession of New York. For his share in the battle of Long Island he was made a lieutenant-general and K.B. After Saratoga he succeeded Sir William Howe as commander-in-chief in North America. He had already been made a

local general. He at once concentrated the British forces at New York, pursuing a policy of foraying expeditions in place of regular campaigns. In 1779 he invaded South Carolina, and in 1780 in conjunction with Admiral M. Arbuthnot captured Charleston. There was constant friction between him and Lord Cornwallis, his second in command, and in 1782, after the capitulation of Cornwallis at Yorktown, he was superseded by Sir Guy Carleton. Returning to England, he published in 1783 his *Narrative of the Campaign of 1781 in North America*, which provoked an acrimonious reply from Lord Cornwallis. He was elected M.P. for Launceston in 1790, and in 1794 was made governor of Gibraltar, where he died on Dec. 23, 1795.

His younger son, SIR HENRY CLINTON (1771-1829), entered the army in 1787 and saw some service with the Prussians in Holland in 1789. He was almost continuously in active service; in the Corunna campaign of 1808-9, he was adjutant-general to his close friend, Sir John Moore. Promoted major-general in 1810, he returned to the Peninsula to fill a divisional command under Wellington in 1811. His division played a notable part in the capture of the forts at Salamanca and in the battle of Salamanca (1812), and he was given the local rank of lieutenant-general early in 1813. For his conduct at Vittoria he was made a K.B., and he took his part in the subsequent victories of the Nive, Orthes and Toulouse. At the end of the war he was made a lieutenant-general and inspector-general of infantry. Clinton commanded a division with distinction at Waterloo. He died on Dec. 11, 1829.

CLINTON, HENRY FYNES (1781-1852), British classical scholar and chronologist, was born at Gamston in Nottinghamshire. He was educated at Westminster and Oxford, and from 1806 to 1826 was M.P. for Aldborough. The value of his *Fasti*, which set classical chronology on a scientific basis, can scarcely be over-estimated, even though subsequent research has corrected some of his conclusions.

His chief works are: *Fasti Hellenici, the Civil and Literary Chronology of Greece from the 55th to the 124th Olympiad* (1824-51), including dissertations on points of Greek history and Scriptural chronology; and *Fasti Romani, the Civil and Literary Chronology of Rome and Constantinople from the Death of Augustus to the Death of Heraclius* (1845-50). In 1851 and 1853 respectively he published epitomes of the above. *The Literary Remains of H. F. Clinton* (the first part of which contains an autobiography written in 1818) were edited by C. J. F. Clinton in 1854.

CLINTON, a city of Illinois, U.S.A., on Federal highway 51 and the Illinois Central railroad, 22m. S. of Bloomington; the county seat of De Witt county. The population in 1930 was 5,920. It is in the heart of the corn belt; and has railroad shops and clothing factories. It was settled about 1836, and was incorporated as a city in 1855.

CLINTON, a city of Vermilion county, Indiana, U.S.A., on the Wabash river, 15m. N. of Terre Haute and 8m. E. of the Illinois State line. It is 1m. from Federal highway 41, and is served by the Chicago and Eastern Illinois railway. In 1900 the population was 2,918; in 1920, 10,962; in 1930 it was 7,936. Clinton is in a farming and coal-mining region, and has varied manufactures, including mining and agricultural machinery, meat and dairy products, sauces and relishes, vaults and other articles of cement, flour, overalls, furniture, and blasting powder. The assessed valuation of property in 1926 was \$7,166,899. The county hospital is located there. Clinton was incorporated as a city in 1893.

CLINTON, a city in the extreme eastern part of Iowa, U.S.A., on the Mississippi river where the Lincoln highway crosses it; the county seat of Clinton county. It is on the Burlington, the Chicago and North Western, the Chicago, Milwaukee, St. Paul and Pacific, the Rock Island, the Clinton, Davenport and Muscatine, and the Davenport, Rock Island and Northwestern railways. The population in 1920 was 24,151, of whom 3,739 were foreign-born white (1,573 Germans); and in 1930, Federal census 25,726. The city lies about 600ft. above sea-level, and has a background of hills to the west and rocky bluffs to the north. Part of the river front is developed as a public park. The streets are shaded with magnificent trees, and there are many beautiful old residences (some of them now used by civic organizations) built

by the saw-mill millionaires when Clinton was a great lumbering town. At present it is a manufacturing and jobbing centre of importance, with an annual factory output valued at \$30,000,000 and bank deposits amounting to over \$18,000,000. There is a large corn-syrup refinery. Among the other manufactures are furniture, sash and doors, locks, wire screen, boilers and tanks, mail cranes, steel bridges, and structural iron work. Clinton was founded in 1855 by the Iowa Land company. It took the name of the county, which was called after De Witt Clinton.

CLINTON, a town of Worcester county, Massachusetts, U.S.A., on the Nashua river, 15m. N.N.E. of Worcester. It is served by the Boston and Maine and the New York, New Haven and Hartford railways. The population in 1920 was 12,979 (32% foreign-born white); in 1930 (Federal census) 12,817.

The town contains 78q.m. of varied and picturesque hilly country, with charming scenery along the river. In its south-west corner, on the southern branch of the Nashua river, is part of the Wachusett dam and reservoir of the water-supply system of the Boston metropolitan area. There are extensive manufactures, with an output in 1925 valued at \$19,966,936. In 1813 cotton cloth was produced there under the factory system, but the first modern textile mill was established in 1838, for making coach-lace. The industrial importance of the town is due largely to Erastus Brigham Bigelow (1814-79), inventor of power-looms which revolutionized the manufacture of figured fabrics, and of a loom for weaving wire-cloth. In 1843, with his brother Horatio M. Bigelow, he established in Clinton the Lancaster Mills for the manufacture of gingham, and about ten years later, the Bigelow Carpet Mills. The Roubaix Mills also (making fine velours) are located here.

Clinton was settled in 1645, and was separated from Lancaster as an independent town in 1850.

CLINTON, a city of Missouri, U.S.A., on the Grand river, 87m. S.E. of Kansas City; the county seat of Henry county. It is served by the Frisco and the Missouri-Kansas-Texas railways. The population in 1930 was 5,744. The city lies at the edge of a rolling prairie, 770ft. above sea-level. It is the trade centre for an agricultural and stock-raising district and has large flour mills. Considerable coal is mined in the county. Clinton was laid out in 1836 and incorporated in 1865.

CLINTON, a village of Oneida county, N.Y., U.S.A., 9m. S.W. of Utica, on Oriskany creek and the New York, Ontario and Western railway. The population in 1930 Federal census was 1,475. There are mineral springs and iron mines in the vicinity, and the village has knitting and paint mills and vegetable canneries. Many business men of Utica make it their home. It is the seat of Hamilton college for men (opened as an academy in 1798 and chartered as a college in 1812), which was founded by Samuel Kirkland (1741-1808), a missionary among the Oneida Indians, and named after Alexander Hamilton. Its corner stone was laid by Baron von Steuben; and its shade-trees were presented by Thomas Jefferson. Litchfield observatory, connected with the college, was long in charge of C.H.F. Peters, who there discovered over 40 asteroids and made extensive investigations concerning comets. The village, settled about 1786 by pioneers from New England, was named after George Clinton, and was incorporated in 1843. It was the birthplace, and is the summer home, of Elihu Root.

CLINTONIA, a genus of beautiful herbs of the lily family (Liliaceae), named in honour of De Witt Clinton (1769-1828), governor of the State of New York. There are 6 species, 4 North American and 2 Asian, all stemless perennials, with a few broad leaves rising from a slender rootstock, and lilylike flowers, usually borne in clusters (umbels) at the top of the flower stalk (scape). The yellow clintonia (*C. borealis*) is found in woods from Newfoundland to Manitoba and southward to North Carolina and Wisconsin; the white clintonia (*C. umbellulata*) occurs in woods from New York and New Jersey to Tennessee and Georgia; the mountain clintonia (*C. uniflora*), with a single white flower, grows from Montana and California northward to Alaska; the western clintonia (*C. andrewsiana*) is found near the Pacific coast in central California.

CLINTONITE: see OTTRELITE.

CLIPPER SHIPS, a class of sailing vessel developed principally by American ship-builders during the first half of the 19th century. The origin of the word clipper is not definitely known. Some authors think that the expression "going at a clip" might have been responsible for it, while others have traced the word to the poets Shelley and Burns. The first large ship of the kind was the "Ann McKim" (494 tons), built in Baltimore in 1833; but smaller vessels of similar construction were already well known as "Baltimore clippers." The gold rush in California, which gave such impetus to the building of these ships, was responsible for the launching of 160 clipper ships within 4 years, during the first of which 90,000 passengers were carried; while the discovery of gold in Australia soon after caused 400,000 people to be transported to that country in British-owned clippers. The Bell, Hall, Steers, Webb, Collier, McKay and Magoun are some of the American families who built clipper ships, and the Osgood, Marshall, Trask, Woodhouse, Delano, DePuyster and Russell families had among their members many captains of these vessels. The type was abandoned by American builders after 1854, when freight rates dropped, and since the American clippers were built of oak or other expensive hardwoods, it was no longer profitable to construct them. Subsequently, for more than a decade, a modified ship known as the "medium clipper" was developed. Its speed, however, never equalled that of the original, or "extreme clipper," which might make as much as 18 knots. Typically, the extreme clipper was a long, slender vessel, with a sharp, long bow and with the three masts slanting backwards and carrying rectangular sails. In small vessels, these characteristics of narrow beam and great sail-carrying capacity had been developed by American builders before 1812. The invention of the type, however, was not American; it was an adaptation of principles that had been carefully studied by French scientists during the 18th century and accepted by the builders of French war vessels, which were then the fastest afloat. The majority of the clippers were built in New England yards, and their usual run was between ports of the eastern American seaboard and China, Australia or San Francisco. But the career of the famous "Nightingale," from the time of its launching in 1851 until its loss in 1893, shows a variety of voyages to every part of the world. The equally well known "Witch of the Wave" had a similar record, although shorter by some 20 years.

Besides the Californian and Australian gold rushes and the opium and slave trades, which gave such impetus to the building of clipper ships, one of the most potent motives for speed by water in the early nineteenth century was furnished by the Chinese tea trade. Inasmuch as this commodity quickly loses its flavour in the hold of a ship, annual prizes were offered by London merchants for the delivery at the earliest possible moment of the first crop of the season. Public excitement ran high, and rivalry among the various ships in the annual race from China was keen. One of these, the "Cutty Sark," built in 1869 and still afloat in 1928, covered 363m. in a day's travel, the record for tea clippers. By 1872, due to the opening of the Suez Canal in 1870 which shortened the route to the East, aided further by the greater improvement in and more extended use of steam-propelled boats, these romantically interesting tea races had virtually passed out of existence. With her hull picturesquely painted in bands of white and black, and dummy portholes in black, with her great number of sails and long, sharp bow the clipper ship of the nineteenth century was "the ideal of applied art and a sheer delight to the eye"—the possessor of "that peculiarly satisfying beauty which always belongs to the thing absolutely fitted for the purpose it is designed to fill." An excellent account has been compiled by Octavius T. Howe and Frederick C. Matthews, *American Clipper Ships 1833-58* (1926-27) published by the Marine Research Society at Salem.

CLISSON, OLIVIER DE (1336-1407), French soldier, was the son of Olivier de Clisson who was put to death in 1343 on the suspicion of having wished to give up Nantes to the English. He was brought up in England, where his mother, Jeanne de Belleville, had married her second husband. On his return to Brittany he took arms on the side of de Montfort, distinguishing himself

at the battle of Auray (1364), but in consequence of differences with Duke John IV. went over to the side of Blois. In 1370 he joined Bertrand du Guesclin, who had lately become constable of France, and followed him in all his campaigns against the English. On the death of du Guesclin Clisson received the constable's sword (1380). He fought with the citizens of Ghent, defeating them at Roosebeke (1382), later on commanded the army in Poitou and Flanders (1389), and made an unsuccessful attempt to invade England. On his return to Paris, in 1392, an attempt was made to assassinate him by Pierre de Craon, at the instigation of John IV. of Brittany. In order to punish the latter Charles VI., accompanied by the constable, marched on Brittany, but it was on this expedition that the king was seized with madness. The uncles of Charles VI. took proceedings against Clisson, so that he had to take refuge in Brittany. He was reconciled with John IV., and after the duke's death, in 1399, he became protector of the duchy, and guardian of the young princes. He had gathered vast wealth before his death on April 23, 1407.

CLISSON, a town of western France, in the department of Loire-Inférieure, 17 m. S.E. of Nantes, at the confluence of the Sèvre and the Moine, both of which are crossed by old bridges. Pop. (1926) 2,222. The town gave its name to the celebrated family of Clisson, of which the most famous member was Olivier de Clisson. It has the imposing ruins of their stronghold, parts of which date from the 13th century. The town and castle were destroyed in 1792 and 1793 during the Vendean wars, but the town was rebuilt shortly afterwards.

CLITHEROE, municipal borough, north-east Lancashire, England, 35 m. N. by W. from Manchester, on the L.M.S.R. Pop. (1931) 12,008. It is finely situated in the valley of the Ribble, at the foot of Pendle Hill, a steep plateau-like mass rising to 1,831 feet.

The Honour of Clitheroe (Clyderhow or Cletherwoode) was first held by Roger de Poitou, almost certainly the builder of the castle. He granted it to Robert de Lacy, and it passed by marriage to Thomas, earl of Lancaster, in 1310. It was part of the duchy of Lancaster till Charles II. bestowed it on General Monk, from whose family it descended through the house of Montague to that of Buccleuch. The first charter was granted about 1283 to the burgesses by Henry de Lacy, confirming the liberties granted by the first Henry de Lacy. The 1283 charter was confirmed by Edward III., Henry V., Henry VIII. and James I. Fairs, on Dec. 7 to 9 and March 24 to 26 are held under a charter of Henry IV. A weekly market has been held on Saturday since William I.'s days. The church of St. Mary Magdalene, though occupying an ancient site, is modern. The town has a grammar school, founded in 1554, and a technical school. On a height commanding the valley stands the keep and other fragments of the Norman castle but part of the site is occupied by a modern mansion. A large percentage of the population is engaged in the textile industry. In 1558 the borough was granted two members of parliament, and continued to return them till 1832, when the number was reduced to one. In 1885 the borough was disfranchised and is now represented in the Clitheroe Division of Lancashire. Area 2,386 acres.

Stonyhurst College, 5 m. S.W. of Clitheroe, is a college for Roman Catholic students. The nucleus of the buildings is a mansion (17th century) given by Thomas Weld in 1795 to refugee Jesuits from the continent. An observatory is attached to the college.

CLITUMNUS, a river in Umbria, Italy, rising from an abundant spring by the road between the ancient Spoletium and Trebia, 8m. from the former, 4m. from the latter. After a short course through the territory of Trebia it joins the Tinea, a tributary of the Tiber. Pliny described and Caligula and Honorius visited the lake, which is still a clear pool surrounded by poplars and weeping willows. The stream was personified as a god, whose ancient temple lay near the spring; close by were other smaller shrines and it occurs under the name *Sacraria* (the shrines) as a Roman post station. The building, generally known as the Tempio di Clitumno, close to the spring, is an ancient Christian chapel, its decorative sculptures being contemporary with those of S. Salvatore at Spoleto (4th century).

CLIVE, ROBERT CLIVE, BARON (1725-1774), the statesman and general who founded the empire of British India, was born on Sept. 29, 1725, at Styche, the family estate, in the parish of Moreton Say, Market Drayton, Shropshire. The Clives, or Clyves, were one of the oldest families in the county of Shropshire, having held the manor of that name in the reign of Henry II. One Clive was Irish chancellor of the exchequer under Henry VIII.; another was a member of the Long Parliament; Robert's father for many years represented Montgomeryshire in parliament.

Young Clive was the despair of his teachers. Sent from school to school, and for only a short time at the Merchant Taylors' school, he neglected his books for perilous adventures. But he could read Horace in after life; and he must have laid in his youth the foundation of that clear and vigorous English style which marked all his despatches, and made Lord Chatham declare of one of his speeches in the House of Commons that it was the most eloquent he had ever heard. At 18 he was sent out to Madras as a "factor" or "writer" in the civil service of the East India Company. For the first two years of his residence he felt keenly the separation from home; he was always breaking through the restraints imposed on young "writers"; and he was rarely out of trouble with his fellows, with one of whom he fought a duel. His one solace was found in the governor's library, where he sought to make up for past carelessness by a systematic course of study. He was just of age, when in 1746 Madras was forced to capitulate to Labourdonnais during the War of the Austrian Succession. The breach of that capitulation by Dupleix, then at the head of the French settlements in India, led Clive, with others, to escape from the town to the subordinate Fort St. David, some 20m. to the south. There Clive obtained an ensign's commission.

At this time India was ready to become the prize of the first conqueror who combined administrative with military skill. For the 40 years since the death of the emperor Aurangzeb, the power of the Great Mogul had gradually fallen into the hands of his provincial viceroys or *subadars*. The three greatest of these were the nawab of the Deccan, or south and central India, who ruled from Hyderabad, the nawab of Bengal, whose capital was Murshidabad, and the nawab or wazir of Oudh. The prize lay between Dupleix, who had the genius of an administrator, or rather intriguer, but was no soldier, and Clive, the first of a century's brilliant succession of those "soldier-politicals" to whom Great Britain owed the conquest and consolidation of India. Clive successively established British ascendancy against French influence in the three great provinces under these nawabs. But his merit lies especially in the ability and foresight with which he secured the richest of the three, Bengal. But Clive had hardly been able to commend himself to Maj. Stringer Lawrence, the commander of the British troops in Madras and the Deccan, by his courage and skill in several small engagements, when the peace of Aix-la-Chapelle (1748) forced him to return to his civil duties for a short time. An attack of fever which severely affected his spirits led him to visit Bengal. On his return he found a contest going on between two sets of rival claimants for the position of viceroy of the Deccan, and for that of nawab of the Carnatic, the greatest of the subordinate States under the Deccan. Dupleix, who took the part of the pretenders to power in both places, was carrying all before him. The British had been weakened by the withdrawal of a large force under Admiral Boscawen, and by the return home, on leave, of Maj. Lawrence. But that officer had appointed Clive commissary for the supply of the troops with provisions, with the rank of captain. More than one disaster had taken place on a small scale, when Clive drew up a plan for dividing the enemy's forces, and offered to carry it out himself. The pretender, Chandar Sahib, had been made Nawab of the Carnatic with Dupleix's assistance, while the British had taken up the cause of the more legitimate successor, Mohammed Ali. Chandar Sahib had left Arcot, the capital of the Carnatic, to reduce Trichinopoly, then held by a weak English battalion. Clive offered to attack Arcot in order to force Chandar Sahib to raise the siege of Trichinopoly. But Madras and Fort St. David could supply him with only 200 Europeans and 300 sepoys. Of the eight officers

who led them, four were civilians like Clive himself, and six had never been in action. His force had but three field-pieces. The circumstance that Clive, at the head of this handful, had been seen marching during a storm of thunder and lightning, frightened the enemy into evacuating the fort, which the British at once began to strengthen against a siege. Clive treated the great population of the city with so much consideration that they helped him to make successful sallies against the enemy. As the days passed on, Chandar Sahib sent a large army under his son and his French supporters, who entered Arcot and closely besieged Clive in the citadel. The story of the gallant defence of the citadel and of the repulse of the enemy is told in Macaulay's famous essay on Clive.

In India there is no parallel to the defence of the citadel of Arcot in 1751 till we come to the siege of Lucknow in 1857. Clive, now reinforced, followed up his advantage, and Maj. Lawrence returned in time to carry the war to a successful issue. In 1754 the first of the Carnatic treaties was made provisionally, between T. Saunders, the company's resident at Madras, and M. Godeheu, the French commander, in which the British protégé, Mohammed Ali, was virtually recognized as nawab, and both nations agreed to equalize their possessions. When war again broke out in 1756, and the French, during Clive's absence in Bengal, obtained successes in the northern districts, his efforts helped to drive them from their settlements. The Treaty of Paris in 1763 formally confirmed Mohammed Ali in the position which Clive had won for him. Two years after, the Madras work of Clive was completed by a firman from the emperor of Delhi, recognizing the British possessions in southern India.

The siege of Arcot at once gave Clive a European reputation. Pitt pronounced the youth of 27 who had done such deeds a "heaven-born general." When the court of directors voted him a sword worth £700, he refused to receive it unless Lawrence was similarly honoured. He left Madras for home, after ten years' absence, early in 1753. Before leaving India he married Margaret Maskelyne. The marriage was a happy one, and the scandalous stories of his private life spread later by his enemies are devoid of foundation. After he had been two years at home the state of affairs in India made the directors anxious for his return. He was sent out, in 1756, as governor of Fort St. David, with the reversion of the Government of Madras, and with the commission of Lieutenant-colonel in the king's army. He took Bombay on his way, and there commanded the land force which captured Gheria, the stronghold of the Mahratta pirate, Angria. He took his seat as governor of Fort St. David on the day on which the nawab of Bengal captured Calcutta, and thither the Madras Government at once sent him, with Admiral Watson. He entered on the second period of his career.

Since, in Aug. 1690, Job Charnock had landed at the village of Sutanati with a guard of one officer and 30 men, the infant capital of Calcutta had become a rich centre of trade. The successive nawabs or viceroys of Bengal had been friendly to it, till, in 1756, Suraj-ud-Dowlah succeeded his uncle at Murshidabad. His predecessor's financial minister had fled to Calcutta to escape the extortion of the new nawab, and the English governor refused to deliver up the refugee. Enraged at this, Suraj-ud-Dowlah captured the old fort of Calcutta on June 20, and plundered it. Many of the English fled to ships and dropped down the river. The 146 who remained were forced into "the Black Hole" in the stifling heat of the sultriest period of the year. Only 23 came out alive. The fleet was as strong, for those days, as the land force was weak. Disembarking his troops some miles below the city, Clive marched through the jungles, where he lost his way owing to the treachery of his guides, but soon invested Fort William, while the fire of the ships reduced it, on Jan. 2, 1757. On Feb. 4, he defeated the whole army of the nawab, which had taken up a strong position just beyond what is now the most northerly suburb of Calcutta. The nawab hastened to conclude a treaty, under which favourable terms were conceded to the company's trade, the factories and plundered property were restored, and an English mint was established. In the accompanying agreement, offensive and defensive, Clive appears under the name by which he was always known

to the natives of India, Sabut Jung, or "the daring in war." With 600 British soldiers, 800 sepoys, seven field-pieces and 500 sailors to draw them, he had routed a force of 34,000 men with 40 pieces of heavy cannon and 50 elephants, and had seized a camp four miles in length.

In spite of his double defeat and the treaty which followed it, the madness of the nawab burst forth again. As England and France were once more at war, Clive sent the fleet up the river against Chandernagore, while he besieged it by land. After consenting to the siege, the nawab sought to assist the French, but in vain. The capture of their principal settlement in India, next to Pondicherry, which had fallen in the previous war, gave the combined forces prize to the value of £130,000. The rule of Suraj-ud-Dowlah became as intolerable to his own people as to the British. They formed a confederacy to depose him, at the head of which was Jafar Ali Khan, his commander-in-chief. Associating with himself Admiral Watson, Governor Drake and Mr. Watts, Clive made a treaty in which it was agreed to give the office of viceroy of Bengal, Behar and Orissa to Jafar, who was to pay a million sterling to the company for its losses in Calcutta and the cost of its troops, half a million to the British inhabitants of Calcutta, £200,000 to the native inhabitants, and £70,000 to its Armenian merchants. Up to this point all is clear. Suraj-ud-Dowlah was hopeless as a ruler. His relations alike to his master, the merely titular emperor of Delhi, and to the people left the province open to the strongest. After "the Black Hole," the battle of Calcutta, and the treachery at Chandernagore, in spite of the treaty which followed that battle, the East India Company could treat the nawab only as an enemy. Clive, it is true, might have disregarded all native intrigue, marched on Murshidabad, and at once held the delta of the Ganges in the company's name. But the time was not ripe for this, and the consequences, with so small a force, might have been fatal. The idea of acting directly as rulers, or save under native charters and names, was not developed by events for half a century. The political morality of the time in Europe, as well as the comparative weakness of the company in India, led Clive not only to meet the dishonesty of his native associate by equal dishonesty, but to justify his conduct by the declaration, years after, in parliament, that he would do the same again. It became necessary to employ the richest Bengali trader, Omichund, as an agent between Jafar Ali and the British officials. Master of the secret of the confederacy against Suraj-ud-Dowlah, the Bengali threatened to betray it unless he was guaranteed, in the treaty itself, £300,000. To dupe the villain, who was really paid by both sides, a second, or fictitious treaty, was shown him with a clause to this effect. This Admiral Watson refused to sign; "but," Clive deposed to the House of Commons, "to the best of his remembrance, he gave the gentleman who carried it leave to sign his name upon it; his lordship never made any secret of it; he thinks it warrantable in such a case, and would do it again a hundred times; he had no interested motive in doing it, and did it with a design of disappointing the expectations of a rapacious man." Such is Clive's own defence of the one act which, in a long career of abounding temptations, was of questionable honesty.

The whole hot season of 1757 was spent in these negotiations, till the middle of June, when Clive began his march from Chandernagore, the British in boats, and the sepoys along the right bank of the Hugli. That river above Calcutta is, during the rainy season, fed by the overflow of the Ganges to the north through three streams, which in the hot months are nearly dry. On the left bank of the Bhagirathi, the most westerly of these, room above Chandernagore, stands Murshidabad, the capital of the Mogul viceroys of Bengal, and then so vast that Clive compared it to the London of his day. Some miles farther down is the field of Plassey, then an extensive grove of mango trees. On June 21, Clive arrived on the bank opposite Plassey, in the midst of that outburst of rain which ushers in the south-west monsoon of India. His whole army amounted to 1,100 Europeans and 2,100 native troops, with nine field-pieces. The nawab had drawn up 18,000 horse, 50,000 foot and 53 pieces of heavy ordnance, served by French artillerymen. For once in his career Clive hesitated, and

called a council of 16 officers to decide, as he put it, "whether in our present situation, without assistance, and on our own bottom, it would be prudent to attack the nawab, or whether we should wait till joined by some country power?" Clive himself headed the nine who voted for delay; Major (afterwards Sir) Eyre Coote led the seven who counselled immediate attack. But, either because his daring asserted itself, or because also, of a letter that he received from Jafar Ali, as has been said, Clive was the first to change his mind and to communicate with Major Eyre Coote. One tradition, followed by Macaulay, represents him as spending an hour in thought under the shade of some trees, while he resolved the issues of what was to prove one of the decisive battles of the world. Another, turned into verse by Sir Alfred Lyall, pictures his resolution as the result of a dream. However, that may be, he did well as a soldier to trust to the dash and even rashness that had gained Arcot and triumphed at Calcutta, and as a statesman, since retreat, or even delay, would have put back the conquest of India for years. When, after the heavy rain, the sun rose brightly on the 22nd, the 3,200 men and the nine guns crossed the river and took possession of the grove and its tanks of water, while Clive established his headquarters in a hunting lodge. On the 23rd the engagement took place and lasted the whole day. Except the 40 Frenchmen and the guns which they worked, the enemy did little to reply to the British cannonade which, with the 39th Regiment, scattered the host, inflicting on it a loss of 500 men. Clive restrained the ardour of Maj. Kilpatrick, for he trusted to Jafar Ali's abstinence, if not desertion to his ranks, and knew the importance of sparing his own small force. He lost hardly a white soldier; in all 22 sepoys were killed and 50 wounded. Suraj-ud-Dowlah fled from the field on a camel, secured what wealth he could, and came to an untimely end. Clive entered Murshidabad, and established Jafar Ali in the position which his descendants have since enjoyed, as pensioners, but have not infrequently abused. When taken through the treasury, amid a million and a half sterling's worth of rupees, gold and silver plate, jewels and rich goods, and besought to ask what he would, Clive was content with £160,000, while half a million was distributed among the army and navy, both in addition to gifts of £24,000 to each member of the company's committee, and besides the public compensation stipulated for in the treaty. It was to this occasion that he referred in his defence before the House of Commons, when he declared that he marvelled at his moderation. He followed a usage fully recognized by the company, although the fruitful source of future evils which he himself was again sent out to correct. The company itself acquired a revenue of £100,000 a year, and a contribution towards its losses and military expenditure of a million and a half sterling. Jafar Ali afterwards presented Clive with the quit-rent of the company's lands in and around Calcutta, amounting to an annuity of £27,000 for life, and left him by will the sum of £70,000 which Clive devoted to the army.

While busy with the civil administration, the conqueror of Plassey followed up his military success. He sent Maj. Coote in pursuit of the French almost as far as Benares. He despatched Col. Forde to Vizagapatam and the northern districts of Madras, where that officer gained the battle of Condore. He came into direct contact, for the first time, with the Great Mogul himself, an event which resulted in the most important consequences during the third period of his career. Shah Alam, when *shahzada*, or heir-apparent, quarrelled with his father, Alam Gir II., the emperor, and united with the viceroys of Oudh and Allahabad for the conquest of Bengal. He advanced as far as Patna, which he besieged with 40,000 men. Jafar Ali, in terror, sent his son to its relief, and implored the aid of Clive. Major Caillaud defeated the prince's army and dispersed it. Finally, at this period, Clive repelled the aggression of the Dutch, and avenged the massacre of Amboyna, on that occasion when he wrote his famous letter, "Dear Forde, fight them immediately; I will send you the order of council to-morrow." Meanwhile he never ceased to improve the organization and drill of the sepoy army, after a European model, and enlisted into it many Mohammedans of fine physique from upper India. He refortified Calcutta. In 1760, after four years of incess-

sant labour his health gave way and he returned to England. "It appeared," wrote a contemporary on the spot, "as if the soul was departing from the Government of Bengal." He had been formally made governor of Bengal by the court of directors at a time when his nominal superiors in Madras sought to recall him to their help there. But he had discerned the importance of the province even during his first visit to its rich delta, mighty rivers and teeming population. It should be noticed, also, that he had the kingly gift of selecting the ablest subordinates, for even thus early he had discovered the ability of young Warren Hastings, destined to be his great successor, and, a year after Plassey, made him resident at the nawab's court.

In 1760, at 35 years of age, Clive returned to England with a fortune of at least £300,000 and the quit-rent of £27,000 a year, after caring for the comfort of his parents and sisters, and giving Maj. Lawrence, his old commanding officer, £500 a year. The money had been honourably and publicly acquired, with the approval of the company. The amount might have been four times what it was had Clive been either greedy after wealth or ungenerous to the colleagues and the troops whom he led to victory. He was well received at court, was made Baron Clive of Plassey, in the peerage of Ireland, bought estates, and got not only himself, but his friends returned to the House of Commons after the fashion of the time. He then set himself to reform the home system of the East India Company, and began a bitter warfare with Sullivan, chairman of the court of directors, whom in the end he defeated. In this he was aided by the news of reverses in Bengal. Vansittart, his successor, having no great influence over Jafar Ali Khan, had put Kasim Ali Khan, the son-in-law, in his place in consideration of certain payments to the English officials. After a brief tenure Kasim Ali had fled, had ordered Walter Reinhardt (known to the Mohammedans as Sumru), a Swiss mercenary of his, to butcher the garrison of 150 English at Patna, and had disappeared under the protection of his brother viceroy of Oudh. The whole company's service, civil and military, had become demoralized by gifts, and by the monopoly of the inland as well as export trade, to such an extent that the natives were pauperized, and the company was plundered of the revenues which Clive had acquired for them. The court of proprietors, accordingly, who elected the directors, forced them, in spite of Sullivan, to hurry out Lord Clive to Bengal with the double powers of governor and commander-in-chief.

What he had done for Madras, what he had accomplished for Bengal proper, and what he had effected in reforming the company itself, he was now to complete in less than two years, in this the third period of his career, by putting his country politically in the place of the emperor of Delhi, and preventing for ever the possibility of the corruption to which the British in India had been driven by an evil system. On May 3, 1765, he landed at Calcutta to learn that Jafar Ali Khan had died, leaving him personally £70,000, and had been succeeded by his son, though not before the Government had been further demoralized by taking £100,000 as a gift from the new nawab; while Kasim Ali had induced not only the viceroy of Oudh, but the emperor of Delhi himself, to invade Behar. After the first mutiny in the Bengal army, which was suppressed by blowing the sepoy ringleader from a gun, Major Munro, "the Napier of those times," scattered the united armies on the hard-fought field of Buxar. The emperor, Shah Alam, detached himself from the league, while the Oudh viceroy threw himself on the mercy of the British. Clive had now an opportunity of repeating in Hindustan, or Upper India, what he had accomplished in Bengal. He might have secured what are now called the United Provinces, and have rendered unnecessary the campaigns of Wellesley and Lake. But he had other work in the consolidation of rich Bengal itself, making it a base for the development of the mighty fabric of British India. Hence he returned to the Oudh viceroy all his territory save the provinces of Allahabad and Kora, which he made over to the weak emperor. But from that emperor he secured the most important document in the whole of British history in India up to that time, which appears in the records as "firmaund from the King Shah Aalum, granting the dewany of Bengal, Behar and Orissa to the company,

1765." The date was Aug. 12, the place, Benares, the throne an English dining-table covered with embroidered cloth and surmounted by a chair in Clive's tent. It is all pictured by a Mohammedan contemporary, who indignantly exclaims that so great a "transaction was done and finished in less time than would have been taken up in the sale of a jackass." By this deed the company became the real sovereign rulers of thirty millions of people, yielding a revenue of four millions sterling. On the same date Clive obtained not only an imperial charter for the company's possession in the Carnatic also, thus completing the work he began at Arcot, but a third firman for the highest of all the lieutenantancies of the empire, that of the Deccan itself. This fact is mentioned in a letter from the secret committee of the court of directors to the Madras government, dated April 27, 1768.

Having thus founded the empire of British India, Clive sought to reform the administration. The civil service was de-orientalized by raising the miserable salaries which had tempted its members to be corrupt, by forbidding the acceptance of gifts from natives, and by exacting covenants under which participation in the inland trade was stopped. Not less important were his military reforms. He put down a mutiny of the English officers, who chose to resent the veto against receiving presents and the reduction of batta at a time when two Mahratta armies were marching on Bengal. He reorganized the army, dividing the whole into three brigades, so as to make each a complete force, in itself equal to any single native army that could be brought against it. He had not enough British artillerymen, however, and would not make the mistake of his successors, who trained natives to work the guns, which were turned against the British with such effect in 1857.

Clive's final return to England, a poorer man than he went out, in spite of still more tremendous temptations, was the signal for an outburst of his personal enemies. Every civilian whose illicit gains he had cut off, every officer whose conspiracy he had foiled, every proprietor or director, like Sullivan, whose selfish schemes he had thwarted, now sought his opportunity. Clive had, with consistent generosity, at once made over the legacy of £70,000 from the grateful Jafar Ali, as the capital of what has since been known as "the Clive Fund," for the support of invalided European soldiers, as well as officers, and their widows, and the company had allowed 8% on the sum for an object which it was otherwise bound to meet. Gen. John Burgoyne, of Saratoga memory, did his best to induce the House of Commons, in which Lord Clive was now member for Shrewsbury, to impeach the man who gave his country an empire, and the people of that empire peace and justice. The result, after the brilliant and honourable defences of his career which will be found in Almon's *Debates* for 1773, was a compromise. On a division the House, by 155 to 95, carried the motion that Lord Clive "did obtain and possess himself" of £234,000 during his first administration of Bengal; but, refusing to express an opinion on the fact, it passed unanimously the second motion, at five in the morning, "that Robert, Lord Clive, did at the same time render great and meritorious services to his country." The one questionable transaction in all that brilliant and tempted life—the Omichund treaty—was not touched.

Only one who can personally understand what Clive's power and services had been will rightly realize the effect on him, though in the prime of life, of the discussions through which he had been dragged. In the greatest of his speeches, in reply to Lord North, he said—"My situation, sir, has not been an easy one for these 12 months past, and though my conscience could never accuse me, yet I felt for my friends who were involved in the same censure as myself . . . I have been examined by the select committee more like a sheep-stealer than a member of this House." Fully accepting that statement, and believing him to have been purer than his accusers in spite of temptations unknown to them, we see in Clive's end the result merely of physical suffering, of chronic disease which opium failed to abate, while the worry and chagrin caused by his enemies gave it full scope. This great man, who did more for his country than any soldier till Wellington, and more for the people and princes of India than any statesman in history, died by his own hand on Nov. 22, 1774, in his 50th year.

His son Edward (1754–1839) became Earl of Powis in 1804. See C. Caraccioli, *Life of Lord Clive* (1775); G. B. Malleson, *Lord Clive* ("Rulers of India" series) (1890); Sir C. Wilson, *Lord Clive* ("English Men of Action" series) (1890); F. M. Holmes, *Four Heroes of India* (1892); Sir A. J. Arbuthnot, *Lord Clive* ("Builders of Great Britain" series) (1899).

CLIVE, CAROLINE (1801–1873), English authoress, was born in London on June 24 1801, and died at Whitfield, Herts, on July 13 1873. She was the daughter of Mr. Meysey-Wigley, M.P. for Worcester, and married, in 1840, the Rev. Archer Clive. She is best known as the author of *Paul Ferroll* (1855), a sensational novel, and *Why Paul Ferroll killed his Wife* (1860).

CLIVE, CATHERINE (KITTY) (1711–1785), British actress, was born, probably in London, in 1711. Her father, William Raftor, an Irishman of good family but small means, had held a captain's commission in the French army under Louis XIV. About 1728 she began to play at Drury Lane, of which Colley Cibber was then manager. She married George Clive, a barrister and a relative of the 1st Lord Clive, but husband and wife soon separated by mutual consent. In 1731 she definitely established her reputation as a comic actress and singer in Charles Coffey's farce-opera adaptation, *The Devil to Pay*, and from this time she was always a popular favourite. She acted little outside Drury Lane, where in 1747 she became one of the original members of Garrick's company. She took part, however, in some of the oratorios of Handel, whose friend she was. In 1769, having been a member of Garrick's company for 22 years, she quitted the stage, and lived for 16 years in retirement at a villa at Twickenham, which had been given her some time previously by her friend Horace Walpole. Mrs. Clive had small claim to good looks, but as an actress of broad comedy she was unreservedly praised by Goldsmith, Johnson and Garrick. She had a quick temper, which on various occasions involved her in quarrels, and at times sorely tried the patience of Garrick, but her private life remained above suspicion, and she regularly supported her father and his family. She died at Twickenham on Dec. 6, 1785. Horace Walpole placed in his garden an urn to her memory, bearing an inscription, of which the last two lines run:—

The comic muse with her retired
And shed a tear when she expired.

See Percy Fitzgerald, *Life of Mrs. Catherine Clive* (1888); W. R. Chetwood, *General History of the Stage* (1749); Thomas Davies, *Memoirs of the Life of David Garrick* (1784).

CLOACA, the Latin term for a drain or sewer. The most famous is the Cloaca Maxima at Rome, built to drain the marsh where the Forum Romanum was situated. Constructed originally in about the 6th century B.C. as an open stone-lined channel, it was vaulted c. 4th or 5th century B.C., with a stone barrel vault.

CLOACA is also the name given to the joint opening of the urino-genital and alimentary systems characteristic of all the vertebrates except the mammals, among which it is only retained in the monotremata (*q.v.*).

CLOCKS. A clock consists of a train of wheels, actuated by a spring or weight or other means, and provided with an oscillating governing device which so regulates the speed as to render it uniform. Generally it has a mechanism by which it strikes the hours on a bell or gong (Fr. *cloche*; Ger. *Glocke*, a bell) whereas a timepiece simply shows the time.

History of Clocks.—The earliest clocks seem to have come into use in Europe during the 13th century, although there is evidence that they may have been invented some centuries sooner. The invention of the first clock is ascribed to Pope Silvester II. in A.D. 996. A clock was put up in a former clock-tower at Westminster in 1288, one in Canterbury cathedral in 1292, and another at St. Albans in 1326 which showed various astronomical phenomena. One placed in Dover Castle in 1348 was exhibited, going, in the Scientific Exhibition of 1876.

All these old clocks had the duty of keeping time. They were corrected occasionally by sundials or by crude astronomical observations. But sundials were of little use on dull days, and observatories were very few and maintained mainly for astrology. But

now the world is well supplied with observatories at which the correct time can be most accurately determined and communicated electrically to any point. The problem thus is to devise some simple mechanism that will have a steady rate for short intervals that can be accurately observed. It is the rate of going that is important. If we know the rate of error of a clock we can allow for it in an observatory or neglect it in common life. Our real timekeeper is the stars. The time is set all over the world by the consensus of a host of observatories.

FIG. 1.—VERGE ESCAPEMENT, SHOWING THE METHOD OF USING AN OSCILLATING MASS TO KEEP TIME

is mounted on pivots in proximity to a horizontal crown wheel *E*. The "pallets" *FG* are mounted on the horizontal axis so as alternately to engage the opposite teeth of the crown wheel. The crown wheel is caused to rotate by a cord and weight *H*. As it goes round, one of the pallets engages with a tooth, the swing of the verge is stopped, and the verge is given a swing in the opposite direction. The process is then repeated—the other pallet engaging a tooth on the other side of the crown wheel. Very heavy balls are needed to keep the period of oscillation approximately uniform. The friction on the axis, caused by the weight of the balls, is largely destructive of accuracy.

The Pendulum.—The verge escapement led to the idea of one ball at the lower end of a rod suspended by a flexible metal band. Such a ball was found to swing in periods which were very nearly uniform when the swings were not very unequal in amplitude. The time of swing varies with the square root of the length of the pendulum, and changes very little when the arc is slightly changed. When the length of the pendulum rod was 39.14 in., a difference of $\frac{1}{1000}$ in. of length was found to make the clock go slower by about a second a day; and when the arc of vibration of 3 in. was increased by $\frac{1}{10}$ in., the clock was again found to go slower by about a second a day. It is possible to express the time of going of a clock by a formula. Thus, let *L* be the length of the pendulum (39.14 in.), *G* twice the distance that a weight will fall to the earth in one second (32 ft.), π the ratio of the circumference of a circle to its diameter (3.1415), and *M* the arc of swing in inches.

Then the time of a single swing in seconds $= \pi \sqrt{\left[\frac{L}{G} \left(1 + \frac{M^2}{8L^2} \right) \right]}$ very nearly.

Compensation of Pendulums.—The equation given above, as well as practice, indicates that the time of swing of a pendulum is altered by temperature. The expansion of steel is about .0001 in. for each increase of 4° of temperature. The effect of temperature on the length and time of a particular pendulum can be computed. If a vessel of mercury about 7 in. in height is placed so as to rest on the bottom of an iron pendulum rod, it will expand so that the distance of its centre from the point of suspension is practically constant with varying temperatures. The use of the steel alloy (*invar*), which expands by heat only about one-tenth of the amount of ordinary steel, has greatly simplified the construction of accurate pendulums. There are several other factors which affect the real length of the pendulum, but, for reasons that have been explained, it is daily becoming less important to have extraordinary means of effecting compensation even in astronomical clocks. The true method of correction is by means

of stellar observation. The heat compensator is a needful adjunct to every clock that aspires to be more than a mere old "grandfather," but fine mechanical regulation is less necessary than in former years.

Escapements.—The term escapement is applied to any arrangement by which, as the wheels rotate, periodic impulses are given to the pendulum, while at the same time the motion of the wheels is arrested until the vibration of the pendulum has been completed. The escapement thus serves as a mechanism for both counting and impelling the pendulum and adapting the length of its swing to the impulse it has received. The best escapement is one which gives an impulse to the pendulum for a short period at the lowest point of its path, and then leaves it free until the time comes for the next impulse. It is also desirable that the impulses given to it shall be equal. The driving force of the escapement varies with the amount of energy absorbed by friction and with the thickness of the oil. It is therefore desirable to secure uniformity of impulse; e.g., by causing the train of wheels to lift a weight and let its drop act on the pendulum at regular intervals.

The two requirements above stated have given rise respectively to what are known as detached escapements and remontoires, which will be described presently. In the first place, however, it is desirable to describe the principal forms of escapement in ordinary use. The balance escapement was in use before the days of pendulums. It was to a balance escapement that Huygens applied the pendulum, by removing the weight from one arm and increasing the length of the other arm. Very shortly afterwards R. Hooke invented the anchor or recoil escapement. This is represented in fig. 2, where a tooth of the escape-wheel is just escaping from the right pallet, and another tooth at the same time falls upon the left-hand pallet at some distance from its point. As the pendulum moves on in the same direction, the tooth slides farther up the pallet thus producing a recoil, as in the crown-wheel or verge escapement. To get rid of this defect the dead escapement, or, as the French call it, *l'échappement à repos*, was invented by G. Graham. It is represented in fig. 3. The teeth of the scape-wheel have their points set the opposite way to those of the recoil escapement. The tooth *B* is here represented in the act of dropping on to the right-hand pallet as the tooth *A* escapes from the left pallet. But instead of the pallet having a continuous face as in the recoil escapement, it is divided into two, of which *BE* on the right pallet, and *FA* on the left, are called the impulse faces, and *BD*, *FG* the dead faces. The dead faces are portions of circles (not necessarily of the same circle), having the axis of the pallets *C* for their centre; and the consequence evidently is that, as the pendulum goes on, carrying the pallet still nearer to the wheel than the position in which a tooth falls on to the corner *A* or *B* of the impulse and the dead faces, the tooth still rests on the dead faces without any recoil, until the pendulum returns and lets the tooth slide down the impulse face, giving the impulse to the pendulum as it goes. In order to diminish the friction and the necessity for using oil as far as possible, the best clocks are made with jewels (sapphires are the best) let into the pallets.

The pallets are generally made to embrace about $\frac{1}{4}$ of the circumference of the wheel, and it is not at all desirable that they should embrace more; for the longer they are, the longer is the run of the teeth upon them, and the greater the friction. A not uncommon proportion is that out of a total arc of swing of 3° , 2° or about 1° on each side of the vertical, are occupied in receiving the impulse. In other words, the points *F* and *A* should sub-

FIG. 2.—ANCHOR OR RECOIL ESCAPEMENT, ONE OF THE EARLIEST ATTEMPTS TO USE A PENDULUM

FIG. 3.—DEAD ESCAPEMENT, A REFINEMENT OF THE ANCHOR ESCAPEMENT

tend an angle of 2° at the centre *C*. It is not to be forgotten that the scape-wheel tooth does not overtake the face of the pallet immediately, on account of the moment of inertia of the wheel.

One of the great obstacles to accurate timekeeping was that the train of wheels which drives the escapement is liable to variation of force. This is chiefly caused by cold, which thickens the oil, by wear of the parts, and by grit which gets into them. To obviate this an old suggestion was that the scape-wheel teeth should not be made to act directly on the pallets, but that each of them as it revolved should lift a weight which then fell on the pallets with a force which was nearly invariable. The scheme, however, was difficult to work out practically until Bloxam, a barrister, invented what is called the three-legged gravity escapement (fig. 4). As the pendulum swings out it lifts alternately the arms pivoted round centres *C*. This draws away the detents *E* and *F*, and allows the escape-wheel to rotate. But instead of the pendulum receiving its impulses from the pins on the escape-wheel, it receives them from the arms which are actuated by gravity, and all the escape-wheel does is to lift those arms and then release them. Lord Grimthorpe improved this escapement by adding a fly-vane to give a gentle movement to the escape-wheel and prevent banging. Big Ben at Westminster, London, was made with this gravity escapement and has gone excellently for over half a century.

FIG. 4.—THREE-LEGGED ESCAPEMENT ADOPTED TO UTILIZE GRAVITY TO GIVE UNIFORM IMPULSES TO A PENDULUM

One of the great difficulties in all these old escapements was that the driving force which impelled the pendulum on the one side and received its return impulses on the other was connected through all its motion with the pendulum rod. Now one of the necessities for true harmonic motion is to kick a mass into space, and let it swing freely till it came to rest and then swing back freely. Hence it was desirable as soon as the scape-wheel had delivered its impulse, to detach it from the pendulum, and then only let the pendulum come in contact with it again on its journey—in other words, to cause the action between the scape-wheel and pendulum to take place only at the centre of the swing. This gave rise to the chronometer spring escapement. All that need be done is to fix on to the pendulum a small ratchet or flipper arranged so as to push as it goes one way and miss as it returns (fig. 5). This flipper acts on a detent. When it pushes the detent one way, the detent releases an arm which gives the flying pendulum a push. But as the pendulum returns, the flipper passes the detent and allows the pendulum to swing free. Thus the pendulum receives an impulse on every alternate swing. A great many escapements have been designed on this plan for chronometers. One was invented by Robert Houdin, the conjurer, about 1830, and another by that great genius Sir George Airy (q.v.). A simple form (fig. 6) was designed by Sir Henry Cunyng-hame and has been keeping good time for the last 30 years. Its chief merit is that it does not depend for accuracy on expensive making. Let *A* be a block of metal fixed to the lower end of the pendulum rod; on this block let a small pall be fastened free to move round a centre *C* and resting against a stop *D*. Let *E* be a four-leaved scape-wheel, the teeth of which as they come round rest against the bent pall *GFL* at *G*. The pall is prevented from flying too far back by a pin *H*, and kept up to position by a very delicate spring *K*. As soon as the pendulum rod, moving from right to left, has arrived at the position shown in the figure, the pall *B* will engage the arm *FL*, force it forwards, and liberate the scape-wheel, a tooth of which, *M*, will thus close upon the heel of the block *A*,

6. Racks of kitchen clocks undergoing inspection after complete assembly

and urge it forward. As soon, however, as *M* has arrived at *G* the tooth *M* will slip off the block *A* and rest on the pall *G*, and the impulse will cease. The pendulum is now perfectly free or "detached" and can swing unimpeded as far as it chooses. On its return from left to right, the pall *B* slips over pall *L* without disturbing it, and the pendulum is still free to make an excursion towards the left. On its return journey the process is again repeated. Such an escapement operates once every two seconds,

FIG. 6.—DETACHED ESCAPEMENT, AN ENDEAVOUR TO APPLY THE CHRONOMETER MOVEMENT TO CLOCKS

and consideration will show that it is only the application of the detached chronometer escapement to a clock. It will be found very easy to make by an amateur. The escapement has a large arc to act upon, being on the lower part of the pendulum. A few attempts to combine the escapement with the detached escapement have been made. One is shown in fig. 7. It is only a modification of the detached escapement shown in fig. 6. It has worked very well for about 30 years, and seems to combine efficiency with simplicity. The lower part of the pendulum *A* carries a flipper *C* which, as the pendulum passes from right to left, engages the end of the detent *D*, which, moving towards the left, releases *E*, a tooth attached to the gravity arm *F*, thus allowing its end *G* to fall on the incline *H*, which is attached to the end of the pendulum. As soon as the pendulum has gone, *F* falls on an electric contact *K*, whereupon an electro-magnet hoists it up again so that it falls on end *E* of the detent, and disjoins the electric contact at *K*, whereupon the electro-armature *L* resumes its position. On the return from left to right, the flipper *C* slides over the end of the detent *D*. The arrangement of the armature *L* is similar to one arranged by F. Hope Jones for electric clock-winders. The object of making *H* double sided is that if the electricity ceases while the pendulum is swinging back from left to right, the part *H* shall not come into contact with *G* and be smashed, but simply slide over *G*. The escapement part of the clock is fixed on a frame attached to the suspension bracket of the pendulum by two steel rods of the same metal as the pendulum rod, so as to keep them in relative position in spite of temperature changes. The impulse given depends on the weight of the impulse arm. The work done in unlocking the detent is invariable, as it is independent of the electric drive. The duration of the impulse is very short, only about one-tenth of the arc of the swing. It is given exactly at the centre of the swing, and when not under impulse the pendulum is detached.

Clock Wheels.—To keep the force which acts on the pendulum uniform is the object of the best escapement. Inasmuch as the impulse on the pendulum, derived from the work done by a falling weight or an unwinding spring, is transmitted through a train of wheels, it is desirable that transmission should be as free from friction and as regular as possible. This involves care in the shaping of the teeth. The object to be aimed at is that as the wheel turns around, the ratio of the power of the driver to that of the driven wheel ("runner" or "follower") should never vary. The teeth of the wheels are given an epicycloidal form.

Going Barrels.—A clock must have some contrivance to keep it going while it is being wound up. In the old-fashioned house clocks this was done by what is called the endless chain of Huygens. This kind of going barrel, however, is evidently not suited to an astronomical clock, and Harrison's going barrel is now universally adopted. Fig. 8 shows its construction. The click of

the barrel-ratchet *R* is set upon another larger ratchet-wheel with its teeth pointing the opposite way, and its click *T* is set in the clock frame. That ratchet is connected with the great wheel by a spring *s*'s pressing against the two pins *s* in the ratchet and *s* in the wheel. When the weight is wound up (which is equivalent to taking it off), the click *T* prevents that ratchet from turning back

FIG. 8.—HARRISON'S GOING BARREL, WHICH KEEPS THE MODERN CLOCK GOING WHILE IT IS BEING WOUND UP

or to the right; and as the spring *s*'s is kept by the weight in a state of tension equivalent to the weight itself, it will drive the wheel to the left for a short distance, when its end *s* is held fast, with the same force as if that end was pulled forward by the weight; and as the great wheel has to move very little during the short time the clock is winding, the spring will keep the clock going long enough.

Remontoire.—To abolish errors arising from the changes in the force driving the escapement, what is known as the "remontoire" system was adopted. It first came into use for watches. The idea of remontoire is to disconnect the escapement from the clock-train, and to give the escapement a driving power of its own, acting as directly as possible on the pallets without the intervention of a clock-train. The escapement is thus made into a separate clock, which of course needs repeated winding, and this winding is effected by the clock-train. From this it results that variations in the force transmitted by the clock-train merely affect the speed at which the "rewinding" of the escapement is effected, but do not affect the force exerted by the driving power of the escapement.

There are several modes of carrying out this plan. The first of them is simply to provide the scape-wheel with a weight or spring of its own, which spring is wound up by the clock-train as often as it runs down. Contrivances of this kind are called train remontoires. In arranging such a remontoire it is obvious that the clock-train must be provided with a stop to prevent it from overwinding the scape-wheel weight or spring, and further, that there must be on the scape-wheel a stud or other contrivance to release the clock-train as soon as the scape-wheel weight or spring has run down and needs rewinding. The first maker of a large clock with a train remontoire was probably Thomas Reid, of Edinburgh, who described his apparatus in his book on *Horology* (1819). A clock at the Royal Exchange, London, was made in 1844 on this principle.

In these gravity remontoires, however, only the friction of the heavy parts of the train and the dial-work is got rid of, and the scape-wheel is still subject to the friction of the remontoire wheels, which though much less than the other, is still considerable. Accordingly, attempts have frequently been made to drive the scape-wheel by a spiral spring, like the mainspring of a watch. Sir G. Airy invented one, of which one specimen is still going well.

General View of a Common Clock.—The general construction of the going part of all clocks, large or turret clocks, is substantially the same, and fig. 9 is a section of any ordinary house clock. *B* is the barrel with the cord coiled round it. The barrel is fixed to its arbor *K*, which is prolonged into the winding square coming up to the face or dial of the clock. The great wheel *G* rides on the arbor, and is connected with the barrel by the ratchet *R*, the action of which is shown more fully in fig. 10. The great wheel drives the pinion *c*, which is called the centre pinion, on the arbor of the centre wheel *C*, which goes through to the dial, and carries the long, or minute hand. The centre wheel drives the second wheel *D* by its pinion *d*, and that again drives the scape-wheel *E* by its pinion *e*. If the pinions *d* and *e* have each eight teeth or leaves, *C* will have 64 teeth and *D* 60, in a clock of which the scape-wheel turns in a minute, so that the second hand may be

FIG. 7.—ELECTRIC GRAVITY DETACHED ESCAPEMENT, COMBINING GRAVITY WITH THE DETACHED CHRONOMETER MOVEMENT AND UTILIZING ELECTRICITY TO DRIVE THE CLOCK

set on its arbor prolonged to the dial. *A* represents the pallets of the escapements and their arbor *a* goes through a large hole in the back plate near *F*, and its back pivot turns in a cock *OFQ* screwed on to the back plate. From the pallet arbor at *F* descends the crutch *Ff*, ending in the fork *f*, which embraces the pendulum *P*, so that as the pendulum vibrates, the crutch and the pallets necessarily vibrate with it. The pendulum is hung by a thin spring *S* from the cock *Q*, so that the bending point of the spring may be just opposite the end of the pallet arbor, and the edge of the spring as close to the end of that arbor as possible.

The minute hand fits on to a squared end of a brass socket, which is fixed to the wheel *M*, and fits close, but not tight, on the prolonged arbor of the centre wheel. Behind this wheel is a bent spring which is set on the same arbor with a square hole in the middle, so that it must turn with the arbor; the wheel is pressed up against this spring, and kept there by a cap and a small pin through the end of the arbor. The consequence is that there is friction enough between the spring and the wheel to carry the hand round, but not enough to resist a moderate push with the finger for the purpose of altering the time indicated. This wheel *M* drives another wheel *N*, of the same number of teeth, which has a pinion attached to it; and that pinion drives the 12 hour wheel *H*, which is also attached to a large socket or pipe carrying the hour hand, and riding on the former socket. The weight *W*, which drives the train and gives the impulse to the pendulum through the escapement, is generally hung by a catgut line passing through a pulley attached to the weight, the other end of the cord being tied to some convenient place in the clock frame or seat-board, to which it is fixed by screws through the lower pillars.

Striking Mechanism.—Fig. 10 is a front view with the face taken off, showing the repeating or rack-striking movement. *M* is the hour-wheel, on the pipe of which the minute-hand is set; *N* the reversed hour-wheel, and *n* its pinion, driving the 12-hour wheel *H*, on whose socket is fixed what is called the snail *Y*, which belongs to the striking work exclusively. The hammer is raised by the eight pins in the rim of the second wheel in the striking train. The hammer does not quite touch the bell, as it would jar in striking and muffle the full sound. The form of the hammer-shank at the arbor where the spring *S* acts upon it is such that the spring both drives the hammer against the bell when the tail *T* is raised, and also checks it just before it reaches the bell, the blow on the bell thus being given by the bending of the hammer shank. Sometimes two springs are used, one for impelling the hammer and the other for checking it. But nothing will check the chattering of a heavy hammer, except making it lean forward so as to act, partially at least, by its weight. The pinion of the striking-wheel generally has eight leaves, the same number as the pins; and as a clock strikes 78 blows in 12 hours, the great wheel will turn in that time if it has 78 teeth instead of 96, which the great wheel of the going part has for a centre pinion of eight. The striking-wheel drives the wheel above it once round for each blow; that wheel drives a fourth (in which there is a single pin *P*), six or any other integral number of turns for one turn of its own. A fan-fly moderates the velocity of the train by the resistance offered by the air.

Church and Turret Clocks.—A clock is a machine in which the only work to be done is the overcoming of its own friction and the resistance of the air. It is evident that when the friction and resistance are much increased it may become necessary to neutral-

ize their effects. In a turret clock the friction is enormously increased by the great weight of all the parts and the resistance of the wind, and sometimes snow, to the motion of the hands. Besides that, there is the exposure of the clock to dirt and dust, and of the oil to a temperature which nearly or quite freezes it. This last circumstance alone will generally make the arc of the pendulum at least half a degree more in summer than in winter.

Inasmuch as the time is materially affected by the force which arrives at the pendulum, as well as the friction on the pallets when it does arrive there, it is evidently impossible for any turret clock of the ordinary construction, especially with large dials, to keep any constant rate through the various changes to which it is exposed. Hence special precautions, such as the use of remontoires and gravity escapements, have to be observed in the design of large clocks in order to ensure that the arc of the pendulum is not affected by external circumstances. But such have been the improvements effected in electric clocks, that it appears far preferable to keep an accurate timepiece in some sheltered position and use it with a source of electricity to drive the hands of the large dial.

There are many turret clocks in various parts of Europe, and a limited number in England. The largest of them is the Strasbourg clock of 1547. It aims at showing the movements of the earth and stars as well as the time, also the seasons, epochs of the year,

FIG. 9.—SECTION OF THE SIDE VIEW OF A COMMON HOUSE CLOCK WITHOUT STRIKING MOVEMENT

FIG. 10.—DIAGRAM OF A FRONT VIEW OF COMMON ENGLISH HOUSE CLOCK WITH STRIKING MOVEMENT

moral emblems and the life of man; it was restored in 1842. Some of these clocks contain large figures which strike the hours.

The Portable Clock.—Simultaneously with the development of the case clock, the watch was evolved. The need for it arose from the impossibility of moving the pendulum clock from place to place. The first use of a mainspring was probably in the 16th century. It was used for watches, then called Nuremberg eggs. The escapement was usually of the verge form with a crown wheel. A table clock, early 17th century, is shown in the plate. The escapement is furnished with a balance wheel governed by a hair spring.

The most usual pattern of portable clock in England (*see* Plate) has a pendulum of about 10 in. in length beating half seconds, a striking mechanism, shows the days of the month and dates from about the middle of the 18th century. After this period, the tendency was for portable clocks to become smaller. In the Plate are shown two characteristic table clocks, one by the famous maker, Valliomy, and the other of a flat shape mounted in a gilt stand, suitable for travelling.

A great number of ornamental cases for portable clocks were made in the 18th and 19th centuries. A rather handsome one is shown in the Plate. It is of enamelled copper, mounted in gilt frames. It has on the reverse side five dials showing the positions of the moon and planets. It has also a repeater, which, by pulling a string, causes the hour to sound whenever wanted. This is an old plan much used before the invention of lucifer matches.

Two hands for clocks came in about the commencement of the 18th century.

Old and Modern Clocks Compared.—Of old makers the most distinguished was Thomas Tompion, at whose works a vast quantity of beautiful clocks and watches were made during the latter part of the 17th century. He is called the father of English watchmaking. The name next to Tompion is that of his pupil, George Graham, who flourished during the early part of the 17th century, and who invented the mercurial pendulum and the dead-beat escapement. Quare is another maker whose clocks are valuable. A collection of stand clocks is to be seen at the South Kensington museum.

Robert Hooke (*q.v.*) was the first who drew attention to the fact that springs when stretched resist with a force proportional to their extension, and thus helped to lay the foundation of the laws of harmonic motion as applied to clockwork. He also invented a wheel-cutting device and the anchor escapement.

Huygens was one of the originators of the application of the pendulum to the clock and the inventor of the going barrel. Harrison invented the "grid-iron" pendulum, and also enormously improved the chronometer, by means of which he proved that the Board of Admiralty was a whole day's sail out of the proper reckoning of the island of Madeira. This chronometer in one experiment kept time to within 65 minutes in about five months, which was a wonderful performance in those days, for it was then thought quite a feat to determine the position of a ship at sea by means of a chronometer to 40 miles.

Modern household clocks are now made with short 10 in. pendulums, and frequently are wound up by electricity at short intervals. Companies provide master-clock control for hotels and public buildings. These clocks do not aim at the accuracy of astronomical clocks, but they are admirably adapted for the uses of ordinary life.

Electrical Clocks.—Electrical timepieces only differ from timepieces driven by weights or springs in that some arrangement is made to use electricity to wind up those weights or springs mechanically, either at every beat of the pendulum or at intervals. With dry batteries small clocks can be made to run for a long time without attention. For bigger clocks it is possible to use the electric lighting supply. This is not difficult where the current is continuous, but where it is alternating, a transformer or a special synchronous design known as the telechron (*q.v.*) is used. An ingenious form is the well-known Hipp's clock at the observatory of Neuchâtel in which, as the pendulum passes its lowest point, a vertical flipper is made to close an electrical circuit. Its average variation from its daily rate is about one-thirtieth of a second.

The bibliography of horology is very extensive. Among modern works Lord Grimthorpe's *Rudimentary Treatise on Clocks, Watches and Bells* (8th ed., 1903) is perhaps the most convenient. Many references to older literature will be found in Thomas Reid's *Treatise on Clocks and Watchmaking* (1849). (H. H. C.)

THE CLOCK IN DECORATION

In art the clock occupies a position of considerable distinction, and antique examples are prized and collected as much for the decorative qualities of their cases as for the excellence of their timekeeping. French and English cabinetmakers have especially excelled, although in entirely different ways, in the making of clock

cases. The one aimed at comely utility, often made actually beautiful by fit proportion and the employment of finely grained woods; the other sought a bold and dazzling splendour in which ornament over-lay material. It was not in either country until the latter part of the 17th century that the cabinet-maker's opportunity came. The bracket or chamber clock gave comparatively little scope to the worker in wood—in its earlier period, indeed, it was almost invariably encased in brass or other metal; and it was not until the introduction of the long pendulum swinging in a small space that it became customary to encase clocks in decorative woodwork. What is, perhaps, the earliest surviving English specimen of "grandfather" clock is inscribed with the date 1681. Originally it was a development of the dome-shaped bracket clock, and in the older examples the characteristic dome or canopy is preserved. The first timekeepers of this type had oaken cases but when walnut began to come into favour that beautifully marked wood was almost invariably used for the choicest and most costly specimens. Thus in 1698 the dean and chapter of St. Paul's cathedral paid the then very substantial price of £14 for an inlaid walnut long-cased eight-day clock to stand in one of the vestries. Throughout the 18th century they were made in myriads all over England, and since they were a prized possession it is not surprising that innumerable examples have survived. Vary as they may in height and girth, in wood and dial, they are all essentially alike. In their earlier years their faces were usually of brass engraved with cherubs' heads or conventional designs, but eventually the less rich white face grew common. There are two varieties—the eight-day and the 30-hour. The favourite walnut case of the late 17th and early 18th centuries gave place in the course of a generation to mahogany, which retained its primacy until the introduction of cheaper clocks brought about the supersession of the long-cased variety. Many of these cases were made in lacquer when that material was in vogue; satinwood and other costly foreign timbers were also used for bandings and inlay. The most elegant of the "grandfather" cases are, however, the narrow-waisted forms of the William and Mary period in walnut inlay, the head framed in twisted pilasters. During the later period of their popularity the heads of long clocks were often filled in with painted discs representing the moon, by which its course could be followed. Such conceits as ships moving on waves or time with wings were also in favour. The northern parts of France likewise produced tall clocks, usually in oaken cases; those with Louis XV. shaped panels are often very decorative. French love of applied ornament was, however, generally inimical to the rather uncompromising squareness of the English case, and the great Louis XV. and Louis XVI. cabinet-makers made some magnificent and monumental clocks, many of which were "long" only as regards the case, the pendulum being comparatively short, while sometimes the case acted merely as a pedestal for a bracket-clock fixed on the top. These pieces were usually mounted very elaborately in gilt bronze, cast and chased, and French bracket and chamber clocks were usually of gilded metal or marble, or a combination of the two; this essentially late 18th-century type still persists. English bracket clocks contemporary with them were most frequently of simple square or arched form in mahogany. The "grandfather" case was also made in the Low Countries, of generous height, very swelling and bulbous.

See Mathieu Planchon, *L'Horloge, son histoire retrospective, pittoresque et artistique* (1899); F. J. Britten, *Old Clocks and Watches and their Makers* (2nd ed., 1904). (J. P.-B.)

THE CLOCK TRADE IN GREAT BRITAIN

The consumption of clocks in Great Britain is enormous and it is very largely met by importation from abroad. In the 17th and 18th centuries clock-making was mainly centred in England and France, but the modern output of low-priced clocks has become mainly the produce of German and American factories. At one time before the World War, a German kitchen clock was freely sold retail in England for a few shillings. The manufacture in England of the better sort of clock is still carried on at London, Coventry, Croydon, Derby and other places on a fairly large scale; in several instances munition factories have been

turned to clock-making.

There is also an English industry engaged in placing imported movements in British-made cases. The extent of this may be gathered from the fact that under the heading "parts of clocks" the imports into the United Kingdom in 1925 were valued at £1,239,000 and in 1926 at £463,000. A number of British manufacturers are producing clocks on mass-production lines with success, and it is claimed that the protection they have obtained of a 33½% import duty is of great assistance to the trade. The imports of clocks into the United Kingdom fell from a value of £1,099,000 in 1925 to £376,000 in 1926. The exportation of British clocks from the United Kingdom is negligible; it amounted in 1926 to a value of £12,690. (X.)

CLOCK INDUSTRY IN AMERICA

The clock industry showed an entirely different development in America from that in Europe. In Europe, clocks were made by jewellers, locksmiths, blacksmiths, astronomers and priests. The new world recruited its first clock-makers from the ranks of the carpenters, and consequently the oldest American clocks were constructed of wood. In New England, which is still the greatest manufacturer of watches and clocks in the world, the new industry was born, and Eli Terry of Connecticut was one of the first and best-known clock-makers. It is well-known that he and his helpers made a few dozen clocks by hand, and Eli mounted his horse, with clocks hanging from the saddle, and sold them to the farmers in the surrounding countries. Terry was the first clock-maker to use machinery, when his orders began to increase, and thus became a clock manufacturer in the true sense of the word. Another old time clock mechanic, who developed into a clock manufacturer, was one of Eli Terry's helpers, Seth Thomas. His honest and clever workmanship built up a business that is still one of the largest and best-known in America. It is carried on in a large clock factory whose product still carries his name. It was Chauncey Jerome, another New Englander, who saw the great advantages of using brass instead of wood in clock movements. Through this change in material, clock movements became less cumbersome and easier to transport, and most important of all, cheaper. Eli Terry's hand-made clocks sold for about \$40 apiece. Jerome's clocks could be bought for from \$5 to \$6 each. In America, in contrast to European conditions, the individual clock-makers were absorbed by larger corporations, as the following description shows. Chauncey Jerome leased together with E. D. Bryant a building from the American Brass and Copper Company, located in Ansonia in the Naugatuck valley, the centre of the present clock manufacturing district, for the manufacture of clock cases and clock movements. Subsequently, both makes of cases and movements passed into the hands of the Ansonia Brass and Copper Company. The business of the Ansonia Brass and Copper Company assumed such magnitude that in 1877 a re-organization became desirable, and a new corporation was formed under the name of the Ansonia Clock Company.

The American manufacturers concentrated from the start in the elimination of costly handwork. The old way of making a clock was to have a master-mechanic build a model clock, which after it had passed inspection and test runs would be taken apart, the parts distributed to different workmen, who had to copy these parts as closely as possible; these parts then were returned to the clock-maker, who assembled and adjusted them again. Although all of these clocks were expected to be alike, no part of one of them could be interchanged with the same part of another clock. It was, therefore, the aim of the early Yankee clock-makers to produce a clock with interchangeable parts, which was accurate in telling time, and cheap enough to bring it within the reach of everyone. Even though all theoretical work had been finished in the European clock-making countries, there remained still the work of mass production. Fortunately the period coincided with the period of great American inventiveness. In this period, the old method of producing all work by hand was rapidly superseded by new methods, where new machinery was invented and used in all branches of manufacture. When the means for more rapid producing of parts had been obtained other factors had to be con-

sidered, not only the design of the clock as timekeeper had to be correct, parts to be absolutely interchangeable, and the ease of assembly had to be taken into consideration, but also much thought had to be given to making the work of the clock-repairer easy, in order that the price of any eventual repairing would not be prohibitive.

In 1850 a firm that could boast seven timepieces a day, was doing well. In 1928 clock companies could produce from 10,000 to 30,000 timepieces each, per day. As a result prices tumbled so that a watch or an alarm clock which will give good service can be bought for as low as \$1.00. The number of pieces in a watch or clock have not materially changed since clocks were first made. It is only through the replacement of handwork by machinery, that modern production and low prices become possible. Almost all new inventions in the clock field are not so much concerned with different designs or reduction of parts as with easier and cheaper manufacturing. With the advent of the radio, and the broadcasting of the exact time, the public has become more exacting as regards the time-keeping qualities of clocks and watches. The owner checks his timepiece with the observatory time signals, and is dissatisfied if there is any variation. (W. H. BA.)

CLODIA, VIA, an ancient high-road of Italy. Its course, for the first 11 m., was the same as that of the *Via Cassia*; it then diverged to the north-north-west and ran on the west side of the *Lacus Sabatinus*, past Forum Clodii and Blera (mod. Bieda) to Tuscania, after which its course is uncertain. According to Millee (*Itineraria Romana*) it went on by Maternum (Valentano) Acquapendente, Radicofani, Buonconvento Siena, and Luca past another Forum Clodii to Luna: but this is doubtful. In parts it follows older Etruscan roads, and may date from the end of the 4th century B.C. See also CASSIA, VIA.

See D. Anziani in *Mélanges de l'École Française de Rome*, 1913, 169 sqq.

CLODIUS, PUBLIUS (c. 93–52 B.C.), surnamed PULCHER, Roman politician. He took part in the third Mithridatic War under his brother-in-law Lucius Licinius Lucullus, but considering himself treated with insufficient respect he stirred up a revolt; another brother-in-law, Q. Marcius Rex, governor of Cilicia, gave him the command of his fleet, but he was captured by pirates. On his release he repaired to Syria, where he nearly lost his life during a mutiny instigated by himself. Returning to Rome in 65, he prosecuted Catiline for extortion, but was bribed by him to procure acquittal. There seems no reason to believe that Clodius was implicated in the Catilinarian conspiracy; according to Plutarch he supported Cicero. But Cicero attacked him when he was on trial for profaning the mysteries of the Bona Dea (61), and this made Clodius his enemy for life and he became the tool of Caesar. On his return from Sicily (where he had been quaestor in 61) he was adopted by a plebeian and elected tribune of the people (59). His first act was to bring forward certain laws calculated to secure him the popular favour. Corn was to be distributed gratuitously once a month; the magistrates' right of preventing the assembly of the comitia was abolished; the old guilds of workmen were re-established; the censors were forbidden to exclude any citizen from the senate or inflict any punishment upon him unless he had been publicly accused and condemned. He then contrived the exile of Cicero and the despatch of the younger Cato on a mission to Cyprus. Cicero's property was confiscated by order of Clodius. After the departure of Caesar for Gaul, Clodius became practically master of Rome by means of his armed gangs. But he fell out with Pompey and was not re-elected for 57, while one of the Tribunes, Milo, countered his force with force, so despite his opposition, in Aug. 57 Cicero was recalled. Riots between Clodius and Milo continued; in 56, when *curule aedile*, Clodius impeached Milo for public violence (*de vi*), but the matter was dropped. In 53, when Milo was a candidate for the consulship, and Clodius for the praetorship, the rivals collected armed bands and fights took place in the streets of Rome, and on Jan. 20, 52, Clodius was slain near Bovillae.

His sister, CLODIA, wife of Q. Caecilius Metellus Celer, was notorious for her numerous love affairs. It is now generally admitted that she was the Lesbia of Catullus (Teuffel-Schwabe,

Hist. of Roman Lit., Eng. tr., 214, 3). For her intrigue with M. Caelius Rufus, whom she afterwards accused of attempting to poison her, see Cicero, *Pro Caelio*.

CLOGHER, a small village, Co. Tyrone, Ireland. Pop. (1921) 197. It gives its name to dioceses of the Church of Ireland and the Roman Catholic Church, though the seat of the bishop of the latter is at Monaghan. The dedication of the Protestant cathedral to St. Macartin is of interest, for although the building is modern, St. Macartin is associated with St. Patrick, who is said to have founded a bishopric here. The name is derived from *cloth*, a pillar stone—an object of worship in the locality, preserved in the cathedral until the 15th century.

CLOISTER originally signified an entire monastery, but is now restricted to mean the four-sided enclosure, surrounded with covered ambulatories, usually attached to conventual and cathedral churches, and sometimes to colleges, or, by a still further limitation, to the ambulatories themselves. In its older sense it is frequently used in earlier English literature and is still so employed in poetry. The Latin *claustrum*, as its derivation implies, primarily denoted the enclosing wall of a religious house, and then came to be used for the whole enclosed building. To this sense the German *Kloster* is still limited, the covered walks, or cloister in the modern sense, being called *Klostergang*, or *Kreuzgang*. In French the word *cloître* retains the double sense. In the special sense now most common, the word "cloister" denotes the quadrilateral area in a monastery or college, round which the principal buildings are ranged, and which is usually provided with a covered way or ambulatory running all round, and affording a means of communication between the various centres of the ecclesiastical life. According to the Benedictine arrangement, which from its suitability to the requirements of monastic life was generally adopted in the West, one side of the cloister was formed by the church, the refectory occupying the side opposite to it, so that the worshippers might have the least annoyance from the noise or smell of the repasts. On the eastern side the chapter-house was placed, with other apartments adjacent to it, belonging to the common life of the brethren, and, as a rule, the dormitory occupied the whole upper story. On the opposite or western side were generally the cellarer's lodgings, with the cellars and store-houses, in which the necessary provisions were housed. In Cistercian monasteries the western side was usually occupied by the *domus conversorum*, or lodgings of the lay-brethren, with their day-rooms and workshops below, and dormitory above. The cloister, with its surrounding buildings, generally stood on the south side of the church, to secure as much sunshine as possible. A very early example of this disposition is seen in the plan of the monastery of St. Gall. Local requirements caused the cloister, in some instances, to be placed to the north of the church. This is the case at Canterbury, Gloucester, Chester and Lincoln cathedrals.

Although the covered ambulatories are essential to the completeness of a monastic cloister, a chief object of which was to enable the inmates to pass under cover from one part of the monastery to another, they were sometimes wanting. The cloister at St. Albans seems to have been deficient in ambulatories till the abbacy of Robert of Gorham, 1151–66, when the eastern walk was erected. This, as was often the case with the earliest ambulatories, was of wood, covered with a sloping roof or "penthouse." We learn from Osborn's account of the conflagration of the monastery of Christ Church, Canterbury, 1067, that a cloister with covered ways existed at that time, connecting the church, the dormitory and the refectory. An early drawing of the monastery of Canterbury shows it formed by Norman arches supported on shafts, and covered by a shed roof. A fragment of such an arcaded cloister is still found on the eastern side of the infirmary cloister. This ear-

lier form of cloister has been generally superseded in England by a range of windows, usually unglazed, but sometimes, as at Gloucester, provided with glass, lighting a vaulted ambulatory, of which the cloisters of Westminster Abbey, Salisbury and Norwich are typical examples. The older design was preserved in the south, where "the cloister is never a window, but a range of small elegant pillars, sometimes single, sometimes coupled, and supporting arches of a light and elegant design" (Fergusson, *Hist. of Arch.*, i., p. 610). Examples of this type are the exquisite cloisters of St. John Lateran, and St. Paul's without the walls, at Rome, where the coupled shafts and arches are richly ornamented with ribbons of mosaic, and those of the convent of St. Scholastica at Subiaco, all of the 13th century, and the beautiful cloisters of Le Puy-en-Velay, and Arles, in southern France (both 11th century) and that at Laach, where the quadrangle occupies the place of the "atrium" of the early basilicas at the west end, as at S. Clemente at Rome, and S. Ambrogio at Milan. Spain also presents some magnificent cloisters of both types, of which that of the royal convent of Huelgas, near Burgos, of the arcaded form, is, according to Fergusson, "unrivalled for beauty both of detail and design." Also notable are those of Monreale and Cefalu in Sicily (12th century), where the arrangement is the same, of slender columns in pairs with capitals of elaborate foliage supporting pointed arches of great elegance of form.

The Campo Santo at Pisa is in reality a large and magnificent cloister. It consists of four ambulatories as wide and lofty as the nave of a church, erected in 1278 by Giovanni Pisano, round a cemetery composed of soil brought from Palestine by Archbishop Lanfranchi in the middle of the 12th century. The window-openings are semicircular, filled with elaborate tracery in the latter half of the 15th century. The inner walls are covered with frescoes, invaluable in the history of art, by Orcagna, Simone Memmi, Buffalmacco, Benozzo Gozzoli, and other early painters of the Florentine school. The ambulatories now serve as a museum of sculpture. The great monastic establishments of Italy contain numerous important cloisters; there are frequently two or three in a single monastery—one large cloister for the general use of the monks, and smaller cloisters in connection with the residence of the prior or abbot, the service portions and various other minor buildings. The cloisters at the Certosa at Pavia (15th century) are notable for their size and quaint, early Renaissance ornament. In the Certosa at Rome, now part of the Museo delle Terme, the cloister is a large arcade of pure and simple Renaissance type. Another interesting Renaissance example is that which Bramante designed for the church of S. Maria della Pace at Rome 1504. Later Renaissance cloisters tended more and more to become duplicates of palace courtyards.

The cloister of a religious house was the scene of a large part of the life of its inmates. It was the place of education for the younger members, and of study for the elders. A canon of the Roman council of 826 enjoins the erection of a cloister as an essential portion of an ecclesiastical establishment for the better discipline and instruction of the clerks. Peter of Blois describes schools for the novices as being in the west walk, moral lectures being delivered in that next the church. At Canterbury the monks' school was in the western ambulatory, and it was there that the novices were taught at Durham (Willis, *Monastic Buildings of Canterbury*, p. 44; *Rites of Durham*, p. 71). The other alleys, especially that next the church, were devoted to the studies of the elder monks. The constitutions of Hildemar and Dunstan enact that between the church service the brethren should sit in the cloister and read theology. For this purpose small studies, known as "carrols," i.e., a ring or enclosed space, were often found in the recesses of the windows. Of this arrangement there are examples at Gloucester and Chester. The use of these studies is thus described in the *Rites of Durham*: "In every wyndowe" in the north alley "were iii. pewes or carrells, where every one of the olde monkes had his carrell severally by himselfe, that when they had dynded they dyd resorte to that place of cloister, and there studyed upon their books, every one in his carrell, all the afternonne unto evensong tyme. This was there exercise every daie." On the opposite wall were cupboards full of books for the

use of the students. The cloister arrangements at Canterbury were similar. New studies were made by Prior De Estria in 1317, and Prior Selling (1472-94) glazed the south alley, and constructed "the new framed contrivances, of late styled carrols" (Willis, *Mon. Buildings*, p. 45).

The cloisters were used also for recreation. The constitutions of Archbishop Lanfranc, sec. 3, permitted the brethren to converse together there at certain hours. To maintain discipline a special officer was appointed under the title of *prior claustrii*. The cloister was furnished with a stone bench running along the side. It was also provided with a lavatory, usually adjacent to the refectory, but sometimes standing in the central area termed the cloister-garth, as at Durham. The cloister-garth was used as a place of sepulture, as well as the surrounding alleys. The cloister was in some few instances of two stories, as at Old St. Paul's and St. Stephen's chapel, Westminster, and occasionally, as at Wells, Chichester and Hereford, had only three alleys, there being no ambulatory under the church wall.

The larger monastic establishments had more than one cloister; there was usually a second connected with the infirmary, of which there are examples at Westminster Abbey and at Canterbury; and sometimes one giving access to the kitchen and other domestic offices. The cloister was not an appendage of monastic houses exclusively. It was also attached to colleges of secular canons, as at the cathedrals of Lincoln, Salisbury, Wells, Hereford and Chichester, and formerly at St. Paul's and Exeter. A cloister forms an essential part of the colleges of Eton and Winchester, and of New college and Magdalen at Oxford. These were used for religious processions and lectures, and for places of exercise for the inmates generally in wet weather, as well as in some instances for sepulture.

CLONAKILTY, urban district, Co. Cork, Ireland, at the head of Clonakilty bay, 33 m. S.W. of Cork by rail. Pop. (1926) 2,771. There are megaliths in the neighbourhood. Richard Boyle, first earl of Cork, granted it a charter in 1613 and it was prosperous until 1641, when it was almost destroyed in a fight between the English and Irish. There are castles at Galley Head, Dunnycove and Dunowen. The linen industry was important in the 18th century. The present trade is in brewing, agricultural produce and fishing. The harbour is obstructed, but there is a pier for large vessels at Ring 1 m. below the town. The fisheries are of importance.

CLONES, an urban district of Co. Monaghan, Ireland, 64½ m. S.W. by W. from Belfast by the Great Northern of Ireland railway. It is at the focus of ways from Dublin, Belfast, Londonderry, Enniskillen and Cavan. Pop. (1921) 2,358. There is a rath (encampment) in the vicinity. Clones was the seat of an abbey founded in the 6th century by St. Tighernach (Tierney). Remains of the abbey include a nave and tower of the 12th century. There is a round tower 75 ft. high. The market-place, called the Diamond, has an ancient cross and occupies the summit of the hillock on which the town stands. Lace making is now extinct, but the town has agricultural trade.

CLONMACNOISE, a famous early Christian centre on the river Shannon, Offaly Co., Ireland, 9 m. south of Athlone. An abbey founded 541 by St. Kieran became famous and several books of annals were compiled here; Alcuin came to be taught by Colcu at Clonmacnoise. The Book of the Dun Cow (written about 1100) is a copy of an older collection of romances written on the skin of a cow of St. Kieran. The ecclesiastical foundation was called the Seven Churches of Clonmacnoise and their remains still survive. The fine west doorway of the Great Church is early; the other churches are those of Fineen, Conor, St. Kieran, Kelly, Melaghlín and Dowling. There are two round towers, O'Rourke's and McCarthy's, which is attached to Fineen's church and has a doorway at ground-level, an unusual feature. There are three crosses, the Great Cross facing the door of the Great Church. Many inscribed stones of the ninth century and later are preserved in the churches. Clonmacnoise became a bishopric and there are remains of a castle and bishop's palace (14th century), it was wasted by the English in 1552, and in 1568 the diocese was merged in that of Meath.

CLONMEL (*Cluain mealla*, or vale of honey), municipal borough and county town of Co. Tipperary, 112 m. S.W. from Dublin, Ireland, a junction on the Great Southern railway (Waterford, Limerick, Thurles), on both banks of the river Suir and on Moore and Long Islands. Pop. (1926) 9,056. It is near fine scenery in the Galtee and Knockmealdown mountains. It is at the head of barge navigation on the Suir. As a walled town (remains are still visible) it was frequently mentioned in the middle ages, but it was dismantled after capture by Cromwell (1650). Bianconi (1815) made it the centre of a system of conveyance of passengers by light cars in south Ireland. The town has a fair agricultural trade, formerly made woollen goods, and is an assize town.

CLOOTS, JEAN BAPTISTE DU VAL DE GRÂCE, BARON VON (1755-1794), better known as ANACHARSIS CLOOTS, revolutionary fanatic, was born near Cleves, at the castle of Gnadenthal, of a noble Prussian family of Dutch origin. His father placed him in the military academy at Berlin, but he left it at the age of 20 and traversed Europe, preaching his revolutionary philosophy as an apostle, and spending his money as a man of pleasure. On the outbreak of the Revolution he went to Paris. On June 19, 1790, he appeared at the bar of the Assembly at the head of 36 foreigners; and, in the name of this "embassy of the human race," declared that the world adhered to the Declaration of the Rights of Man and of the Citizen. After this he was known as "the orator of the human race," by which title he called himself, dropping that of baron, and substituting for his baptismal names the pseudonym of Anacharsis, from the famous philosophical romance of the Abbé J. J. Barthélemy. In 1792 he placed 12,000 livres at the disposal of the Republic—"for the arming of 40 or 50 fighters in the sacred cause of man against tyrants." In September he was elected a member of the Convention, and he voted the king's death in the name of the human race. He was guillotined as an Hébertist on March 24, 1794.

See G. Avenel, *Anacharsis Cloots, orateur du genre humain* (1865).

CLOQUET, a city of Carlton county, Minnesota, U.S.A., on the St. Louis river, 21 m. W. by S. of Duluth. It is served by the Chicago, Milwaukee, St. Paul and Pacific, Duluth and Northeastern, Great Northern and Northern Pacific railways. The population was 5,127 in 1920; in 1930, 6,782 by the Federal census. The river supplies water-power, and the city has large lumber-mills, a pulp and paper-mill and factories making insulating materials, boxes, clothes-pins, toothpicks, broom-handles and other articles of wood. A forest experiment station of the University of Minnesota is located here. The first mill was built in 1878, and the village was named from the French word *claquet*, representing the sound made by the mill. It was chartered as a city in 1903.

CLOSE, MAXWELL HENRY (1822-1903), Irish geologist, was born in Dublin in 1822. He was educated at Weymouth and at Trinity college, Dublin, took holy orders, and held various charges in England. In 1861 he returned to Dublin and devoted himself especially to the glacial geology of Ireland. His paper, read before the Geological Society of Ireland in 1866, on the "General Glaciation of Ireland" is a masterly description of the effects of glaciation, and of the evidence in favour of the action of land-ice. Later on he discussed the origin of the elevated shell-bearing gravels near Dublin, and expressed the view that they were accumulated by floating ice when the land had undergone submergence. He died in Dublin Sept. 12, 1903.

The obituary by Prof. G. A. J. Cole in *Irish Naturalist*, vol. xii. (1903) contains a list of publications and portrait.

CLOSE, a closed place (Lat. *clausum*, shut). In English law the term is applied to land, enclosed or not, held as private property, or to any exclusive interest in land sufficient to maintain an action for trespass. In Scotland the word is used of the entry, including the common staircase, of a block of tenement houses, and in architecture of the precincts of a cathedral or abbey.

The adjective "close" (i.e., closed) is found in several phrases, such as "close time" or "close season" (see GAME LAWS), "close prices" (q.v.); "close borough," one of which the rights and privileges were enjoyed by a limited class (see BOROUGH); "close rolls and writs," royal letters, etc., addressed to particular persons, under seal. (See RECORDS; LETTERS PATENT.)

CLOSED SHOP. A closed shop, in America, is a shop in which trade-union members refuse to allow non-unionists to obtain permanent employment. Shops in which non-unionists are permitted are "open shops." Since 1905 trade-unionists have seriously objected to the use of the term "closed shop." Their contention is that its adoption was due to designing employers aiming to place upon unions the onus of persisting in a policy of arbitrary exclusion. Trade-unions have urged that "union shop" (the English phrase) is the proper descriptive term. Curiously enough both the term closed shop, and its opposite, open shop, have to-day meanings altogether different from their original significance. In the early period of American trade-unions a shop employing exclusively union workmen or observing trade-union rules was regarded as open, one not so restricted a closed shop. After 1889 a reversion of these definitions came into usage.

An Old Institution.—The closed shop is not a development of modern industry. Mediaeval British guilds prevented the working of non-members; so also did, when possible, the eighteenth century trade clubs. Some of the guild regulations of the 16th and 17th centuries decreed that no guild journeyman was to work with a non-member: such principles were an integral part of mediaeval society. These tactics were continued by British trade-unionism and were naturally conveyed to America. The Cordwainers' Society of the City of New York in 1804, the New York Typographical Society in 1809 and subsequently other unions adopted by-laws forbidding members to work for employers hiring men who did not belong to their organizations or who worked for wages lower than the union scale. The chief weapon used by employers until 1836 was the invoking of old laws declaring combinations of workmen and strikes criminal conspiracies. By about the year 1840 the closed-shop rule had been adopted by the majority of American trade-unions, which refused to work with non-union men. These were stigmatized after 1854 as "rats" or "scabs." With the repeal or nullification of conspiracy statutes, employers formed local associations to resist the closed-shop movement.

The Trade-Union Label.—This was a powerful influence by which the American unions gained public support for the closed shop after the year 1880. Agitating for the abolition of sweat-shops, the unions, led by the Cigar Makers' Association of the Pacific coast, succeeded in identifying in the public mind the non-union shop with unwholesome conditions productive of disease. Union propaganda along this line increasingly turned consumers against the purchase of articles not made in union establishments and not bearing the union label. Since 1900 newer laws and the modernizing of many factories have generally caused the abolition of former bad conditions of manufacture. Trade-unions, however, still regard public approval of the union label as pre-eminently essential in their campaign for the union or closed shop. This was shown at the 1926 convention of the American Federation of Labor when the union label trades department reported that by moving pictures and other means it was carrying on an educational campaign which included 36 American States, various Canadian provinces and 396 cities in the United States and Canada.

National Associations Against National Unions.—From 1870 in the United States local trade-unions gradually merged into national unions, the majority of which made the maintenance of the closed shop a vital rule. During the same period, especially in the decade before 1901, there were formed national associations of employers, one of the purposes of which was to maintain the open shop. Large factories locked out union men for demanding the closed shop, the Birmingham Rolling Mill Company did so in 1884; the Granite Manufacturers' Association of Boston in 1887; and the Carnegie Steel Company in 1892. The American Federation of Labor declared in 1890 that the working of union with non-union men was inconsistent, especially when union men displaced unionists locked out or engaged in strike. From 1850 to 1898 the major part of more than a dozen court decisions held that strikes for the closed shop were criminal or tortious. These decisions had no effect upon trade-union insistence for the closed shop.

Conflicts Over "Closed-Shop" Demands.—The struggle over the closed-shop question reached an intense stage in about the year 1901 when the unions insisted upon employers signing written agreements conceding the closed shop. Previously the granting of the closed shop had been based upon custom or oral negotiation. Declaring that they would not admit "union dictation in the management of business," the National Metal Trades Federation and other large employers' associations aggressively campaigned to destroy the closed-shop system.

The award of the anthracite coal strike commission in the great coal strike of 1902 was of most considerable moral help to manufacturers' associations; the commission granted practically every demand of the union except that for the closed shop. Encouraged by this stand, the National Association of Manufacturers in 1902 began a vigorous movement for the open shop. The Citizens' Industrial Association of America, various citizens' alliances in different cities and a number of large corporations did likewise. The American Federation of Labor reiterated that the trade-union movement stood for the strictly union shop. Union after union endorsed the closed-shop principle. The proportion of strikes for recognition of trade-unions and union rules more than trebled in succeeding years. By reducing employment, the panic of 1907 weakened the trade-unions and gave corresponding advantage to employers. The campaigns carried on by the manufacturers' associations also caused a decided shift in public sentiment in favour of the open shop. By 1910 this was established in many industries, notably those which had been consolidated into powerful corporations. The open shop prevailed generally in the South.

The Company Union.—The entry of the United States into the World War in 1917 brought about auspicious conditions for organized labour in abundant employment and high wages. The power of trade-unions seemed secure. But a formidable rival came into existence to thwart the closed-shop plan. This new factor was the formation of company unions entirely distinct from the regular trade-unions. Company unions are those limited to the workers of a particular corporation and are organized under the auspices of the corporation. Some company unions have existed for more than a quarter of a century but only as isolated, unimportant bodies. The noteworthy impetus to their widespread creation came in 1918-19, after which they increased rapidly. The statement was made at the 1926 convention of the American Federation of Labor that the number of wage-earners working under company unions' shop management was more than 2,000,000. The National Association of Manufacturers in 1927 computed the real figure at not more than 1,800,000 and possibly as low as 1,500,000. The American Federation of Labor numbers 2,800,000; the total trade-union organization, including the Railroad Brotherhoods, the Amalgamated Clothing Workers and the Industrial Workers of the World, was in 1927 perhaps 3,700,000. See COMPANY UNIONS.

Much of the discussion at the American Federation of Labor's conventions in 1926 and 1927 was concerned with the matter of company unions. Resolution No. 66 in 1926 declared that the open-shop forces, under the leadership of various associated employers' associations, had organized dual and company unions. These, the resolution held, were artificial creations, and as a menace to the trade-union movement they must be overcome. Voluntary trade-union management co-operating with employers, was suggested as a substitute for company unions controlled by employers. Delegates assailed the "so-called and misnamed American plan" as an un-American one by which employers deliberately sought to bring about industrial serfdom denying freedom of contract and right of choice. In its report to the 1927 convention the executive council of the American Federation of Labor defined the company union as an element which did not make standards; "it is an agency for administering the affairs of a company and is not an economic and social force."

Status of the Closed Shop.—Reports of the U.S. bureau of labour statistics show that strikes for the closed or against the open shop have been few in recent years; of 17,994 labour disputes from 1918 to 1925 inclusive, only 483 dealt with the closed or open shop. A survey prepared by the National Association of

Manufacturers, in Oct. 1927, stated that between 70 and 75% of workers employed in railroad shops were in organizations independent of the American Federation of Labor; that in 185 cities, excluding New York city, 68% of commercial and job printing was open shop; that one or more mechanical departments of 805 English language newspapers were open shop; that the open-shop movement had gained in the bituminous coal industries and had lost in the building trades only. In 1927 the closed shop was still widely established in the clothing trades, but in the automobile industry and in textile factories, particularly in the South, the open shop was so general as to be invariable. Statements made at the American Federation of Labor convention declared that 50% of railroad mileage in the United States was open shop under company union operation; that the metal trades, the printing trades to some degree, and the miscellaneous trades were likewise affected. The National Association of Manufacturers in 1927 estimated that not more than 10% of American industry, both factory and non-factory, was on a strictly closed-shop basis. It vouched for this figure, explaining that, despite union rules, half of the trade-unionists in the United States were actually working under open-shop conditions.

CLOSE PRICES. By reason of the method in which business is conducted on the London Stock Exchange, every security—bond, stock or share—that possesses a free market, is quoted at a double price. At the higher price, the purchaser can expect to buy; at the lower, he is able to sell. Prices quoted in the Stock Exchange Official List, and those in the newspapers, are usually wider than those at which bargains can be effected by either party, buyer or seller. To take the 5 per cent. War Loan as an example, this may be quoted 100½ to 100¾ in the daily Stock Exchange Official List, a margin of 5s. between selling and buying. But the actual dealing price will show no more than 2s.6d. difference. If the market is dull, owing to sellers predominating, the price will probably be 100½ to 100⅝; the buyer pays 100⅝ in this case, the middle price of the official quotation, while the seller receives 100½. Should buyers be in the majority, the price is more likely to be 100⅝ to 100¾, when the seller would get the middle price, i.e., 100⅝. In a quiet market, the price might lie midway between the outside margin of 100½ to 100¾ and be quoted 100⅞ to 100⅞.

The Cause of Close Prices.—The closeness of a price depends entirely upon the amount of business that is doing in a particular stock or share at a particular time. If the Stock Exchange dealer in War Stock finds himself very busy, with brokers coming to deal with him in rapid succession, some as buyers and others as sellers, he can afford to make a closer price than is possible when public business runs at a low ebb. In the first case, therefore, he may make a sixteenth price; say, for example, 100⅝ to 100⅞, feeling reasonably confident that, in the activity shown by the public dealings, he will be able to sell at 100⅞ the stock for which he pays 100⅝. If demand quickens, the price goes up; if stock comes in, the market gives way. Should business fall off, the price widens again. When a stock rarely changes hands, the margin between buying and selling prices may be considerable, because the Stock Exchange jobber, if he sells, may not be able to obtain the stock for some time; if he buys, he runs the risk of not being able to dispose of it. Therefore he makes a wide price by way of insurance against accident, just as he will make a close price when activity of business conditions warrants his doing so.

The Two Factors.—Competition can become so keen in some particularly popular share, or market, that dealers will make extremely close prices. The existence of a market outside London acts as a stimulus to animation and close prices. Bristol has a lively

market, for example, in some of the tobacco shares; Glasgow in J. & P. Coats, chartered, etc.; Paris in Rio Tintos and certain South Africans; Brussels in Brazilian Tractions and Tanganyikas; New York in Canadian Pacifics, and so on. The degree of closeness quoted in any price will expand and contract like a concertina; it is mainly dictated, as previously observed, by the volume of public business, and by competition in the Stock Exchange market concerned.

CLOSURE, the parliamentary term for the closing of debate according to a certain rule, even when certain members are anxious to continue the debate. (See PARLIAMENT: *Procedure*.)

CLOT, ANTOINE BARTHÉLEMY (1793-1868), French physician, known as CLOT BEY, was born at Grenoble on Nov. 7, 1793, and graduated in medicine and surgery at Montpellier. After practising for a time at Marseilles he was made chief surgeon to Mohammed Ali, viceroy of Egypt. At Abuzabel, near Cairo, he founded a hospital and schools for all branches of medical instruction, as well as for the study of the French language; and instituted the study of anatomy by means of dissection. In 1836 he was appointed head of the medical administration of the country. In 1849 he returned to Marseilles, though he revisited Egypt in 1856. He died at Marseilles on Aug. 28, 1868.

CLOTAIRE (CHLOTHACHAR), the name of four Frankish kings.

CLOTAIRE I. (d. 561) was one of the four sons of Clovis. On the death of his father in 511 he received as his share of the kingdom the town of Soissons, which he made his capital, the cities of Laon, Noyon, Cambrai and Maastricht, and the lower course of the Meuse. But he was very ambitious, and sought to extend his domain. He was the chief instigator of the murder of his brother Chlodomer's children in 524, and his share of the spoils consisted of the cities of Tours and Poitiers. He took part in the various expeditions against Burgundy, and after the destruction of that kingdom in 534 obtained Grenoble, Die and some of the neighbouring cities. When Provence was ceded to the Franks by the Ostrogoths, he received the cities of Orange, Carpentras and Gap. In 531 he marched against the Thuringi with his brother Theuderich (Thierry) I., and in 542 with his brother Childebert against the Visigoths of Spain. On the death of his great-nephew Theodebald in 555, Clotaire annexed his territories; and on Childebert's death in 558 he became king of all Gaul. He also ruled over the greater part of Germany, made expeditions into Saxony, and for some time exacted from the Saxons an annual tribute of 500 cows. The end of his reign was troubled by internal dissensions, his son Chram rising against him on several occasions. Following Chram into Brittany, where the rebel had taken refuge, Clotaire shut him up with his wife and children in a cottage, to which he set fire. Overwhelmed with remorse, he went to Tours to implore forgiveness at the tomb of St. Martin, and died shortly afterwards.

CLOTAIRE II. (d. 629) was the son of Chilperic I. On the assassination of his father in 584 he was still in his cradle. He was, however, recognized as king, thanks to the devotion of his mother Fredegond and the protection of his uncle Gontran, king of Burgundy. It was not until after the death of his cousin Childebert II. in 595 that Clotaire took any active part in affairs. He then endeavoured to enlarge his estates at the expense of Childebert's sons, Theodebert, king of Austrasia, and Theuderich II., king of Burgundy; but after gaining a victory at Laffaux (597), he was defeated at Dormelles (600), and lost part of his kingdom. After the war between Theodebert and Theuderich and their death, the nobles of Austrasia and Burgundy appealed to Clotaire who, after putting Brunhilda to death, became master of the whole of the Frankish kingdom (613). He was obliged, however, to make great concessions to the aristocracy to whom he owed his victory. By the constitution of Oct. 18, 614, he gave legal force to canons which had been voted some days previously by a council convened at Paris, but not without attempting to modify them by numerous restrictions. He extended the competence of the ecclesiastical tribunals, suppressed unjust taxes and undertook to select the counts from the districts they had to administer. In 623 he made his son Dagobert king of the Austrasians, and gradually

subdued all the provinces that had formerly belonged to Childebert II. He also guaranteed a certain measure of independence to the nobles of Burgundy, giving them the option of having a special mayor of the palace, or of dispensing with that officer. These concessions procured him a reign of comparative tranquillity. He died on Oct. 18, 629, and was buried at Paris in the church of St. Vincent, afterwards known as St. Germain des Prés.

CLOTAIRE III. (652–673) was a son of king Clovis II. In 657 he became the nominal ruler of the three Frankish kingdoms, but was deprived of Austrasia in 663, retaining Neustria and Burgundy until his death.

CLOTAIRE IV. (d. 719) was king of Austrasia from 717 to 719. (C. Pf.)

CLOTH, any material woven of wool or hair, cotton, flax or vegetable fibre. In commercial usage, the word is particularly applied to a fabric made of wool. The word is Teutonic, though it does not appear in all the branches of the language. It appears in German as *Kleid* (*Kleidung*, clothing), and in Dutch as *kleed*. The ultimate origin is unknown; it may be connected with the root *kli*—meaning to stick, cling to, which appears in “clay,” “cleave” and other words. The original meaning would be either that which clings to the body, or that which is pressed or “felt” together. The regular plural of “cloth” was “clothes,” which is now confined in meaning to articles of clothing, garments, in which sense the singular “cloth” is not now used. For that word, in its modern sense of material, the plural “cloths” is used. This form dates from the beginning of the 17th century, but the distinction in meaning between “cloths” and “clothes” is a 19th century one. A curious employment of the word is in the clerical profession, its members often being spoken of as belonging “to the cloth.” (See WOOL, COTTON, etc.)

CLOTH FINISHING. In this article, the subject of finishing is treated under the two headings (1) Cotton and (2) Wool.

Reference should also be made to the article COTTON AND COTTON INDUSTRY, Section VI., Subsection D.

COTTON

The finishing of cotton fabrics was originally the final operation performed on the fabrics to make them ready for sale. In its modern significance, finishing comprises a large and diverse range of processes intended to produce in the fabric a desired appearance or feel; and the machines required for this purpose are correspondingly numerous and varied; finishing operations require

plant for, to name some of the important processes, shearing, stretching, drying, damping, pressing, embossing, impregnating, covering and raising cotton cloths.

Classification of finishes in relation to the many different kinds of cotton fabrics is difficult, because many of the processes are applicable to a wide range of cloths. They may be considered under the following headings:— Grey goods, *i.e.*, cloth direct from

BY COURTESY OF MATHER AND PLATT, LTD.

FIG. 2.—THREE-BOWL FINISHING CALENDER ARRANGED TO GIVE A BRIGHT FINISH ON BOTH SIDES OR A GLAZED SURFACE ON ONE SIDE ONLY

the loom; white goods, *i.e.*, cloth which has undergone a bleaching process; plain dyed goods—colours and black; printed goods; raised goods.

The greater number of processes of finishing cotton goods are empirical in character; the underlying physical and chemical changes are not fully understood. A finish produced in one works may be impossible to reproduce in another works, although the same kind of plant and mixings are being used. Even in the same works, two apparently identical machines will give appreciably different results. This is not to say that finishing is a matter of chance; there are very wide differences between the various classes of finish which differences are definable in terms of plant and mixing.

The following gives some idea of the finishing machines used for the different qualities set out above:—

Grey Goods.—These may be finished pure, *i.e.*, without any additional size or stiffening. After passing through a shearing machine or a combined moting and shearing machine, the cloth may be conditioned in a damping machine of the brush type or the spray type (fig. 1) and afterwards calendered in a suitable calender, such as the three-bowl swissing calender (fig. 2) or a five or seven bowl calender arranged to give a bright finish on both sides of the cloth, or a friction calender giving a glazed surface on one side only. Grey goods which are stiffened before being calendered are passed through a range comprising a mangle and cylinder drying machine (fig. 3). The mangle may have two or three bowls, and the drying set may be horizontal or vertical.

Coloured woven goods, *i.e.*, woven from grey bleached and dyed yarns, may be treated in a manner similar to the grey, making use of the same kind of machinery. Both grey and coloured woven goods may be run through the clip-stretching machine with the object of recovering width, or straightening weft, or improving the feel by breaking down the hardness produced in an earlier process, or lifting the figure of the original weave.

White Goods.—Here there are a very wide range of finishes requiring very extensive plant; for example

- Pure finish (without stiffening); these may, or may not be calendered or beetled.
- Finishes requiring impregnation of the cloth with the stiffening mixture.
- "Back-filling," that is, the stiffening is applied to the back of the cloth only.

White goods are generally passed through a water-mangle with the object of improving the appearance of the cloth, closing up the threads after the bleaching process, and preparing it for the filling mixture. After mangling, the cloth is dried on an ordinary cylinder machine (fig. 4) or for twills or figured goods, additional rollers or winces are added so that the face side does not come in contact with the cylinders. White goods are usually starched in conjunction with the drying machines, as for grey, coloured woven, dyed and printed goods. Various types of starch mangles are used for this purpose; the two-bowl mangle shown in fig. 5; the two-bowl friction calender (fig. 5) by which the filling can be forced into the cloth; the back-filling mangle.

After starching or filling, the cloth is dried over a cylinder drying machine, back-filled goods being dried over machines with the modification referred to which permits of only one side of the cloth coming in contact with the metal. Or instead of cylinder-drying, the cloth may be dried on a hot-air stentering range. The starch mangle shewn in this illustration is not usual in this combination in white-finishing. By this method, any lost width may be recovered, the feel of the cloth is better, and an elastic finish may be produced by the jiggling motion of the stenter, and any weft-distortion may be corrected.

The further processes may involve the use of the damping machine (fig. 1) and various calenders similar to those given for grey and coloured finishing and possibly the beetling machine.

BY COURTESY OF MATHER AND PLATT, LTD.

FIG. 3.—HEAVY FINISHING RANGE WITH VERTICAL DRYING MACHINE

Plain Dyed Goods.—These also require a great variety of finishes, but the range of machines used is not so great as in the case of white goods, for instance, back-filling and friction starching is rarely employed with dyed goods. Three and four bowl water mangles are employed and a drying from these machines is generally effected on drying cylinders. The stiffening of dyed goods is carried out on a two-bowl mangle and cylinder drying machine, or preferably on a hot-air stentering range, for example, mangle cylinders and goft. stenter with hot-air drying. Damp- ing machines, stretching machines, breaking machines, calenders

from three to seven bowls with and without friction may be required, for certain finishes; for producing window blinds beetles are required; Schreiner calenders for silky finishes and embossing calenders for book cloths, etc.

Printed Goods.—These are finished on similar machines to those used for dyed goods. For ordinary stiffening or starching a range comprising a two-bowl starch mangle, followed by a

BY COURTESY OF MATHER AND PLATT, LTD.

FIG. 4.—VERTICAL DRYING MACHINE ON THREE PAIRS OF UPRIGHTS; FOR DRYING CLOTH AFTER MANGLING

cylinder drying machine is employed, or a hot-air stentering range consisting of a two-bowl mangle, six-cylinder drying machine and goft. stenter with hot-air drying. For muslins, voiles and goods requiring an elastic or batiste finish, the latter method is indispensable. Another method of stiffening known as back starching, differs from the ordinary method, in that the starch paste is applied to the back or unprinted side of the fabric by means of a brass roller partly immersed in the starch box. The drying of back starched cloth is performed by passing the cloth over the drying cylinders of large diameter, say, from 5 to 7 feet, arranged in such a manner that the starched side does not come in contact with the heated cylinders. An ordinary drying machine can be employed, but in this case, precautions have to be taken by cooling the first cylinders to prevent the starched side adhering to the cylinders. Fig. 5 shows a universal starch mangle for ordinary starching, slop starching and back starching. A back starcher or universal starcher can be used in conjunction with a hot-air stenter instead of the usual cylinder drying machine. The additional machines which may be required for finishing printed goods are similar to those already mentioned, and include clip-stretchers, swissing and friction calenders, Schreiner calenders, beetles, as for dyed goods.

Raised Goods.—In this class are included those cloths which are raised on one or both sides, such as flannelettes. Similar machines to those employed for dyed goods are used for the actual finishing, the stiffening being carried out on a mangle and drying machine, or hot-air stentering range. The conditioning clip stenter is especially useful. Calenders are not usual, brushing and lustring machines being used instead.

WOOLLEN GOODS

The finishing of woollen goods requires in general plant and processes entirely different from those described in connection with cotton. The methods employed naturally vary with the nature of the fabric: for example, worsted fabrics (woven from yarns produced from the longest staple fibre, and containing the

maximum of parallelism between the fibres) require in general a "clearer" finish than woollen fabrics woven from yarns composed of interlaced fibres of all lengths, which lend themselves to milling and raising. In the former case, the characteristics of the fabric structure dependent upon the nature of the weave are largely retained, and even developed, whilst in the latter case the thready appearance of the loom state fabric often gives way to a felted effect in which the individual warp and weft threads are no longer discernible, the change being usually accompanied by an increase in density and a corresponding decrease in width and length of the fabric. In wool goods, "finishing" covers all the processes undergone by the fabric after leaving the loom. There are certain preliminary operations to which the piece is subjected before the finishing process proper, which are intended to correct weaving faults and yarn defects. The pieces are "perched" over a bar or roller usually in a north light and examined by the eye and by hand feeling. "Knotting" consists in removing knots from warp or weft by first drawing these through to the back of the cloth, after which they are cut away. "Mending" or "darning" is the process of correcting defects such as holes and missing yarn (short ends and picks) by inserting new threads correctly interlaced in accordance with the weave structure. The finishing processes proper divide themselves into the two groups of wet and dry operations.

Wet Operations.—These include crabbing, scouring, milling, tentering and carbonizing.

Crabbing. The object of this process is to "set" the fabric, *i.e.*, to obviate the risk of distortion in subsequent processes. The piece is tightly wound in a stretched condition over a perforated roller, on which allow steam or hot water or both to be forced through the piece. The combined effect of moisture and heat is to render the wool fibre plastic, and in this condition the internal strains in the fabric which might produce cockling in a subsequent

BY COURTESY OF MATHER AND PLATT, LTD.

FIG. 5.—TWO-BOWL STARCH MANGLE

wet process are released, and on cooling the fabric assumes a more or less permanent "set."

Scouring. This process is intended to remove grease and oil and mechanically adhering dirt from the wool goods. The detergents used are either soaps or alkalis depending upon the amount and character of the oil present in the wool. Some fabrics are conveniently scoured in the rope-form, whilst others—*e.g.*, those liable to crease, are best scoured in the open width.

Milling. This process makes use of a special property of the woollen fibre of "felting." The woollen cloth is impregnated with a solution of soap (more rarely of acid) and subjected to pressure

between rotating rollers in the milling machine, or by the action of fallers in the stilling stocks. As a result of this action, the fibres become matted or felted if the milling is carried far enough, the warp and weft threads appear to lose their identity, and the woven structure of the cloth is entirely hidden. The cloth often gains strength as a result of milling, whilst the density is increased at the expense of the width and length, the whole fabric being rendered more consistent.

BY COURTESY OF MATHER AND PLATT, LTD.

FIG. 6.—FRICTION STARCH MANGLE

Tentering. After the scouring process, the pieces may be dried by first removing the excess of water by hydro-extracting or by passing through the wringer; and afterwards subjecting to the drying action of warm air whilst stretched out between the lists or edges. In addition to drying the pieces, this operation straightens and "sets" the cloth.

Carbonizing. Some kinds of wool fabrics, *e.g.*, velours, may be produced from low quality wools containing vegetable matter. This impurity may be removed by soaking the fabric after scouring in a solution of sulphuric or other acid, drying, and raising to a temperature of about 100° C, when the vegetable matter is disintegrated and may be removed by a slight beating and air draught.

Dry Operations.—These include raising, cutting, napping, blowing, brushing, steaming and pressing.

Cutting. This operation formerly performed by hand with large shears is now carried out on a suitable machine. It consists in removing the pile of the fabric beyond a certain length, this length varying greatly with the class of fabric. For example, worsted cloths are cut close to the surface in order to enhance the effects of weave and colour. Woollen fabrics only receive as a rule a cutting sufficient to level up the projecting fibres.

Blowing consists in subjecting the pieces wound in the open width on a perforated beam to the action of steam. There is some resemblance to the crabbing process already described, and the object is again to "set" the fabric permanently, though other advantages are also usually obtained, such as increase in the lustre of the fabric.

Steaming differs from the blowing process in that the fabric is drawn from one roller to another over a box with perforated top from which steam issues. The object is to raise the fibre somewhat, and thus destroy any glaze, and to soften the feel or handle as a result of the conditioning effect of the steam, *i.e.*, by the absorption of moisture.

Raising. This is a mechanical operation in which fibres are lifted from the yarns in the cloth, or from the surface to produce a pile or nap. The raising process was formerly effected by the use of teazles (*Dipsacus fullonum*) applied by hand; and teazles are still used, mounted on cylinders and operated by power. In addition, cord-wire raising is now largely practised; in this form a number of raising rollers are covered with cord clothing, and revolve against the cloth which is made to pass over them by an independent motion.

Pressing is an important operation in the finishing of wool goods; it may be carried out with the object of smoothing the surface of the fibre and imparting an appearance of uniformity, or by prolonged treatment the lustre of the fabric may be greatly increased. The fabric, charged with a sufficient amount of moisture, is subjected to the combined action of (usually) heat and hydraulic pressure. Three different systems are used, (a) the vertical hydraulic press, (b) the intermittent hydraulic press, (c) the rotary press.

Shrinking. The tendency of wool garments to contract in wear is well-known. The object of the shrinking process is to bring out this contraction in dimensions before the garment is made up. It is usually effected by thoroughly wetting the material, and redyeing it at a low temperature, after which a mild pressing treatment is applied to remove creases, etc. There are many names for varieties of this "shrunk finish"; perhaps the best known being "the London-shrunk finish."

Not all the above processes are utilized in finishing a particular class of wool fabric. Worsted cloths in the main undergo the series of operations known as the clear-cut finish. These cloths include fancy vestings and suitings, striped trouserings, costume cloths and dress fabrics, fancy worsteds, etc. A finishing routine for the latter involves knotting and mending, crabbing, scouring, tentering, brushing and steaming, cutting, blowing and pressing.

CLOTHIER, a manufacturer of cloth, or a dealer who sells either the cloth or made-up clothing. In the United States the word formerly applied only to those who dressed or fulled cloth during the process of manufacture, but now it is used in the general sense, as above.

CLOTHIERS, WHOLESALE. The term Wholesale Clothiers is applied to the makers and distributors of "ready-to-wear" or "machine-made" woollen and other types of outer clothing for men and women, comprising suits and overcoats for men, costumes, dresses, skirts, and coats for women. The industry now forms the more important of the two divisions—wholesale and made-to-order—of the tailoring, or clothing trades.

The name "clothier" signified in the days of handloom weaving, the master cloth-maker or producer, but with the advent of the power-loom that designation gradually became changed to "manufacturer," prefixed generally with a qualifying name indicative of the class of fabric made, such as "cloth," woollen," or "worsted." Some makers, however, prefer to style themselves manufacturing clothiers. In America, the cloth dresser (finisher), or fuller was formerly termed a clothier.

CLOTHING MANUFACTURE. The application of the sewing-machine to tailoring made the production of ready-made clothing possible in bulk. The early demand for ready-made clothing may be traced to the older seaport towns, where such clothing was often required at short notice by persons returning from long voyages. The foundations of the wholesale clothing industry, however, may be said to rest first, on the invention of the sewing-machine; and secondly, upon the introduction of cheap (shoddy) cloth made from pulled-up rags, from which material machine-made clothing, produced in bulk, was originally made. The use of shoddy has practically disappeared, however, and the finest grades of cloth are quite generally used by the best manufacturers of ready-made clothing, who are also in a position to employ highly qualified designers.

Thimmonier's Sewing Machine.—Ready-made clothing was first made in Paris by a tailor named Thimmonier, who invented the first sewing-machine in 1830, and applied it with considerable success to the production of army clothing until 1841, when his factory was destroyed during a machinery riot. Thimmonier afterwards went to England with an improved machine which he

patented in 1848. This, however, met with no success, and it was not until 1851, when the American invention of Isaac Merritt Singer was introduced into England, that the industrial potentialities of the sewing-machine were realized.

The quicker output obtained by mechanical sewing necessitated an increase in the speed of pattern cutting, and 1860 saw the invention of the cloth-cutting band-knife (based on the principle of the band-saw), which solved the problem of supplying material to keep pace with the work of the sewing-machine. This machine was made in Leeds by Messrs. Greenwood and Batley at the suggestion of Mr. (afterwards Sir) John Barran, a native of London who had settled in Leeds some years previously, where he had commenced the wholesale clothing industry in 1855. The modern machine has a knife velocity of 7,000 ft. per minute, and can cut 50 thicknesses of cloth at once. A more modern style of machine still is a portable knife-cutter worked by electricity.

Other inventions, mostly in connection with sewing, followed in rapid succession; and sewing by hand for joining most parts of a garment is now almost entirely superseded by machines devised for such special purposes as felling (*i.e.*, turning over the edges of the cloth and then sewing in order to prevent fraying), sleeving, button-hole making and button stitching. A machine for marking the outlines of the patterns to prepare them for cutting, and machines for pressing have assisted further to reduce handwork to a minimum; and the transition from operating the sewing-machines by hand or foot to power driving has contributed to greatly increased output and cheaper production.

Division of Labour.—The modern factory system is highly sectionalized, and its production and output depend upon an extraordinary degree of subdivision of labour; so much so, that a coat, in making, may pass through the hands of as many as 50 persons. Subdivision of labour reduces the cost of production by causing the simpler processes to be effected by the unskilled labour of young persons, and utilizing skilled labour only for the more complicated work.

The system originates with the designing and production of the patterns in the various standard sizes by the head pattern or stock cutter, who is responsible for keeping in touch with movements in fashion and "style." The separate paper pieces comprising a pattern for a garment or suit are then formed into what is termed a "lay" by fitting them as closely together as possible (interlocking them after the manner of a jig-saw puzzle), so that in cutting out the cloth there will be a minimum of waste; the operation being termed "lay-getting." The outlines of the lay are chalked on a large piece of tough paper or linen corresponding in width to the cloth, and then these are perforated by a machine called a "process-marker," thus forming the pattern or lay from which the garments are cut in bulk. To prepare the cloth for mechanical cutting, it is automatically folded in the number of lengths required by the "laying-up" machine; the lay is placed on the top fold, and specially prepared powdered chalk is rubbed through the perforations to indicate the lines to be followed by the knife. After cutting, the pieces for each individual garment are sorted out and numbered, tied into bundles with their necessary trimmings, which have been prepared in a similar manner to that just described, and passed forward to the factory for making up. Here, the various parts are sewn and gradually assembled into the complete garment—this being a combination of hand and machine work by trimmers, finishers, machinists (who work the specialized sewing-machines) and pressers.

The industry has been built up in Great Britain very largely by the exploitation of alien Jewish labour, and in fact, the origin of the subdivisional system of work was the outcome of the necessity for finding employment for the great influx of Russian Jews to London. These unfortunate people, usually carried on their occupation at home, and by reason of their poverty and consequent low standard of living worked for very low rates of payment. This quickly resulted in the "sweated labour" conditions, exposed by Charles Kingsley and other social reformers. In 1909, when the first Trade Board act was passed, ready-made and wholesale bespoke tailoring was classed among the four industries having "rates of wages exceptionally low as compared

with those in other employments." The Tailoring Trade Board was established under this act in the following year with powers to determine the minimum rates of wages in all branches of the tailoring trades, and in 1920 two separate boards were constituted—one to deal with the ready-made and wholesale section, and the other to control the retail bespoke section of the industry.

Location of Industry.—Though London was the original home of the British ready-made clothing trade, Leeds is now the chief seat of the industry, and wholesale clothing with its 400 firms providing employment for over 30,000 persons forms the premier trade in the city. There is a difference, too, in the conduct of the industry in the two centres; in Leeds it is almost entirely confined to work in the factory; in London, "outworking" persists to a large extent. Leeds was the first provincial town (in 1855) to engage in the industry, and no doubt owes its present leading position largely to its advantageous geographical situation in the centre of the West Riding of Yorkshire woollen and worsted cloth manufacturing area, which supplies it with all classes of fabrics from the lowest to the highest in quality. The manufacture of clothing is also carried on in the Huddersfield and Hebden Bridge districts, Liverpool and Manchester, Bristol, Colchester, and Leicester; and in Scotland, Glasgow is now an important centre. There are nearly 6,000 firms in Great Britain with a personnel of over 200,000 persons.

It may be noted here that though ready-made clothing was identified formerly with inferior materials only, this is no longer the case, and there is now a large and increasing demand for "ready-for-service" (to use the latest description) garments of high class workmanship, made of the finest quality materials.

With regard to markets, it is generally considered that about two-thirds of the yearly British output is absorbed at home, and the remainder goes principally to the British colonies, though the United States of America is a considerable customer for the best class of British goods in spite of her own high standing in the industry.

There are two associations of British employers: (1) the Wholesale Clothing Manufacturers' Federation (founded in 1910) which has its headquarters in London, and local branches in all clothing centres; and (2) the Northern Clothing Manufacturers' Association which has its chief office at Leeds. Employees are represented by the Tailors' and Garment Workers' Union of Leeds and London and other organizations.

Technical education is provided for at the Leeds Technical college (both day and evening courses), and also by the London County Council.

(A. Y.)

United States.—Clothing manufacture in the United States has passed largely out of the hands of the merchant tailor and was in 1928 conducted in modern plants equipped with labour saving machinery. It has been estimated that between 80 and 90% of the men's clothing made in the United States is of the "ready-to-wear" type. Most of this clothing is produced in the centres of population, although in recent years there has been some migration of factories to smaller cities in order to reduce production costs by cheaper labour and lower factory rental costs. New York city is the most important clothing market, making about 40% of the total clothing produced in the country. Many out-of-town factories maintain sales offices in the metropolis. Other important clothing centres are Chicago, which produces about 15% of the total volume for the country, Cincinnati, St. Louis, Philadelphia, Boston, Buffalo and Rochester.

In New York city the greater part of the clothing is produced under the "contract" system. The manufacturer cuts up the cloth into the various patterns he desires and this cloth is sent to a contractor for fabrication into garments. This system partly accounts for the large number of clothing firms in New York city, for it enables a person to enter the business with comparatively small capital. In the other clothing centres the "contract" system of production is carried on only to a small extent, most of the clothing manufacturers maintaining their own factories.

The success of mass production in the clothing industry in the United States that has developed since the 20th century began,

rests upon (1) scientific pattern construction; (2) highly efficient labour saving machinery; (3) effective factory arrangement; (4) high division of labour; (5) economies effected in the purchase and fabrication of materials on a large scale, and (5) standardization of styles. The industry did not make any great progress until scientific investigations of average proportions of the human body yielded sufficient information on which to base the present art of clothing designing. Experience has disclosed that normal proportions and variations therefrom are fairly constant in any group of 100 men, and consequently, clothing manufacturers make their garments in assortments complying with such experience. For a retail store carrying 500 suits, some manufacturers recommend the following assortment: 45% regular; 6% long; 13% short; 2% extra short; 8% stout; 3% short stout; 2% long stout; 4% portly; 2% long portly; 3% short portly; 3% forward; 3% young stout; 3% stalwart; 2% corpulent. All stores do not carry, nor do all factories make assortments as complete as above. However, the more complete the range of sizes, the less alterations, or busheling, must be made. These busheling operations are standardized, and because of the high development of the art of making ready-to-wear clothing in the United States, changes are usually slight.

In making a new model sack-coat or overcoat, the designer visualizes the style he wishes to create and drafts a pattern, usually size 36. This pattern is used to derive a complete set of patterns for all required sizes, including regulars, shorts, longs, stouts, etc. This work of translating the basic pattern into other sizes is called "pattern grading." Considerable skill and experience is naturally required for successful clothing designing. In many American factories the designer not only designs the models, but he also supervises the general production of the garments in the factory.

Two methods of cloth shrinking, or sponging, are in use: the cold water, or London process and the decatizing method. Cloth shrunk by the London process is passed through a vat of water and hung in folds on rods to dry. This method is used chiefly for worsteds and serges. Most of the fabrics used for clothing manufacture in the United States are treated by the decatizing method. The cloth is wound on a metal cylinder perforated by many small holes through which steam emerges and passes through the cloth. After remaining on the cylinder for about three minutes the cloth is wound on a roller and allowed to dry. Some houses treat all their fabrics by this method, which, while not as good as the London method, is rapid and less expensive. Less shrinkage results from decatizing than from the use of the London method. The extent of shrinkage depends upon the type of fabric and method of shrinkage, ranging from 3 to as high as 8 or 9%.

After the cloth has been shrunk and dried, it is laid out on cutting tables in "lays" from a few thicknesses of cloth to as high as 50 or 60 in the case of work clothing. The cardboard patterns are laid on the cloth in such a manner as to conserve every possible inch of cloth. After the outlines of the patterns are chalked on the top layer of the lay the outlines are cut by electric cutting machines. These machines are of two types; the one having a revolving disk cutter and the other having a vertical blade moving up and down. The great amount of labour saved from this method of cutting is difficult to estimate. In even a small establishment thousands of garments may be cut from a single pattern.

Most cutting rooms are located on the top floor of the factory so that the cloth after cutting can pass through the assembly departments to the stock room by means of gravity or other conveyors. The factory is usually laid out so that each operation follows in sequence to avoid unnecessary handling of the garments. The pieces of cloth are tied together and they are then distributed to the coat, the vest and the trousers departments. Usually one-half of a garment is made in one section of the department and the two completed halves are finally joined together. Division of labour is carried out to a very high degree. Each operator performs but one task on a garment, thereby gaining unusual proficiency. In the making of some pockets, for example,

STEPS IN THE PROCESS OF CLOTHING MANUFACTURE

1. Examining cloth for imperfections before starting the manufacturing
2. Machine which finishes the fabric. After the material has been shrunk it passes through this machine, which sets it and gives to it the proper finish
3. Cutting the material. A view of the rooms where suits are being fashioned
4. Electric knives used to cut the linings for the clothes. With these devices a large number of linings are cut at the same time
5. Tailoring the garments. Shop where the clothes are sewn and finished models are examined as to quality in workmanship
6. Pressing the garments, showing one of the many pressing operations which a suit receives in the tailor shop

there are 13 different operations, each one of which is performed by a single individual. One hundred persons may work on a sack coat. Not only does an operator do more work under this system, but because of the skill he develops, he does better work. This high division of labour also permits the use of workers possessing ordinary intelligence. Practically all clothing factories in the United States operate on a piece work basis; *i.e.*, a unit price is fixed for each operation on a garment.

Much labour saving machinery for the clothing industry has been perfected in the United States, by means of which the various operations are speeded up and the unit costs reduced. Dozens of improved types of sewing machines have been introduced which are very instrumental in reducing costs. The late models of button-hole machines cut the cloth, sew and tack the buttonhole in a fraction of a minute. Buttons are sewed on by machine and seams in trousers are pressed by an ingenious device in a quarter of the time required by hand. One of the outstanding developments in labour saving machinery is the steam pressing machine. In establishments making higher grades of clothing, the garment is pressed after each important operation. The steam pressing machine now in use is made in a variety of models having bucks shaped to fit various parts of the garment. The garment to be pressed is placed on the buck, which is canvas-covered, and a counter-balanced canvas-covered block, hinged to the frame supporting the buck, is pressed down on the garment. Steam is forced through the garment. This steam is usually drawn away by means of a vacuum system. The steam pressing machine has very materially lowered clothing pressing costs. All operations, however, are not performed by machinery. Some hand-work is required on all ready-to-wear clothing, and as many as 20 or more operations are done by hand on higher priced ready-to-wear garments.

Another factor that has had an important influence in stabilizing and reducing waste in the clothing industry in the United States is the semi-annual style forecast prepared by the International Association of Clothing Designers. Conventions are held in January and July each year by the association and proposed models for the following season are exhibited, from which the style forecasts are prepared. These forecasts serve as a guide for designers and tend to standardize styles for each season. This permits manufacturers to concentrate production on salable models, and at the same time does not eliminate the element of style.

The manufacture of men's clothing is one of the important industries in the United States. According to the last report of the U.S. bureau of census (1925) there were 4,000 clothing establishments reporting to the bureau. These had 174,332 workers and the value of their products for 1925 was \$1,087,238,000. (C. Læ.)

CLOTILDA, SAINT (d. 544), daughter of the Burgundian king Chilperic, and wife of Clovis, king of the Franks. On the death of Gundioc, king of the Burgundians, in 473, his sons Gundobald, Godegisil and Chilperic divided his heritage. At Lyons an epitaph has been discovered of a Burgundian queen, who died in 506, and was most probably the mother of Clotilda. Clotilda was brought up in the orthodox faith. Her uncle Gundobald was asked for her hand in marriage by the Frankish king Clovis, who had just conquered northern Gaul, and the marriage was celebrated about 493. On this event many romantic stories, all more or less embroidered, are to be found in the works of Gregory of Tours and the chronicler Fredegarius, and in the *Liber historiarum Francorum*. Clotilda did not rest until her husband had abjured paganism and embraced the orthodox Christian faith (496). With him she built at Paris the church of the Holy Apostles, afterwards known as Ste. Geneviève. After the death of Clovis in 511 she retired to the abbey of St. Martin at Tours. In 523 she incited her sons against her uncle Gundobald and provoked the Burgundian war. In the following year she tried in vain to protect the rights of her grandsons, the children of Clodomer, against the claims of her sons Childebert I. and Clotaire I., and was equally unsuccessful in her efforts to prevent the civil discords between her children. She died in 544, and was buried by her husband's side in the

church of the Holy Apostles.

There is a mediocre *Life* in *Mon. Germ. Hist.: Script. rer. Merov.*, vol. ii. See also G. Kurth, *Sainte Clotilde* (2nd ed. 1897). (C. Fr.)

CLOUD, a mass of condensed vapour, either liquid or solid, hanging in the air at some height from the earth (from the same root and probably the same word, as "clod," common to Teutonic languages in various forms meaning a mass or lump; it is first applied in the more usual sense in the late 13th century; the Anglo-Saxon *clūd* is used only for "a mass of rock," *wolcen* being the A.S. word for "cloud"). This accepted definition rules out fogs and creeping mists from any classification.

Classification of Clouds.—It is reasonable to suppose that the shapes and general appearance of clouds must have been a matter of interest and speculation from earliest times. The classical writers make use of a variety of expressions for cloud forms but as no systematic early classification is known it becomes necessary to translate such expressions in general terms. Theophrastus of Erusus (*c.* 373–286 B.C.) in his *Book of Signs* (trans. J. G. Wood, 1894) certainly distinguishes "streaks of clouds" from "clouds like fleeces of wool" and uses the distinction in his weather prognostications, but the classification does not appear to have been developed. The field remained open until the 19th century when the famous French biologist Jean Baptiste, Chevalier de Lamarck, in the course of his pioneer work in weather-mapping (1801–04), made use of a scheme of cloud classification. Lamarck's climatological work was ill-appreciated in France and but little known elsewhere. In 1803 Luke Howard published his "On the modifications of clouds" in *Tilloch's Philosophical Magazine*. This was an entirely new and independent scheme in which the terms were all Latin, and were applied with such excellent judgment that his system remains as the broad basis of those in use to-day. He named three primary types of cloud—Cirrus, Cumulus and Stratus—and proposed four additional compound forms—Cirro-cumulus, Cirro-stratus, Cumulo-stratus and Cumulo-cirro-stratus or Nimbus. Thomas Forster in his *Researches about atmospheric Phenomena* (1813) gives Howard's classification and suggests English names for the various types, *e.g.* cirrus becomes curlicloud; cumulus, stackencloud; stratus, fallcloud, cirro-cumulus, sondercloud; cirro-stratus, wanecloud; cumulo-stratus, twaincloud and nimbus becomes raincloud. Howard's scheme was universally adopted, in fact, his cirrus and cumulus are the clouds still known by the same names, though his stratus which seems to have been fog, has now been given a different meaning. His compounds were modified subsequently and further subdivisions were made, which involved the use of new terms. Many new terms failed to establish themselves either because the need for the new term was not widely accepted or because the author's definition of the name was not precise enough to give his exact cloud type. Other names such as A. Poe's *pallium* to signify a uniform sheet have been fairly generally adopted. Notwithstanding the obvious importance of Howard's original paper it was either disregarded or not known to several later writers, for example, The Rev. W. Clement Ley does not refer to it though in his remarkable book *Cloudland* (1894) he describes an entirely new scheme. Instead of a classification based on the appearance of clouds, four different groupings are made which depend upon the processes of cloud formation, *viz.*: (1) Clouds of Radiation, chiefly fogs. (2) Clouds of Interfret, chiefly stratus. (3) Clouds of Inversion, cumulo and nimbus types. (4) Clouds of Inclination, chiefly cirro forms. Ley's definitions of his terms are that interfret comprises the interaction of two currents on one another, which currents differ in velocity or direction or both. Inversion is merely vertical convection while inclination supposes that the ice particles are falling through currents of air which have a progressive change of velocity and so draw out the crystals into the characteristic wisps and bands of the cirrus types. Modern research has proved that Ley's explanations of his interfret and inclination types are inadequate, while his radiation types are best grouped as fogs. Nevertheless his ingenious scheme possesses elements more in accordance with some desirable future scientific classification than any which preceded it, but such a scheme cannot be adopted until meteorologists are in more general agreement as to the complicated processes involved

in cloud formation.

For the purpose of other than local weather charts it was soon realized that some internationally accepted scheme had to be evolved. For many years after the institution of the International Meteorological Organization considerable attention was given to the matter and constructive proposals were contributed by a host of workers including Ley, Rotch, Mohn, Riggenbach, Teisserenc de Bort, Abercromby and Hildebrandsson. The last two meteorologists had suggested a modification of Howard's classification which differed chiefly in the introduction of a new class, which they distinguished by the use of the prefix *Alto*. Their scheme was formally adopted at the Munich International Meteorological Conference of 1891, and a committee was appointed to draw up an atlas showing the exact forms typical of each variety considered. Finally in Aug. 1894 a small sub-committee consisting of Hildebrandsson, Riggenbach and Teisserenc de Bort was charged with the task of producing the atlas. This was issued in 1896 and a second edition by Hildebrandsson and Teisserenc de Bort was published in 1910. The *International Cloud Atlas* has ten principal forms of cloud which are included in the code of telegraphic reports on cloud forms.

- A. *Upper clouds*, average altitude 9,000 metres.
 1. Cirrus.
 2. Cirro-stratus.
- B. *Intermediate clouds*, between 3,000 metres and 7,000 metres.
 3. Cirro-cumulus.
 4. Alto-cumulus.
 5. Alto-stratus.
- C. *Lower clouds*, 2,000 metres.
 6. Strato-cumulus.
 7. Nimbus.
- D. *Clouds of Diurnal Ascending Currents*.
 8. Cumulus, apex 1,800 metres, base 1,400 metres.
 9. Cumulo-nimbus, apex 3,000 to 8,000 metres, base 1,400 metres.
- E. *High Fogs*, under 1,000 metres.
 10. Stratus.

Shaw's definitions of these forms in the *Manual of Meteorology*¹ (1926), differing slightly from those given in the second edition of the Atlas, may be summarized as follows:

1. *Cirrus* (Ci.).—Detached clouds of delicate appearance, fibrous (thread-like) structure and feather-like form, generally white in colour.

2. *Cirro-stratus* (Ci. S.).—A thin sheet of whitish cloud sometimes covering the sky completely and merely giving it a milky appearance; it is then called cirro-nebula or cirrus haze; at other times presenting more or less distinctly a fibrous structure like a tangled web. This sheet often produces halos around the sun and moon.

3. *Cirro-cumulus* (Ci. Cu.).—A mackerel sky with small rounded masses or white flakes without shadows, or showing very slight shadow; arranged in groups and often in lines. (See Plate II. fig. 3.)

4. *Alto-cumulus* (A. Cu.).—Larger rounded masses, white or greyish, partially shaded, arranged in groups or lines, and often so crowded together in the middle region that the cloudlets join. (See Plate II. fig. 4.)

5. *Alto-stratus* (A. S.).—A dense sheet of a grey or bluish colour sometimes forming a compact mass of dull-grey colour and fibrous structure; at other times thin like the denser forms of No. 2. (See Plate I. fig. 1.)

6. *Strato-cumulus* (S. Cu.).—Large lumpy masses or rolls of dull grey cloud, frequently covering the whole sky, especially in winter. It may be distinguished from No. 7 by its lumpy or rolling appearance, and by the fact that it does not tend to rain. (See Plate I. fig. 1.)

7. *Nimbus* (N.). (Raincloud).—A dense layer of dark shapeless cloud, with ragged edges, from which steady rain or snow usually falls. If there are any openings in the cloud an upper layer of cirro-stratus or alto-stratus may almost invariably be seen through them. Nimbus breaking into ragged cloud or into detached fragments underneath a large nimbus (the "Scud" of Sailors) is termed *Fracto-Nimbus* (Fr. Nb.). (See Plate I. fig. 2.)

¹*Manual of Meteorology* (1926), vol. i., chap. xi.

8. *Cumulus* (Cu.) (Woolpack or Cauliflower Cloud).—Thick cloud of which the upper surface is dome-shaped and exhibits protuberances while the base is generally horizontal. (See Plate I. fig. 5.)

9. *Cumulo-nimbus* (Cu. N.) (The Thunder-cloud; shower-cloud).—Great masses of cloud rising in the form of mountains or towers or anvils, generally having a veil or screen of fibrous texture (false cirrus) at the top and at its base a cloud-mass similar to nimbus. From the base local showers of rain or of snow, occasionally of hail or soft hail usually fall. (See Plate I. fig. 3.) The front of a thunderstorm of wide extent is frequently in the form of a large arch above a region of uniformly lighter sky.

10. *Stratus* (S.).—A uniform layer of cloud, like fog, but not lying on the ground.

The international scheme also provides that where certain clouds take a lumpy form, the adjective *cumuliformis* shall be used, and if the base shows downward projecting bosses the word *mammato* shall be prefixed, while for clouds whose shapes approximate to that of a doubly convex lens the term *lenticularis* shall be affixed. In consequence of such modifications as these twelve other cloud forms are added to the ten principal types. Issued as it has been with the authority of an international congress this scheme has been generally accepted, and for the great majority of observations is quite detailed enough, but some specialists considered that for the minuter study of cloud forms a more elaborate scheme was needed. In 1896 H. H. Clayton of the Blue Hill Observatory, Massachusetts, published a highly detailed scheme in which the international types and a number of subdivisions were grouped under four classes—*stratiforms* or sheet clouds; *cumuliforms* or woolpack clouds; *flociforms*, including strato-cumulus, alto-cumulus and cirro-cumulus; and *cirrifirms* or hairy clouds. In 1904 F. L. Obenbach (Cleveland Observatory) devised a system, in which the International types are sub-divided into a number of species, but in the absence of any definitive atlas neither of these American schemes has come into general use.

In general, during the 20th century the tendency of independent workers has been to increase the number of forms, sometimes to an unwieldy number. The cirrus type exhibits so many diverse forms that it has been found specially prolific in sub-types, e.g., Clayton in *Cloud Studies* (1905 and 1925) names nine varieties. Vincent in *Atlas des Nuages* (Brussels, 1909) gives 13 varieties, as also does Besson in *Aperçu historique sur la classification des Nuages* (1923). Improvements in photographic methods both from the ground and by aviators from above the cloud layers has considerably stimulated interest in the subject and in this connection Clayton's *Cloud Studies* is notable. Not only does it contain beautiful photographs but much information is given on camera technique. For photographs of "clouds as seen from an aeroplane" reference should be made to Douglas's article with this title in the *Q. J. R. Met. Soc.* (1920, pp. 233–242), while for an extended bibliography on the subject, which is now becoming a formidable list, see *Manual of Meteorology*, vol. i., by Shaw and Austen (1926).

CLOUDBERRY, *Rubus Chamaemorus*, a low-growing creeping herbaceous plant (family, Rosaceae) with simple obtusely lobed leaves and solitary white flowers, resembling those of the blackberry, but larger—one inch across—and with stamens and pistils on different plants. The orange-yellow fruit is about half an inch long and consists of a few large drupes with a pleasant flavour. The plant occurs in the mountainous parts of Great Britain, and is widely distributed through the more northerly portions of both hemispheres. In North America it grows in peat bogs and on mountains from Maine and New Hampshire to Arctic America and westward to Alaska and British Columbia. In Denmark and Sweden the fruit is gathered in large quantities and sold in the markets.

CLOUD-BURST, a term popularly applied to an excessively heavy fall of rain, usually of brief duration, over a small area of the earth's surface. Most so-called cloud-bursts occur in connection with thunder-storms. In these storms there are violent uprushes of air, which at times prevent the condensing raindrops from falling to the ground. A large amount of water may thus

BY COURTESY OF THE UNITED STATES WEATHER BUREAU

CLOUD FORMS

1. Alto-stratus, above a layer of fog or stratus, a dense sheet of grey or bluish colour, forming sometimes a very compact and at other times a thin mass of dull grey colour and fibrous structure
2. Nimbus raincloud with fog or stratus below, a dense layer of shapeless cloud, with ragged edges, from which steady rain or snow usually falls
3. Cumulo-nimbus (thunder- or shower-cloud), just grown from cumulus. Great masses of cloud rising in the form of mountains or towers or anvils, generally having a veil or screen of fibrous texture (false cirrus) at the top and at its base a cloud-like mass similar to nimbus. From the base local showers of rain or snow usually fall
4. Tufted cirrus, detached clouds of delicate appearance, of fibrous or thread-like structure and feather-like form, generally white in colour
5. Cumulus (wool-pack or cauliflower cloud), thick cloud of which the upper surface is dome-shaped and exhibits protuberances, while the base is generally horizontal
6. Cumulus, with strato-cumulus below, thin alto-stratus above. Below strato-cumulus, appearing as lumpy rolls of dull grey cloud, such as may frequently cover the whole sky, especially in winter. Alto-stratus appears above as a dense sheet of grey or bluish colour and fibrous texture

BY COURTESY OF THE UNITED STATES WEATHER BUREAU

CLOUD FORMS

1. Strato-cumulus. Large lumpy masses or rolls of dull grey cloud, frequently covering the whole sky, especially in winter. It may be distinguished from a nimbus by its lumpy or rolling appearance and by the fact that it does not tend to rain
2. Cumulo-nimbus. This is a thunder-cloud, with a well-defined anvil top
3. Cirro-cumulus. A mackerel sky with small rounded masses or white flakes without shadows, arranged in groups and often in lines
4. Alto-cumulus. Large rounded masses, white or greyish, partially shaded, arranged in groups or lines, and often so crowded together in the middle region that cloudlets join
5. Mammato alto-stratus. A dense sheet of grey or bluish colour forming a fibrous mass which may be either thin or very compact. The term mammato denotes a cloud of downward-projecting bosses
6. Lenticular alto-stratus. An example of a cloud in the shape of a double convex lens (lenticularis). Dense grey or bluish in colour, compact and of fibrous texture
7. Undulated alto-cumulus. Large rounded masses of white or greyish cloud, partially shaded, arranged usually in groups or lines
8. Strato-cumulus rolls. Large lumpy rolls which frequently cover the sky, particularly in winter. Although in appearance somewhat similar to a nimbus, it is not a rain cloud
9. Dense, bunched cirrus. Generally white in colour, detached clouds of delicate appearance, of fibrous structure and feather-like form
10. Cirro-cumulus. A variation on the cirro-cumulus formation of Fig. 3. A mackerel sky with small rounded masses or white flakes without shadows, arranged in groups and often in lines

accumulate at high levels, and if, for any reason, the upward currents are weakened the whole of this water falls at one time. Cloud-bursts are especially common in mountainous districts. This is probably because the rising air currents of a thunderstorm are more or less broken up by the passage of the storm over a mountain. Of course, the effects of heavy rain are especially striking on mountain slopes because the falling water is concentrated in valleys and gulleys. Mountain cloud-bursts cause very sudden and destructive floods. The intensity of rainfall in the most severe cloud-bursts can only be conjectured. A rainfall of 2.47 in. in 3 min. was registered by an automatic rain-gauge at Porto Bello, Panama, on Nov. 29, 1911, and one of 1.02 in. in 1 min. by two automatic gauges, placed side by side, at Opid's camp, on the west front of the San Gabriel Range, Calif., on April 5, 1926. There have been many cases, however, in which the deep excavations made in the ground by the falling water of a cloud-burst appear to indicate a much greater intensity of rainfall than in the cases above noted.

CLOUET, FRANÇOIS (d. 1572), French miniature painter. The earliest reference to him is the document dated Dec., 1541 (see **CLOUET, JEAN**), in which the king renounces for the benefit of the artist his father's estate which had escheated to the Crown as the estate of a foreigner. In it the younger Janet is said to have "followed his father very closely in the science of his art." Like his father, he held the office of groom of the chamber and painter in ordinary to the king, and so far as salary is concerned, he started where his father left off. A long list of drawings contains those which are attributed to this artist, but we still lack perfect certainty about his works. There is, however, more to go upon than there was in the case of his father, as the praises of François Clouet were sung by the writers of the day, his name was carefully preserved from reign to reign, and there is an ancient and unbroken tradition in the attribution of many of his pictures. There are not, however, any original attestations of his works, nor are any documents known which would guarantee the ascriptions usually accepted. To him are attributed the portraits of Francis I. at the Uffizi, Florence, and at the Louvre, and various drawings relating to them. He probably also painted the portrait of Catherine de' Medici at Versailles and other works, and in all probability a large number of the drawings ascribed to him were from his hand. One of his most remarkable portraits is that of Mary, queen of Scots, a drawing in chalks in the Bibliothèque Nationale, Paris, and of similar character are the two portraits of Charles IX. and the one at Chantilly of Marguerite of France. Perhaps his masterpiece is the portrait of Elizabeth of Austria in the Louvre.

He resided in Paris in the rue de Ste. Avoye in the Temple quarter, close to the Hôtel de Guise, and in 1568 is known to have been under the patronage of Claude Gouffier de Boisy, Seigneur d'Oiron, and his wife Claude de Baune. Another ascertained fact concerning François Clouet is that in 1571 he was "summoned to the office of the Court of the Mint," and his opinion was taken on the likeness to the king of a portrait struck by the mint. He prepared the death-mask of Henry II., as in 1547 he had taken a similar mask of the face and hands of Francis I., in order that the effigy to be used at the funeral might be prepared from his drawings; and on each of these occasions he executed the painting to be used in the decorations of the church and the banners for the great ceremony.

Several miniatures are believed to be his work, one very remarkable portrait being the half-length figure of Henry II. in the collection of the late J. Pierpont Morgan. Another of his portraits is that of the duc d'Alençon in the Jones collection at South Kensington, and certain representations of members of the royal family which were in the Hamilton Palace collection and the Magniac sale are usually ascribed to him. He died on Dec. 22, 1572, shortly after the massacre of St. Bartholomew, and his will, mentioning his sister and his two illegitimate daughters, and dealing with the disposition of a considerable amount of property, is still in existence. His daughters subsequently became nuns. Like his father, he was known as JANET.

His work is remarkable for the extreme accuracy of the draw-

ing, the elaborate finish of all the details, and the exquisite completeness of the whole portrait. He must have been a man of high intelligence, and of great penetration, intensely interested in his work, and with considerable ability to represent the character of his sitter in his portraits. His colouring is perhaps not specially remarkable, nor from the point of style can his pictures be considered specially beautiful, but in perfection of drawing he has hardly any equal.

See Louis Dimier, *French Painting in the Sixteenth Century*; also works of MM. Bouchot, La Borde, Maulde-La Clavière and E. Moreau-Nelaton, *Les Clouets et leurs émules* (1921). (G. C. W.)

CLOUET, JEAN (d. c. 1541), French miniature painter, generally known as JANET. The authentic presence of this artist at the French court is first to be noted in 1516, the second year of the reign of Francis I. By a deed of gift made by the king to the artist's son of his father's estate, which had escheated to the Crown, we learn that he was not actually a Frenchman, and never even naturalized. He is supposed to have been a native of the Low Countries, and probably his real name was Clowet. His position was that of groom of the chamber to the king, and he received a stipend at first of 180 livres and later of 240. He lived several years in Tours, and there it was he met his wife, who was the daughter of a jeweller. He is recorded as living in Tours in 1522, and there is a reference to his wife's residence in the same town in 1523, but in 1529 they were both settled in Paris, probably in the neighbourhood of the parish of St. Innocent, in the cemetery of which they were buried. He stood godfather at a christening on July 8, 1540, but was no longer living in Dec. 1541, and therefore died between those two dates.

His brother, known as **CLOUET DE NAVARRE**, was in the service of Marguerite d'Angoulême, sister of Francis I., and is referred to in a letter written by Marguerite about 1529. Jean Clouet had two children, François, and Catherine, who married Abel Foulon, and left one son, who continued the profession of François Clouet after his decease. Jean Clouet was undoubtedly a very skilful portrait painter, but it must be acknowledged without hesitation that there is no work in existence which has been proved to be his. There is no doubt that he painted a portrait of the mathematician, Oronce Finé, in 1530, when Finé was 36 years old, but the portrait is now known only by a print. Janet is generally believed, however, to have been responsible for a very large number of the wonderful portrait drawings now preserved at Chantilly, and at the Bibliothèque Nationale, Paris, and to him is attributed the portrait of an unknown man at Hampton Court, that of the dauphin Francis, son of Francis I. at Antwerp, and one other portrait, that of Francis I. in the Louvre.

Seven miniature portraits in the *Manuscript of the Gallic War* in the Bibliothèque Nationale (13,429) are attributed to Janet with very strong probability, and to these may be added an eighth in the collection of the late J. Pierpont Morgan, and representing Charles de Cossé, Maréchal de Brissac, identical in its characteristics with the seven already known. There are other miniatures in the Morgan collection, which may be attributed to Jean Clouet with some strong degree of probability, inasmuch as they closely resemble the portrait drawings at Chantilly and in Paris which are taken to be his work. In his oil paintings the execution is delicate and smooth, the outlines hard, the texture pure, and the whole work elaborately and very highly finished in rich, limpid colour. The chalk drawings are of remarkable excellence, the medium being used by the artist with perfect ease and absolute sureness, and the mingling of colour being in exquisite taste, the modelling exceedingly subtle, and the drawing careful, tender and emphatic. The collection of drawings preserved in France, and attributed to this artist and his school, comprises portraits of all the important persons of the time of Francis I. In one album of drawings the portraits are annotated by the king himself, and his merry reflections, stinging taunts or biting satires, add very largely to a proper understanding of the life of his time and court. Definite evidence, however, is still lacking to establish the attribution of the best of these drawings and of certain oil paintings to the Jean Clouet who was groom of the chambers to the king.

The chief authority in France on the work of this artist is Louis Dimier. See also E. Moreau-Nelaton, *Les Clouets et leurs émules* (1921). (G. C. W.)

CLOUGH, ANNE JEMIMA (klūf) (1820–1892), educationalist and sister of the poet, Arthur Hugh Clough, born at Liverpool Jan. 20, 1820. When two years old she went with her family to Charleston, U.S.A., but returned to England in 1836. Her father's failure in business led her to open a school in 1841 which was carried on until 1846. In 1852, after studying in London and working at the Borough road and the Home and Colonial schools, she opened another school at Ambleside, in Westmorland. Keenly interested in the education of women, she made friends with Miss Emily Davies, Madame Bodichon, Miss Buss and others. After helping to found the North of England council for promoting the higher education of women, she acted as its secretary from 1867–70 and as president from 1873–74. When it was decided to open a house for women students at Cambridge, Miss Clough was chosen as its first principal. This hostel, started in Regent street, Cambridge, in 1871 with five students, and continued at Merton hall in 1872, led to the building of Newnham hall, opened in 1875, and to the erection of the present Newnham college, Cambridge, in 1880. Miss Clough's personal charm and high aims, together with her work at Newnham college, made her one of the leaders of the women's educational movement. She died on Feb. 27, 1892.

See B. A. Clough, *Memoir of Anne Jemima Clough* (1903).

CLOUGH, ARTHUR HUGH (1819–1861), English poet, was born at Liverpool on Jan. 1, 1819. In 1822 his father, a cotton merchant, moved to the United States, and Clough's childhood was spent mainly at Charleston (S.C.). In 1828 the family visited England, and Clough was left at school at Chester, whence he passed in 1829 to Rugby, then under Dr. Thomas Arnold. In 1837 he went with a scholarship to Balliol college, Oxford. Here his contemporaries included Benjamin Jowett, A. P. Stanley, J. C. Shairp, W. G. Ward, Frederick Temple and Matthew Arnold. Clough missed a Balliol fellowship, but obtained one at Oriel, with a tutorship, and lived the Oxford life of study, speculation, lectures and reading-parties until 1848, when he went abroad, seeing Paris in revolution and Rome in siege. In the autumn of 1849 he became principal of University Hall, a hostel for students at University college, London. He disliked London, in spite of the friendship of the Carlyles, nor did the atmosphere of Unitarianism prove any more congenial than that of Anglican Oxford to his critical and at bottom conservative temper. In 1852 encouraged by Emerson, he went to Cambridge (Mass.). Here he remained some months, lecturing and translating Plutarch for the booksellers, until in 1853 the offer of an examinership in the Education Office brought him to London once more. He married, and pursued a steady official career, diversified only by an appointment in 1856 as secretary to a commission sent to study certain aspects of foreign military education. In 1860 his health began to fail. He visited first Malvern and Freshwater, and then the East, France and Switzerland, in search of recovery, and finally came to Florence, where he died on Nov. 13, 1861. Matthew Arnold wrote upon him the exquisite lament of *Thyrsis*.

Shortly before he left Oxford, in the stress of the Irish potato-famine, Clough wrote an ethical pamphlet addressed to the undergraduates, with the title, *A Consideration of Objections against the Retrenchment Association at Oxford* (1847). His Homeric pastoral *The Bothie of Tober-na-Fuossich*, afterwards rechristened *Tober-na-Vuolich* (1848), was inspired by a long vacation reading-party after he had given up his tutorship, and is an entertaining experiment. *Ambarvalia* (1849), published jointly with his friend Thomas Burbidge, contains shorter poems of various dates from 1840, or earlier, onwards. *Amours de Voyage*, a novel in verse, was written at Rome in 1849; *Dipsychus*, a rather amorphous satire, at Venice in 1850; and the idylls which make up *Mari Magno or Tales on Board*, in 1861. A few lyric and elegiac pieces, later in date than the *Ambarvalia* complete the tale of Clough's poetry. His only considerable enterprise in prose was a revision of the 17th century translation of Plutarch by Dryden and others, which occupied him from 1852, and was

published as *Plutarch's Lives* (1859).

He is rightly regarded, like his friend Matthew Arnold, as one of the most typical English poets of the middle of the 19th century. His critical instincts and strong ethical temper brought him athwart the popular ideals of his day both in conduct and religion. His verse has upon it the melancholy and the perplexity of an age of transition. He is a sceptic who by nature should have been with the believers. He stands between two worlds, watching one crumble behind him, and only able to look forward by the sternest exercise of faith to the reconstruction that lies ahead in the other. On the technical side, Clough's work is interesting to students of metre, owing to the experiments which he made, in the *Bothie* and elsewhere, with English hexameters.

BIBLIOGRAPHY.—Clough's *Poems* were privately collected, with a short memoir by F. T. Palgrave, in 1862; and his *Poems and Prose Remains* with a memoir by his widow in 1869. Selections from the poems were made by Mrs. Clough for the Golden Treasury series in 1894, and by E. Rhys in 1896. See monographs by S. Waddington (1883) and J. L. Osborne (1920). Clough's sister Anne Jemima Clough (1820–92) was the first principal of Newnham college, Cambridge.

CLOVELLY, a fishing village of Barnstaple bay, Devonshire, England, 11 m. W.S.W. of Bideford. Pop. (1921) 634. It is a cluster of old-fashioned cottages in a unique position on the sides of a rocky cleft in the north coast; its main street resembles a staircase, which descends 400 ft. to the pier, too steeply to allow of any wheeled traffic. All Saints' church, restored in 1866, is late Norman. The climate is very mild. Thick woods shelter the village on three sides and the surrounding scenery is famous for its richness of colour. Clovelly is described by Dickens in *A Message from the Sea*.

CLOVEN-HOOFED ANIMALS, the popular designation for members of the order Artiodactyla (*q.v.*), which includes the sheep, cattle, deer, antelopes, goats and swine (*qq.v.*).

CLOVER, the English name for plants belonging to the genus *Trifolium*, so-called from the leaf, which has three leaflets (trifoliate). It is a member of the family *Leguminosae*, and contains about 300 species, found chiefly in north temperate regions, but also, like other north temperate genera on the mountains in the tropics. The plants are small annual or perennial herbs with trifoliate (rarely 5- or 7-foliate) leaves with stipules adnate to the leaf-stalk, and heads or dense spikes of small red, purple, white or rarely yellow flowers; the small few-seeded pods are enclosed in the calyx. Twenty species are native in Britain, and several are extensively cultivated as fodder-plants. *T. pratense*, red or purple clover, of which there are a number of varieties, is the most widely cultivated. *T. incarnatum*, crimson or Italian clover, though rather tender, is a most valuable forage crop in the warmer parts of England. *T. repens*, white or Dutch clover, is a perennial abundant in meadows and good pastures. The flowers are white or pinkish, becoming brown and deflexed as the corolla fades. There are a number of commercial varieties, e.g., wild white, cultivated white and mammoth. *T. hybridum*, alsike or Swedish clover is a perennial which was introduced from Sweden in 1834 and has now become naturalized in Britain. The flowers are pale pink or white and resemble those of the last species. *T. medium*, zig-zag clover, a perennial with straggling flexuous stems and rose-purple flowers, is not met with in commerce. *T. minus*, common in pastures and roadsides, with smaller heads and small yellow flowers, turning dark brown, is the shamrock. Nearly all the foregoing have become very widely naturalized in the United States and Canada. Specimens of shamrock and other clovers are not infrequently found with four leaflets and, like other rarities, are considered lucky.

Cultivation.—Clover was originally introduced from Flanders into England as a farm crop about the middle of the 17th century by Sir Richard Weston. He is distinguished in the annals of agriculture as being the first to introduce into England the rotation of crops based on roots and clover, although it was not until a century later that the new system was adopted on any wide scale. Clover is grown as a farm crop in all parts of Great Britain and occupies about one-fourth of the total arable area. It is frequently sown with rye-grass or other green crops and appears

in the agricultural returns under the heading of "clover and rotation grasses."

There are several kinds of clover in common agricultural use, including white, or Dutch clover, red or broad clover, alsike and *Trifolium incarnatum*. White clover is indigenous and is found in most good pastures, especially on rich land containing lime. It has a creeping habit—hence its botanical name *Trifolium repens*—and is usually eaten off by sheep, as it is not profitable to mow it. In recent years "wild white clover" has come into much favour. Broad or red clover is known also as purple clover and is probably more widely grown than any other kind. It is commonly cut for hay but, like the white clover, is also folded with sheep. It will stand for two or three years, or even more, but is specially susceptible to "clover sickness," a disease caused by minute organisms in the stem of the plant. When land becomes "clover sick" it usually requires some years to recover before it can successfully grow the crop again. *Trifolium*, although a name properly applicable to all kinds of clover, has been appropriated by farmers to that handsome and easily recognizable kind which bears large dark crimson flowers (*T. incarnatum*). This is often taken as a catch crop, sown on the stubbles and fed off in May or June. Cow grass is a variety of red clover which, although somewhat slower in growth, is more lasting and is less liable to clover-sickness. It is well adapted for a mixture of "seeds" intended to remain down for some time.

In the strict four-course rotation clover, or "seeds," stand only for one year, but it has long been the practice with many farmers to leave the crop for two or more years, or by sowing with suitable mixtures to let it remain for several years as a temporary pasture. (See GRASS AND GRASSLAND.) (X.)

UNITED STATES.

The economically valuable clovers in America are all traceable to European origin. No native species has been cultivated. The cultivated clovers are red (*Trifolium pratense*), alsike (*T. hybridum*), crimson (*T. incarnatum*), and white (*T. repens*). Besides these, subterranean clover (*T. subterraneum*) and strawberry clover (*T. fragiferum*) have been introduced to a limited extent from Australia, where they assume considerable importance as grazing plants.

Clover Culture.—Red and alsike clover occupy practically the same place in American agriculture and are treated together in crop statistics. The chief clover region in America is the area from the western border of Minnesota, Iowa and Missouri and the southern border of Missouri, Tennessee and North Carolina, east and north into Canada. Red and alsike clovers are commonly seeded with timothy, sometimes alone. In the north-eastern quarter of the United States more than 52% of the hay acreage contains clover and it is therefore the most important legume in this part of the United States. Seeding of red and alsike clover is commonly done with a "nurse" crop of small grain and no harvest is taken during the seeding year. The next year the first crop is cut for hay and the second may be cut for hay, or for seed, or it may be turned under for soil improvement.

Clover Failure.—What is called clover sickness in Great Britain, does not occur in the United States except to a limited extent in western Oregon, although the disease is occasionally serious on crimson clover on the Atlantic sea board. The failure of clover to make a stand or to give a satisfactory yield is, however, not uncommon. The causes are lack of lime, phosphorous or potash and lack of organic matter. These deficiencies are in most cases due to poor farming methods, such as prolonged cultivation without adequate rotations. Another common cause of failure is the use of the seed of non-adapted strains.

Varieties and Strains.—There are in use in America two varieties, the early or June red and the mammoth. These are respectively comparable to, but not the same as, the English double-cut and single-cut clovers. The American clover has spreading hairs, while the European clovers are smooth or have appressed hairs. For conditions in the United States, no imported clovers are so well adapted as the American type. Some European clovers, as the Italian, are quite unsuited to American conditions, while

French and Russian may be used in some sections but not in others. French clover is not cold-resistant enough for regions with severe winters and all European clovers are more susceptible to disease and to insect injury in the United States than the American clover. An exception occurs in the case of clover mildew, to which the American clover is more susceptible than the European. One of the chief factors in clover failure during recent years has been the large importations of seed of European strains. Such importations have averaged about 12,000,000 lb. per year. (For further information on clover failure the reader is referred to publications of the U.S. Department of Agriculture and State agricultural experiment stations.)

Other Clovers.—White clover is used as a pasture plant everywhere save in the semi-arid regions. It is seldom seeded but comes up naturally. The mammoth white clover of England is called Ladino in America and is successful in the irrigated regions of the West. The wild white, so highly regarded in Britain, is of no special value in the United States. Crimson clover is used mainly on the Atlantic seaboard from New Jersey south as a soil improving crop.

The hop clovers have been introduced from Europe and one of them, the least hop clover, the true shamrock, has become of some importance as a pasture plant in Louisiana and Arkansas. Other so-called clovers are sweet clover and Japan clover or Lespedeza, a valuable pasture plant throughout the South which was introduced from Japan some time before 1856, and has spread naturally from southern Indiana to the gulf and as far west as eastern Kansas.

Seed Production.—Red clover seed is produced over most of the main clover area and in the irrigated region of the West. It is commonly taken from the second crop. Alsike clover seed is produced in the same region as red, but is taken from the first crop, since this species does not commonly produce two cuttings in a season. White clover seed is produced chiefly in Wisconsin and Louisiana, although small amounts are harvested elsewhere. Crimson clover seed for the trade is produced in small amounts in Delaware, Maryland and Tennessee, but is frequently harvested for home use in other sections.

Native Clovers.—There are upwards of 50 native species of clover on the Pacific coast (35 occurring in California) and in the Rocky mountain region, but east of the Mississippi river only four native species occur. See GRASS AND GRASSLAND.

(A. J. PL.)

CLOVES, the dried, unexpanded flower-buds of *Eugenia aromatica*, a tree belonging to the family Myrtaceae. The clove tree is a beautiful evergreen which grows to a height of 40 ft., having large oval leaves and crimson flowers in numerous groups of terminal clusters. The flower-buds are at first of a pale colour and gradually become green, after which they develop into a bright red, when they are ready for collecting. Cloves are rather more than half an inch in length, and consist of a long cylindrical calyx, terminating in four spreading sepals, and four unopened petals which form a small ball in the centre. The tree is a native of the Moluccas, or Spice islands; but it was long cultivated by the Dutch in Amboyna and two or three small neighbouring islands. Cloves were one of the principal Oriental spices that early excited the cupidity of Western commercial communities, having been the basis of a rich and lucrative trade from an early part of the Christian era. The Portuguese, by doubling the Cape of Good Hope, obtained possession of the principal portion of the clove trade, which they continued to hold for nearly a century when, in 1605, they were expelled from the Moluccas by the Dutch. Holland exerted great and inhuman efforts to obtain a complete monopoly of the trade, attempting to extirpate all the clove trees growing in their native islands, and to concentrate the whole production in the Amboyna islands. With great difficulty the French succeeded in introducing the clove tree into Mauritius in the year 1770; subsequently the cultivation was introduced into Guiana, Brazil, most of the West Indian islands, and Zanzibar. The chief commercial sources of supply were for a long time Zanzibar and its neighbouring island Pemba on the East African coast, but the competition of Java and Sumatra is now severe and

the synthetic production of eugenol (*see* below) has affected the trade.

Cloves as they come into the market have a deep brown colour, a powerfully fragrant odour, and a hot acrid taste. When pressed they exude a volatile oil which is obtained as a commercial product by submitting the cloves with water to repeated distillation. This is, when new, a pale yellow or almost colourless fluid, becom-

FROM KÖHLER, "MEDIZINALE PFLANZEN"

BRANCH OF A CLOVE TREE SHOWING THE FLOWER BUDS WHICH, WHEN DRIED, MAKE THE CLOVES OF COMMERCE

ing brown after some time; it possesses the odour and taste peculiar to cloves. The essential oil of cloves—the *Oleum Caryophylli* of the British Pharmacopoeia—is a mixture of two substances. *Eugenol* or eugenic acid, $C_{10}H_{12}O_2$, is the chief constituent. Oil of cloves is soluble in alcohol and ether. Cloves are employed as a condiment in culinary operations, in confectionery, and in the preparation of *liqueurs*. In medicine they are tonic and carminative but they are little used except as adjuncts to other substances. The oil forms a convenient medium for using cloves for flavouring purposes, possesses the medicinal properties characteristic of a volatile oil, and is frequently employed to relieve toothache. Oil of cloves is regarded by many dental surgeons as the most effective local anaesthetic they possess.

CLOVIO, GIORGIO GIULIO (1498–1578), Italian painter of portraits and historical pieces, by birth a Croat and by profession a priest, is said to have studied at Rome under Giulio Romano, and at Verona under Girolamo de' Libri. His book of 26 pictures representing the procession of Corpus Domini, in Rome, was the work of nine years, and the covers were executed by Benvenuto Cellini. The British Museum has his twelve miniatures of the victories of the Emperor Charles V. In the Vatican library is preserved a manuscript life of Frederick, duke of Urbino, superbly illustrated by Clovio, who is *facile princeps* among Italian miniaturists. He was called Macedo, or Macedone, to connect him with his supposed Macedonian ancestry.

CLOVIS (*Chlodovech*) (c. 466–511), king of the Salian Franks, son of Childeric I., whom he succeeded in 481 at the age of 15. At that date the Salian Franks had advanced as far as the river Somme, and the centre of their power was at Tournai. On the history of Clovis between the years 481 and 486 the records are silent. In 486 he attacked Syagrius, a Roman general who, after the fall of the western empire in 476, had carved out for himself a principality south of the Somme, and is called by Gregory of Tours "rex Romanorum." After being defeated by Clovis at the battle of Soissons, Syagrius sought refuge with the Visigothic king Alaric II., who handed him over to the conqueror.

Henceforth Clovis fixed his residence at Soissons, which was in the midst of public lands, e.g., Berny-Rivière, Juvigny, etc. The episode of the vase of Soissons¹ has a legendary character, and all that it proves is the deference shown by the pagan king to the orthodox clergy. Clovis undoubtedly extended his dominion over the whole of Belgica Secunda, of which Reims was the capital, and conquered the neighbouring cities in detail. Little is known of the history of these conquests. It appears that St. Genevieve defended the town of Paris against Clovis for a long period, and that Verdun-sur-Meuse, after a brave stand, accepted an honourable capitulation thanks to St. Euspitius. In 491 some barbarian troops in the service of Rome, Arboruchi ('*Ἀρμπορυχοί*) Thuringians, and even Roman soldiers who could not return to Rome, went over to Clovis and swelled the ranks of his army.

In 493 Clovis married a Burgundian princess, Clotilda, niece of Gundobald and Godegisil, joint kings of Burgundy. This princess was a Christian, and earnestly desired the conversion of her husband. Although Clovis allowed his children to be baptized, he remained a pagan himself until the war against the Alamanni, who at the time occupied the country between the Vosges, and the Rhine and the neighbourhood of Lake Constance. By pushing their incursions westward they came into collision with Clovis, who marched against them and defeated them in the plain of the Rhine. The legend runs that, in the thickest of the fight, Clovis swore that he would be converted to the God of Clotilda if her God would grant him the victory. After subduing a part of the Alamanni, Clovis went to Reims, where he was baptized by St. Remigius on Christmas day 496, together with 3,000 Franks. The story of the phial of holy oil (the *Sainte Ampoule*) brought from heaven by a white dove for the baptism of Clovis was invented by archbishop Hincmar of Reims three centuries after the event.

The baptism of Clovis was an event of very great importance. From that time the orthodox Christians in the kingdom of the Burgundians and Visigoths looked to Clovis to deliver them from their Arian kings. Clovis seems to have failed in the case of Burgundy, which was at that time torn by the rivalry between Godegisil and his brother Gundobald. Godegisil appealed for help to Clovis, who defeated Gundobald on the banks of the Ouche near Dijon, and advanced as far as Avignon (500), but had to retire without being able to retain any of his conquests. Immediately after his departure Gundobald slew Godegisil at Vienne, and seized the whole of the Burgundian kingdom. Clovis was more fortunate in his war against the Visigoths. Having completed the subjugation of the Alamanni in 506, he marched against the Visigothic king Alaric II. in the following year, in spite of the efforts of Theodoric, king of the Ostrogoths, to prevent the war. After a decisive victory at Vouillé near Poitiers, in which Clovis slew Alaric with his own hand, the whole of the kingdom of the Visigoths as far as the Pyrenees was added to the Frankish empire, with the exception of Septimania, which, together with Spain, remained in possession of Alaric's grandson Amalaric, and Provence, which was seized by Theodoric and annexed to Italy. In 508 Clovis received at Tours the insignia of the consulship from the eastern emperor, Anastasius, but the title was purely honorific. The last years of his life Clovis spent in Paris, which he made the capital of his kingdom; here he built the church of the Holy Apostles, known later as the church of St. Geneviève. By murdering the petty Frankish kings who reigned at Cambrai, Cologne and other residences, he became sole king of all the Frankish tribes. He died in 511.

Clovis was the true founder of the Frankish monarchy. He reigned over the Salian Franks by hereditary right; over the other Frankish tribes by reason of his kinship with their kings and by the choice of the warriors, who raised him on the shield, and he governed the Gallo-Romans by right of conquest. He had the

¹The story is as follows. The vase had been taken from a church by a Frankish soldier after the battle of Soissons, and the bishop had requested Clovis that it might be restored. But the soldier who had taken it refused to give it up, and broke it into fragments with his *francisca*, or battle-axe. Some time afterwards, when Clovis was reviewing his troops, he singled out the soldier who had broken the vase, upbraided him for the neglect of his arms, and dashed his *francisca* to the ground. As the man stooped to pick it up, the king clove his skull with the words "Thus didst thou serve the vase of Soissons."

alic law drawn up, doubtless between the years 486 and 507, and seems to have been represented in the cities by a new functionary, the *graf*, comes, or count. He owed his success in great measure to his alliance with the church. He took the property of the church under his protection, and in 511 convoked a council at Orleans, the canons of which have come down to us. But while protecting the church, he maintained his authority over it. He intervened in the nomination of bishops, and at the council of Orleans it was decided that no one, save a son of a priest, could be ordained clerk without the king's order or the permission of the count.

The chief source for the life of Clovis is the *Historia Francorum* (bk. ii.) of Gregory of Tours, but it must be used with caution. Among modern works, see W. Junghans, *Die Geschichte der fränkischen Könige Childerich und Clodovech* (1857); F. Dahn, *Urgeschichte der germanischen und romanischen Völker*, vol. iii. (1883); W. Schultze, *Deutsche Geschichte v.d. Urzeit bis zu den Karolingern*, vol. ii. (1896); G. Kurth, *Clovis* (1901). (C. Pf.)

CLOVIS, a city of New Mexico, U.S.A., near the centre of the eastern boundary of the State; the county seat of Curry county. It is on Federal highways 70 and 366, and is served by the Santa Fe railroad. The population was 4,904 in 1920, and was 8,027 in 1930 by the Federal census. It has grain elevators, railroad shops and a flour-mill, and ships large quantities of wheat, fruits, kafir corn, cattle and hogs. Clovis was settled about 1907; incorporated in 1908; and in 1921 adopted a commissioner-manager form of government.

CLOWES, SIR WILLIAM LAIRD (1856–1905), British author and journalist, was born at Hampstead, London, on Feb. 1, 1856, the son of William Clowes, a former registrar in chancery, and died at St. Leonards-on-Sea on Aug. 14, 1905. He was entered at Lincoln's Inn in 1877, but was never called, and began journalism in 1879, devoting himself especially to the study of naval matters. As special correspondent of the *Daily News* (1885), the *Standard* (1887–90), and the *Times* (1890–95), he was present at naval manoeuvres and had opportunities of close and first-hand studies. His review and newspaper articles, written often under the pen-name "Nauticus," were regarded as authoritative both in England and on the Continent. He founded, and for a time edited, the *Naval Pocket Book*, and with Sir Clements Markham, Captain A. T. Mahan and others, wrote *The Royal Navy; its History from the Earliest Times* (7 vols., 1897–1903).

See a notice by S. E. Fryer in the *Dict. Nat. Biog. (Supplement for 1901–11)*.

CLOWN, a rustic or boorish person; in pantomime, a comic character, always dressed in baggy costume, with face whitened and eccentrically lined with black and red paint. The character probably descends from representations of the devil in mediaeval miracle-plays, developed through the fools or jesters of the Elizabethan drama. The whitened face and baggy costume indicate a connection also with the Pierrot of Italian comedy. The prominence of the clown in pantomime (*q.v.*) is a comparatively modern development as compared with that of Harlequin.

CLOYNE, small market town, Co. Cork, Ireland, 15 m. E.S.E. of the city of Cork. Pop. (1921) 756. An ecclesiastical foundation of the 6th century, it has an ancient oratory and a cathedral (mainly 14th century) dedicated to St. Colman, disciple of St. Finbar of Cork. Opposite the cathedral is a fine round tower 100 ft. high. The town suffered from Scandinavian raids in the 9th century and was laid waste by Dermot O'Brian in 1071 and burned in 1137. In 1430 the bishopric was united to that of Cork, in 1638 it became independent, and in 1660 it was again united to Cork and Ross. It became independent once more in 1678 and so continued until its reunion with Cork in 1835. The name *Cluain-Uamha* signifies "the meadow of the cave," from the limestone caves of the vicinity. The Pipe Roll of Cloyne compiled by Bishop Swaffham in 1364 is a valuable record of mediaeval land tenure. It is now in the Record Office, Dublin, and was edited by Caulfield in 1859. The cathedral contains a memorial to Bishop Berkeley, the philosopher (1685–1753). The town gives its name also to a Roman Catholic diocese with a cathedral at Cobh.

CLUB-FOOT (*talipes*), the name given to deformities of the foot, some of which are congenital, others acquired—the latter being chiefly due to infantile paralysis. *Talipes equinus* is that form in which the heel does not touch the ground, the child resting on the toes. In *talipes varus* the foot is turned inwards and shortened, the inner edge of the foot is raised, and the child walks on the outer edge. These two conditions are often combined, the heel being drawn up and the foot twisted inward; the name given to the twofold deformity is *talipes equino-varus*. It is the most usual congenital form. In *talipes calcaneus* the toes are pointed upwards and the foot rests on the heel. This is always an acquired (paralytic) deformity.

The treatment of congenital club-foot, which is almost invariably *varus* or *equino-varus*, should be begun as soon as the abnormal condition of the foot is recognized. The nurse should be shown how to twist and coax the foot into the improved position, and should so hold it in her hand many times a day. And thus by daily, or, one might almost say, hourly manipulations, much good may be accomplished without distress to the infant. If after weeks or months of these measures insufficient progress has been made, the subcutaneous division of a tendon or two, or of some tendons and ligaments, may be necessary, the foot being subsequently fixed up in the improved position in plaster of Paris. If these subcutaneous operations also prove disappointing, or if, after their apparently successful employment, the foot constantly relapses into the old position, a more radical procedure will be required. Of the many procedures which have been adopted there is, probably, none equal to that of free transverse incision introduced by the late Dr. A. M. Phelps, of New York. By this "open method" the surgeon sees exactly what structures are at fault and in need of division—skin, fasciae, tendons, ligaments; everything, in short, which prevented the easy rectification of the deformity. After the operation, the foot is fixed, without any strain, in an over-corrected position, between plaster of Paris splints.

Talipes valgus is very rare as a congenital defect, but is common as a result of infantile paralysis, and is apt to be combined with the calcanean variety. "Flat-foot" is sometimes called *spurious talipes valgus*; it is due to the bony arches of the foot being called upon to support a weight beyond their power. The giving way of the arches may be due to weakness of the muscles, tendons or ligaments—probably of all three. It is often met with in feeble children, and in nurses, waiters, policemen and others whose duties demand much standing. Exercises on tip-toe, especially with a skipping rope, massage, rest, and tonic treatment will give relief, and shoes or boots may be supplied with the heel and sole thickened along the inner borders to throw the weight on the strong outer border of the foot. When the flat-footed individual stands, it should be upon the outer borders of his feet, or better still, on tip-toe, as this posture strengthens those muscles of the leg which hold up the bony arches.

Morton's Disease.—In some cases of flat-foot severe neuralgia at the root of the toes, comes on after much standing or walking. The pain is due to pressure on the nerves of the toes by the rounded ends of the long bones of the foot near the web of the toes. It does not generally yield to palliative measures; the only effectual remedy is resection of the head of one of the metatarsal bones, after which relief is complete and permanent.

For paralytic club-foot, in which distressing corns have developed over the unnatural prominences upon which the sufferer has been accustomed to walk, conservative measures are usually disappointing, and relief may be obtainable only after a Syme's amputation through the ankle-joint.

CLUB-MOSS, the common name for plants of the genus *Lycopodium*, and often extended to cover all the Lycopodiales, which form one of the main divisions of the Pteridophyta (*q.v.*), a group which also includes the ferns. Club-mosses are also called staghorn-mosses.

CLUBS. Although the club as an institution was known to the Greeks and Romans, to the former as *hetaireia*, to the latter as *sodalitas*, and was, indeed, recognized in nearly all the states of the ancient civilized world, its organization and aims differed essentially from those of modern times. Such centres were, indeed,

associations rather than clubs, as we understand the term, and may be more appropriately likened to the trade guilds of later days, their chief purpose being religious observances, trade organization, and even privateering, as is proved by certain references to them in one of the laws of Solon; while those associated with the pleasures of the table seem to have approximated to the modern *table d'hôte*, where a number of people gathered together for meals in common, probably as much from economical purposes as for anything else. The religious clubs of the Greeks were the most important, and were in effect the parents of all such collocations of men, but had little in common with the club of modern times, although certain contemporary political organizations of the kind do appear to have had more or less affinity to the recognized objects of many later clubs instituted for similar purposes.

Grote (*Hist. of Greece*) and others show, however, that even when connected with politics the clubs of the Greeks were fundamentally unlike the modern conception of the political club; for even if legal and harmless at first they degenerated, owing to party struggles, into actively hostile associations.

The religious clubs of the Greeks were combinations of men drawn together for some specific object, such as the worship of some particular deity of an esoteric character; *i.e.*, one not recognized by the State; and thus approximating to the various sects of our own established religion rather than to clubs as we understand the term. Such cults as those of Isis and Serapis, Attis and the rest, were carried on by associations specially organized for their support—support to which the State had no objection so long as they did not infringe the laws or were not subversive of its moral well-being. That the organization of such sects should be on not very different lines from those of modern clubs, possessing as they did equivalents to our committee, chairman, secretary, etc., is only what obtains in any body of men meeting together for such purposes; but otherwise these Greek clubs had nothing in common with the modern club, as M. Foucort's account of the subject (*Les Associations Religieuses chez les Grecs*, 1873), is sufficient to show.

With the Romans, too, what are described as clubs in those days should more properly be entitled trade guilds, in which the basic idea was the furtherance of the special commercial activity in which the members were interested. The political clubs of Cicero's time had a closer analogy to ours, but even then their activities were of such a very different character that we find them suppressed by Julius Caesar as being dangerous to public order. The Romans had, too, like the Greeks, their religious sects (*sodalitates*), but they bring us no nearer to our conception of a club; and one of the few of these whose objects can be said to have survived in our day is the Burial Club associated with the poorer classes who were much preoccupied with a decent sepulture. As a matter of fact it is probable that the true clubs of ancient Rome were to be found in the baths, where, without committees or secretary or club-houses of their own, the wealthy and important congregated for ease and conversation, as men and women do in existing clubs throughout the world.

Justus Lipsius does, however, mention a Roman club which had an obviously nearer affinity, at least in its rules and regulations, to those of our own day; and which was similar to the *symposia*, referred to by Cicero in his *De Senectute*, which he says he enjoyed less for their gastronomical attractions than for the opportunities they afforded him of talking, which incidentally shows that he was probably the first of the redoubtable army of club-bosers.

When the word "club" first began to take on its present significance is an open question; for, although Carlyle (*Frederick the Great*) indicates that it had its equivalent in the *gelübe* of the chivalric orders in Germany, on the other hand the German *klubbe* is directly borrowed from our own word. In the 17th century *club* is found used, in the connection it now connotes, by Aubrey and Pepys, the former remarking that "we now use the word *clubbe* for a sodality in a tavern," and the latter speaking of a tavern in Pall Mall as the place whither he and his friends resorted "for clubbing."

It was, however, in the 18th century that the club, more or less

on the lines familiar to us, first rose into general prominence and favour, although it had certain forerunners which possessed characteristics common to it in its later development. The earliest of these was *Le Court de Bone Compagnie*, which flourished in the reign of Henry IV., of which the poet Hoccleve, who was a member, has left some poetical data. It was obviously in the nature of what we should now call a dining club, as were certain famous successors in the time of Elizabeth, notably the *Friday Street* or *Bread Street Club*, traditionally supposed to have been founded by Sir Walter Raleigh, but now chiefly remembered from the name of its meeting-place, the Mermaid Tavern. A contemporary club was the *Apollo*, whose members foregathered at the Devil Tavern by Temple Bar, where Ben Jonson, who drew up its rules, dominated the meetings as Dryden was to do at Will's a century later.

With the introduction of coffee-houses, about the middle of the 17th century, clubs found more or less permanent headquarters, and their great development at the beginning of the following century may be directly ascribed to this circumstance, although one of a specialized character, *The Royal Navy Club*, inaugurated in 1674, was the parent of those service clubs which only came into existence during the early years of the 19th century.

Of the few other clubs of Stuart times whose names have survived, *The Rota*, which Pepys calls the Coffee Club, no doubt because it met at Miles' Coffee House, in Westminster, founded by James Harrington in 1659, is the best known. Its principles were republican, whereas those of another somewhat later club, *The Sealed Knot* (1688), were distinctly royalist. *The Civil Club* (1669) may be regarded as the direct forerunner of the City of London Club which did not come into existence till 1832. At the *Wednesday Club*, which met in Friday street, William Paterson directed the conferences which went by its name and ultimately resulted in the establishment of the Bank of England. Such associations as these had no actual home of their own, nor was there any financial obligation on the part of the members beyond the payment of their "scot"; a room being freely allocated for their use by the landlord of a coffee-house, who found generally an adequate return in the food and wine consumed by the members, and where the members were notable men, in the attraction to his premises of the general public through their means.

CLUBS IN THE EIGHTEENTH CENTURY

With the beginning of the 18th century there was a sudden and large increase of clubs in London. Passing over the notorious *Calves' Head Club* (*q.v.*) we may note that a number of clubs arose whose doings are mentioned in *The Tatler* and *The Spectator*, and with some of which the names of Swift and Bolingbroke are closely associated. Of these the *October Club* (1710-11), which gave no little trouble to Harley's administration, and its more advanced offshoot, the *March Primitive October Club*; the *Saturday Club*, inaugurated by Bolingbroke in 1711; the *King's Head*, or *Green Ribbon Club*, due to Shaftesbury's efforts; and the *Hanover Club*, organized to support the new dynasty, are examples. Such contemporary ones as *The Society*, or *Brothers' Club*, of which Swift was a leading light; the *Scriblerus Club*, which he actually founded; and the better remembered *Kit Cat Club*, due to Jacob Tonson's exertions, whose list of famous members, its toasts and its portraits, have made it something of a thing apart, were in the nature of literary reunions where politics occupied a subsidiary place. Nor should those associations known as *Mug House Clubs* be overlooked. The disorderly doings to which they gave rise enter largely into the social and political annals of the period, for however peaceful may have been their original intention, they degenerated into hot-beds of strife and were eventually suppressed with all the rigour of the outraged law. To call them clubs at all shows what a wide significance was given to the term, a significance still wider when we find it applied even to the disorderly illegalities of such fraternities as the notorious *Mockers*, *Scourers*, *Nickers*, *et hoc omne genus*, which made London a place of danger and fear to law-abiding citizens; and against the terrorism of which what were called *street clubs*, *i.e.*, places where the Londoner might find ready refuge, came into existence.

Of the number of clubs (so to call them) of a profane or at least eccentric character which existed at this period, the pages of *the Spectator* and the two books on the subject written by Ned Ward give sufficiently suggestive accounts. For although many of those recorded by the latter were but figments of his imagination, they were based on many actually existing, and may thus be regarded as typical. It will be recalled that it was to a club of this character held at the Boar's Head Tavern, that at a later date Johnson advised Boswell not to belong, lest it should damage his reputation.

Lesser-known clubs of the earlier half of the 18th century were *the Mourning Bush*, or, as it was afterwards re-named, *The Mountain* (it is satirically referred to by Tom Brown), of Jacobite tendencies; *The Board*, which Walpole (*Letter to Mann*, 1743) mentions; the *Coterie*, started in 1764; *The Revolution* and *the Independents*, of rather later date, but all having a marked political and even militant character.

During the second half of this period, clubs began to take on a more regularized system of life, and embraced all sorts of wants, from the famous *Dilettante Club* (still existing) and *The Thesurian*, whose names indicate their character, to the *Sons of the Thames*, a pioneer of later aquatic clubs; the *Je ne sçai quoi*, which met at the Star and Garter in Pall Mall with George, Prince of Wales, as its perpetual chairman, to the *No Pay No Liquor Club*, whose members were obliged to wear a hat of peculiar construction and to drink from a cup of peculiar shape. Such clubs were as the sands of the sea, and there could have been few directions of human interest to which one or other of them did not appeal.

But it was the literary and purely social club that is most characteristic of this period. Of the former Dr. Johnson is the protagonist. In 1748 he founded the *Ivy Lane Club*; 14 years later the far more famous *Literary Club* or *The Club*, whose annals fill so large a space in the record of his career, and which still exists, having enrolled among its members nearly all the outstanding men of two centuries. In 1783, not long before his death, Johnson founded yet another club, *The Essex Head*, so named from the tavern where its members foregathered.

Of more specialized character may be mentioned the *Royal Society Club* (1731), not, of course, to be confounded with the existing *Royal Societies Club*, parodied by Ned Ward as *The Virtuosos*; the *Noviomagians Club*, standing in the same relation to the Society of Antiquaries as the former did to the Royal Society. There were also a number of subsidiary clubs meeting at Will's and Tom's coffee-houses, in a description of which by Macky (*Journey through England*) we recognize various similarities to the club as it exists to-day. The *Sublime Society of Beefsteaks* (1735-1867), of which the present Beefsteak Club is a kind of successor; the *Robin Hood Club*, whose beginnings were in far-off days but which only emerged into prominence when Burke was an eloquent member; the *Wittanagemot*, a small and little-known society, something on the lines of our present-day dining societies, are types of the clubs of this period; while the *Blue Stockings*, of which more than one was in existence about this time (the latter half of the 18th century), formed a link between the fashionable and literary society of the day. To these may be added Goldsmith's Wednesday Club, and such quasi-debating, quasi-social institutions as the *Cogers* in the east and the *Clifford Street Club* and the so-called *King of Clubs* (1801) in the west.

With the beginning of the 19th century, clubs, as a general rule, although there had been one or two pioneers in this direction, such as White's and Brooks's, first began to have their own headquarters and consolidated themselves on those lines which in many instances still obtain. The close of the Napoleonic Wars resulted in numbers of officers of both services being at large in London, and needing centres where they could meet, and where food and general amenities could be obtained at a reasonable rate. Hence the rise of the Service clubs, which, once inaugurated, increased gradually, with the result that *The United Service* came into existence in 1815; *The Guards* in 1813; the *Junior United Service* in 1827; *The Oriental* in 1824; the *Army and Navy* in 1837; and

the *East India United Service* in 1850; to be followed by others now existing or defunct.

Regency days were, too, notable for regular gambling clubs, as differentiated from the card-playing at other centres, and *Watiers*, where Brummell was an outstanding figure, started its hectic career in 1805, which lasted till 1823, when Crockford took it, but gave it up on opening his splendid structure in St. James's street some five years later—a building which is now, after many vicissitudes, the home of *The Devonshire Club* (1875). Other small but fashionable clubs of the time were *Weltzie's* (named after a cook to the Prince of Wales) and *The Alfred* (1808), which the wits called *The Half-Read* and of which Byron was a member.

CLUBS AND THE PROFESSIONS

A change was by now coming over the institution of the club. With the increase in population and more grandiose ideas, it was found necessary to allocate such centres to varied tastes and occupations, and thus whereas previously the statesman and the soldier, the literary man and the artist, had more or less congregated in common centres, clubs specially designed for different professions and callings began to be established, and club-houses of splendid proportions sprang up under the hands of well-known architects about that area of Pall Mall and St. James's which has for long been the special home of such places. At the same time the taste for bohemianism, which reached its height during the first half of the 19th century, resulted in the foundation of a variety of clubs which enjoyed a more or less extended life, and a few of which still exist although in a gradually increasing state of sophistication. Before speaking of these, the great political clubs must be noticed. Of these, in virtue of its age and wealth of associations, comes White's, evolved from the Chocolate House of that name and started by Francis White in 1693 in a house on the site of Boodle's. Later it crossed the road to a spot now forming the northern portion of Arthur's. In 1755 another move was made, to where its rebuilt club-house now stands with all its memories of over two centuries on its head, and its famous betting book. Brooks's, which represents the opposite political camp, originated in an establishment set up by Almack (not to be confounded with his more famous Assembly Rooms, in King street) in Pall Mall under his own name, that of Brooks appearing first in 1774, four years after which date the club was moved to St. James's street, to premises built for it by Holland.

Another club which inhabits its original home is *Boodle's* (1762), first known as *The Savor Vivre*, but taking its present name from Boodle, who succeeded to the management about 11 years later. Boodle's club-house is so much in the style of the Adam brothers that it has always been regarded as their work, although there is a question as to whether or not they really had a hand in its design. It should perhaps rather be included among social clubs, such as the *St. James's* (which has also a diplomatic air), known once as the *Coventry House Club* from the beautiful mansion in Piccadilly which it has occupied since 1769, 12 years after its foundation; or *The Travellers* (another diplomatic centre) in Pall Mall, which was started in 1819, but did not blossom forth in Barry's club-house till 1832; or those other social centres such as *The Windham* (1828); *The Bachelors'* (1881); *Arthur's* (1811); *The Union* (1804), once in Pall Mall, then in Trafalgar square, and now in Carlton House terrace; the *Wellington* (1885); the *Cocoa Tree* (1746), *The Thatched House* (on the site of the famous Thatched House Tavern), which grew out of the Civil Service Club, in 1865, etc.

Of the political clubs, other than White's and Brooks's, the *Carlton* (1831) and the *Reform* (1834) are the two outstanding examples, and both occupy premises of important architectural character: the last named being probably from this point of view the most impressive structure of its kind in London. To these may be added the *Junior Carlton* (1864); the *Constitutional* (1883); the *St. Stephen's* (1870); the *National Liberal* (1882); and the *Conservative* (1840); in which connection the *Eighty* (1880); the *United* (1890); *The Cobden* (1866); and the "*1920*" Club, are among a variety of others connected with political affairs; these west-end clubs having their equivalents in the City,

where the *City Carlton* (1868); the *City Liberal*, and others, have a special object in this respect; and where the *City of London Club* (1832) and the *Gresham* (1843) are based on broader lines.

LITERARY AND ARTISTIC CLUBS

To turn to another form of specialization in this direction, there are a large number of literary and artistic clubs in London, of which *The Athenaeum* is the most important. This famous centre was founded by John Wilson Croker, at Mr. Murray's house in Albemarle street, in 1823, most of the leading literary men of the day—Scott and Moore among them—being members of the original committee. It was first (when it was called *The Society*), domiciled in Waterloo place, but in 1831 took possession of the clubhouse designed for it by Decimus Burton in Pall Mall.

Another well-known literary club is *The Savile*, or *New Club* as it was first called and generally regarded as a "waiting place" for the *Athenaeum*, which was opened in 1868 and for long occupied the small bay-fronted house in Piccadilly till it went to 69, Brook street.

A literary and artistic centre of more or less Bohemian character is the *Savage* (1857), which, after many temporary homes, has since 1890 been installed in Adelphi Terrace. Of a more theatrical character is the *Garrick* (1831). The "Little Garrick" of Thackeray, was in King street, Covent Garden, but the present premises have been occupied by the club since 1862. The *Authors' Club* is a more modern example, dating only from 1891; while *The Royal Societies Club* is three years younger.

Another phase of energy is more specially indicated by a number of clubs of which artists and connoisseurs and those interested in analogous subjects are members. Of these the *Arts Club* (1863) may be taken as the representative; as the *P.E.N. Club* (1921) may be of the more modern conception of what should be termed perhaps a working literary club.

The theatre has, too, besides the *Garrick*, a goodly array of such centres; the *O.P. Club* (1900); the *Green Room* (1877); the *Rehearsal* (1892) and the *Vaudeville* (1901) among them.

'Varsity clubs are, too, prominent, the four principal ones, restricted to members of the Universities, being the *United University* (1822); the *Oxford and Cambridge* (1830); the *New University* (1822) and the *New Oxford and Cambridge* (1883).

In another direction, that of sport, the *National Sporting Club* is dedicated to boxing; the *Sports Club* (1893) has a wider interest in varied aspects of sport; the *Turf* (1868), emanating from an earlier club known as the *Arlington*, speaks for itself as to its particular point of view; while there are various clubs specially connected with racing, such as the *Sandown*, *Hurst Park* and *Kempton Park*. The *Badminton* and the *Beaufort* have an aura of the hunting-field about them as their names connote; and such clubs as the *Coaching and Four-in-Hand*, and above all *The Jockey* (1750), which has for nearly two centuries laid down the law upon all matters pertaining to horse-racing, and has done so much to keep the turf an honourable institution, are *sui generis*. Besides these there is hardly a form of sport which does not possess its special club, from yachting in the Solent and the Thames to model yacht racing on the Round Pond in Kensington Gardens; from motoring, the *Royal Automobile Club* (1897), whose home in Pall Mall is the largest and most luxurious in London, to golfing (*The Golfers' Club*, 1893); from winter sports to dry fly-fishing; while the *Kennel Club* (1873); the *Farmers' Club* (1842); the *United Sports* (1903); the *Royal Aero Club* (1901); the *Alpine Club* (1858); the *Fencing* (1848) and *The Sword* (1905), and many others, including the *Smithfield Club* and the *Bath Club*, all attest that widespread interest in every variety of sport which has always characterized this country.

Apart from the clubs which have their own premises there are certain dining clubs inaugurated to do honour to the memory of some great man or which have for their object the bringing together, at stated intervals, of those interested in some special form of collecting. The most important of these is the *Society of Dilettanti*, dating from 1734; the collection of pictures belonging to this famous club, painted by Reynolds and Knapp, now being housed in the St. James's club, where the *Dilettanti* hold their

dinners. *Grillions Club* (1813), of which so many illustrious men have been and are members, is another example of this more intimate view of sodality approximating in many respects to the clubs of Swift and Johnson. Others of the kind are *The Roxburghe* (1812), connected with book-collecting; the *Breakfast Club* (1866), a very select society; and such specialized examples as the clubs named after Johnson and Pepys, and Butler (*The Erewhon*); Omar Khayyám and Dickens (the *Boz Club*); Rabelais and Lamb and Thackeray (*The Titmarsh*). The Sette of Odde Volumes, The Rhymers, the "Connozzers," the Grolier, the First Edition, and the Urban; The Goat and the Hardwicke (associated with the law); and so forth, represent other phases of hero worship or the worship of inanimate objects.

Many as are the existing clubs, those that during the last 100 years have arisen, flourished for awhile, and disappeared, are as numerous, some of which, like the *Arundel* and the *Raleigh*, to take but two examples, are still remembered by many.

LADIES' CLUBS

Although not exactly a new departure, one that has in recent years developed with surprising energy and completeness is the ladies' club. The earliest of these (putting aside the *Ladies' Club* of the 18th century, "the female Almacks" referred to by Walpole) was the *Alexandria* (1883), into which no man was permitted to enter (the Prince of Wales, afterwards King Edward, was once refused admittance on accompanying the Princess who was a member there, and Lord Roberts used to be seen waiting outside for Lady Roberts); then came the *Pioneer* (1892), the *Victoria*, the *New Century*, the *Halcyon*, the *Lyceum*, the *Forum*, and so on. To-day there are numbers of these clubs dedicated to the ladies or in some cases, as in that of the *Garden Club* and others, open to members of both sexes.

With regard to the internal economy of clubs, this varies as much as does the character of the aims and objects of such associations or as does the nature and architectural features of their club-houses. In some the committees possess the power of election; in others this is by ballot; some, like the *Athenaeum*, have the right of electing annually a certain number of members on account of their distinguished eminence, services to the State, literature, art, and so forth. Once a year a general meeting is held, to which a report of the annual working is submitted. The committee is a responsible body, but the conduct of the club is largely in the hands of the secretary. The law concerning clubs is to be found laid down by J. Wertheimer in his *Law relating to Clubs* (1903), and by Sir E. Carson in the chapter on the subject in his *The Laws of England* (1909). It may be noted that the Licensing Act of 1902, passed primarily to prevent clubs from being formed merely as a cloak for the sale of intoxicants, brought every club, the largest to the smallest, within its scope.

UNITED STATES

The various clubs which were formed in the United States previous to the Civil War were largely reproductions of those of England. Among these were the Old Colony Club of Boston, the Old South Club, the Puritan Club, the Temple Club and others of the same city. The Sans Souci Club of Boston (1785), and

the Turtle Club of Hoboken (1797), are names suggesting the leisure phases of life. The Union Club of New York (1836) remains as a picture of the older social type, as does the New York Yacht Club (1844). The Union League of New York was organized in 1863 to preserve the union of the States and has remained a Republican club. In opposition, the Manhattan was organized in 1865 as a Democratic club. There were in 1928 about a hundred important clubs in New York city, representing the army, the navy, the universities, finance, engineering, athletics, the arts and society. Washington is notable for its clubs, including the Army and Navy, the Cosmos, the Century, the Press, the Metropolitan, the University, the Country and the Riding and Hunt. One notable extension of the club in all large American cities has been the interchange of membership by which a member in one city may automatically become a member in another during the time of his visit. This in many instances also applies to country club facilities. Many of the larger clubs have not only their main city establishment but own country clubs as well. Principles of business organization are applied in such degree that clubs show revenues, instead of deficits, and often become wealthy through restaurant and other charges.

Among the clubs that retain the old-time flavour may be mentioned two, the Lambs', in New York, founded in 1874, and the Bohemian Club, of San Francisco, founded in 1887. The Lambs', which had in 1928 a membership of 1,650, maintains its table and its story-tellers; it is rich with kindly feelings and reveals its fund of jokes each year in its gay gambols—performances in which its wittiest and best actors take part. The Bohemian Club is frankly a place of freedom and joy. Far from the city it has its bohemian grove where, among redwood trees, its members and guests are totally free in their fun, speech and actions. The older clubs often had their inception in a spirit of fun, the wish to do something odd, unusual. One such was the Lantern Club, organized in 1893 by Edward Marshall, Stephen Crane, David Graham Phillips, Irving Bacheller and other notable writers of the day. It had its home at 32 South William street, N.Y., where had lived the famous Captain Kidd, hanged as a pirate on Bedloe's island. This club collected hundreds of ship's lanterns during its existence, and entertained many of the distinguished visitors from Europe and other lands. The United States has had its share of suicide, burial, bachelor, Dutch treat and other clubs, not unlike the Club of Ugly Faces that was formed in the early days of English clubdom. Modern clubs may be regarded as comfortable and reasonably exclusive hotels that look to the physical needs of men and women, and that may be a substitute for their homes.

The historical concept of the club, the association of a group of persons for good-fellowship, or the promotion of political and welfare aims, is found in the widely diversified clubs maintained by, or for boys, girls, women and men. The usefulness and prosperity of the club, indeed, is due to the principle of large membership drawn from people of mutual interests. This principle has led to the formation of many women's clubs. In 1867, when Charles Dickens was given a dinner in New York, at the Press Club, no women were officially placed among the guests. The year following women organized the Sorosis, which in 1889 was expanded into the General Federation of Women's Clubs. In 1928 there were more than 15,000 local clubs for women, with a membership of more than 2,500,000.

As an example of the American club idea, the Elks' may be cited. The original club was founded in New York in 1866 as a jolly group of men who wished to protest against the excise laws and who took as their emblem the head of an animal in Barnum's old museum. Gradually this good-fellowship club took on the benevolent aspects of helping its members, though never losing sight of the pleasures of informal meetings at a common place. In 1928 there were more than 1,500 of these clubs and lodges having in all a membership of 850,000. Each year millions of dollars are donated to charity by this membership. The good-fellowship club has passed from the city to the country, where members meet less frequently and for special occasions. It has become a hunting club, or a fishing club, or one of the 5,000 golf-

clubs scattered throughout the country.

The expansion of the United States overseas has led to the formation of purely American clubs after the custom of the English. There is the Army and Navy Club in Manila, the University Club at Honolulu. So there is the American Club at Mexico City, and similar clubs in London and Paris and other foreign centres. (W. S. Hr.)

CLUE or **CLEW**, the thread of life, which, according to the fable, the Fates spin for every man (O.E. *cluwe*, a ball of thread). The figurative meaning, a piece of evidence leading to discovery, is derived from the story of Theseus, who was guided through the labyrinth by the ball of thread held by Ariadne.

CLUENTIUS HABITUS, AULUS, of Larinum in Samnium, the hero of a Roman *cause célèbre*. In 74 B.C. he accused his step-father Statius Albius Oppianicus of an attempt to poison him, and Oppianicus was condemned. But there had been bribery; Cluentius was degraded, and in 66 charged with having caused his step-father to be poisoned. Cicero defended Cluentius, who was acquitted. The speech is considered one of Cicero's best, and is more quoted by Quintilian than any other.

See Quintilian, *Inst.* ii. 17, 21. Editions of the speech by W. Y. Fausset (1887), W. Ramsay (1883); see also H. Nettleship, *Lectures and Essays* (1885).

CLUJ (Ger. Klausenburg; Hung. Kolosvár), a city of Transylvania, Rumania, capital of the department of Cluj, and formerly of the principality of Transylvania. Pop. (1923), 110,000, including 34,000 Rumanians, 40,000 Magyars, 20,000 Jews, and 16,000 other nationalities, mostly German. Cluj lies mainly on the right bank of the Somos Mic, among considerable hills. On the left bank is the "Bridge Suburb" and the citadel. The streets have a modern appearance. In the central square is the fine Gothic church of St. Michael (1396-1432), and in front of it a statue of Matthias Corvinus (1902). One side of the square is formed by the Bathanyi palace, formerly of the princes of Transylvania. Other noteworthy buildings are the Reformed church, built by Matthias Corvinus in 1486 and ceded to the Calvinists by Gabriel Bethlen in 1662, containing the coats of arms of the old Hungarian dominant families, the house in which Matthias Corvinus was born (1443), now an ethnographical museum, and many palaces of the Hungarian nobility. Cluj is an orthodox bishopric, also a bishopric of the Reformed and Uniate Churches; and possesses a university, a court of appeal, a theatre, opera and several museums. Its industry includes textile, paper, sugar, candle, soap and earthenware factories, breweries and distilleries.

Cluj is believed to occupy the site of a Roman settlement named Napoca. It was colonized by Saxons in 1178, and at first enjoyed many privileges and great prosperity; but many Saxons left it in the 16th century in consequence of the introduction of Uniate doctrine, and it presently became the centre of the Magyar element in Transylvania. It was capital of Transylvania and seat of the Transylvanian diets, also under the Habsburgs, and centre of the Magyar national movement till 1918.

CLUMP, a lump, group or cluster, e.g., of trees. A clumsy shoe worn by German peasants, made from a single piece of wood; the thick extra sole added to heavy boots for rough wear. Shoemakers speak of clumping a boot when a new sole is nailed, not sewn by hand, to the old sole.

CLUNES, a borough of Talbot county, Victoria, Australia, 97½ m. by rail N.W. of Melbourne. Pop. (1921) 1,225. It is the centre of an agricultural, pastoral and mining district, in which gold was first discovered in 1851. It lies in a healthy and picturesque situation at an elevation of 1,081 feet. An annual agricultural exhibition and large weekly cattle sales are held in the town.

CLUNY or **CLUGNY**, a town of east central France, in the department of Saône-et-Loire, on the left bank of the Grosne, 14 m. N.W. of Mâcon. Pop. (1926) 3,291. The interest of the town lies in its specimens of mediaeval architecture, which include, besides its celebrated abbey, the Gothic church of Notre-Dame, the church of St. Marcel with its beautiful Romanesque spire, portions of the ancient fortifications and a number of old houses. Cluny

gradually increased in importance with the founding of the abbey (910) and the development of the religious fraternity, and in 1090 received a communal charter from the abbot St. Hugh. In 1471 the town was taken by the troops of Louis XI. In 1529 the abbey was given "in commendam" to the family of Guise. The town and abbey suffered during the Wars of Religion of the 16th century, and the abbey was closed in 1790.

The chief remains of the abbey are the ruins of the basilica of St. Peter and the abbot's palace. The church was a Romanesque building, completed early in the 12th century, and until the erection of St. Peter at Rome was the largest ecclesiastical building in Europe. It was in great part demolished under the First Empire, but the south transept, a high octagonal tower, the chapel of Bourbon (15th century), and the ruins of the apse still remain. In 1750 the abbey buildings were largely rebuilt. The abbot's palace (15th century) serves as *hôtel-de-ville*, library and museum. The town has quarries of limestone and building-stone, and manufactures pottery, leather and paper.

The Order of Cluniac Benedictines.—The Monastery of Cluny was founded in 910 by William I. the Pious, count of Auvergne and duke of Guienne (Aquitaine). The first abbot was Berno, who had under his rule two monasteries in the neighbourhood. Before his death in 927 two or three more came under his control, so that he bequeathed to his successor the government of a little group of five or six houses, which became the nucleus of the order of Cluny. Berno's successor was Odo: armed with papal privileges he set to work to make Cluny the centre of a revival and reform among the monasteries of France; he also journeyed to Italy, and induced some of the great Benedictine houses (*see* BENEDICTINES), and among them St. Benedict's own monasteries of Subiaco and Monte Cassino, to receive the reform and adopt the Cluny manner of life. The process of extension, partly by founding new houses, partly by incorporating old ones, went on under Odo's successors, so that by the middle of the 12th century Cluny had become the centre and head of a great order embracing 314 monasteries—the number 2,000, sometimes given, is an exaggeration—in all parts of Europe, in France, Italy, the Empire, Lorraine, Spain, England, Scotland, Poland, and even in the Holy Land. And the influence of Cluny extended far beyond the actual order: many monasteries besides Monte Cassino and Subiaco adopted its customs and manner of life without subjecting themselves to its sway. Fleury and Hirsau may be mentioned as conspicuous examples.

If its influence on the subsequent history of monastic and religious life and organization be considered, the most noteworthy feature of the Cluny system was its external polity, which constituted it a veritable "order" in the modern sense of the word, the first that had existed since that of Pachomius (*see* MONASTICISM). All the houses that belonged, either by foundation or incorporation, to the Cluny system were absolutely subject to Cluny and its abbot, who was "general" in the same sense as the general of the Jesuits or Dominicans, the practically absolute ruler of the whole system. The superiors of all the subject houses (usually priors, not abbots) were his nominees; every member of the order was professed by his permission, and had to pass some of the early years of his monastic life at Cluny itself; the abbot of Cluny had entire control over every one of the monks—some 10,000, it is said; it even came about that he had the practical appointment of his successor. For a description and criticism of the system, *see* F. A. Gasquet, *Sketch of Monastic Constitutional History*, pp. xxxii–xxxv. (the Introduction to 2nd ed. [1895] of the English trans. of the *Monks of the West*); here it must suffice to say that it is the very antithesis of the Benedictine polity.

The greatness of Cluny is really the greatness of its early abbots. If the short reign of the unworthy Pontius be excepted, Cluny was ruled during a period of about 250 years (910–1157) by a succession of seven great abbots, who combined those high qualities of character, ability and religion that were necessary for so commanding a position; they were Berno, Odo, Aymard, Majolus (Maieul), Odilo, Hugh, Peter the Venerable. Sprung from noble families of the neighbourhood; educated to the highest level of the culture of those times; taking part in all great move-

ments of ecclesiastical and temporal politics; refusing the first sees in Western Christendom, the cardinalate, and the papacy itself, they ever remained true to their state as monks, without loss of piety or religion. Four of them, indeed, Odo, Maieul, Odilo and Hugh, are venerated as saints.

In the movement associated with the name of Hildebrand the influence of Cluny was thrown strongly on the side of religious and ecclesiastical reform, as in the suppression of simony and the enforcing of clerical celibacy; but in the struggle between the papacy and the Empire the abbots of Cluny seem to have exercised a moderating influence. Hildebrand himself, though probably not a monk of Cluny, was a monk of a Cluniac monastery in Rome; his successor, Urban II., was actually a Cluny monk, as was Paschal II. It may safely be said that from the middle of the 10th century until the middle of the 12th, Cluny was the chief centre of religious influence throughout Western Europe, and the abbot of Cluny, next to the pope, the most important and powerful ecclesiastic in the Latin Church.

During the abbacy of Peter the Venerable (1122–1157) it became clear that, after a lapse of two centuries, a renewal of the framework of the life and a revival of its spirit had become necessary. Accordingly he summoned a great chapter of the whole order whereat the priors and representatives of the subject houses attended in such numbers that, along with the Cluny community, the assembly consisted of 1,200 monks. This chapter drew up the 76 statutes associated with Peter's name, regulating the whole range of claustral life, and solemnly promulgated as binding on the whole Cluniac obedience. But these measures did not succeed in saving Cluny from a rapid decline that set in immediately after Peter's death. The rise of the Cistercians and the mendicant orders were contributory causes, and also the difficulties experienced in keeping houses in other countries subject to a French superior. And so the great system gradually became a mere congregation of French houses, which was dissolved in 1790.

Cluniac houses were introduced into England under the Conqueror. The first foundation was at Barnstaple; the second at Lewes by William de Warenne, in 1077, and it counted as one of the "Five Daughters of Cluny." Though the bonds with Cluny seem to have been much relaxed if not wholly broken, the Cluniac houses continued as a separate group up to the dissolution, never taking part in the chapters of the English Benedictines.

Abridged accounts, with references to the most recent literature, may be found in Heimbucher, *Orden und Kongregationen* (1896), i. § 20; Herzog-Hauck, *Realencyklopädie* (ed. 3), art. "Cluni" (Grutmacher); and the *Catholic Encyclopedia*, art. "Cluny" (Seckur); *Die Cluniacenser* (1891–1894). An account is given in Maitland, *Dark Ages*, §§ xviii–xxvi. The story of the English houses is briefly sketched in the second chapter of F. A. Gasquet's *Henry VIII. and the English Monasteries* (the larger ed., 1886); *see* also the same writer's *English Monastic Life*.

CLUSERET, GUSTAVE PAUL (1823–1900), delegate for war of the Paris Commune, was born in Paris, on June 13, 1823. He was an officer of the *garde mobile* during the second republic (1848), joined Garibaldi's volunteers in 1860 and in 1861 went to the United States to take part in the Civil War. After this campaign he assumed the title of General, which he said had been granted to him personally by Abraham Lincoln. He also took part in the Fenian insurrection in Ireland of 1866–67. On his return to France he became a member of the International Working Men's Association (*see* INTERNATIONAL, FIRST), and on the news of the Commune revolt of March 18, 1871, hurried to Paris. His military title, his advanced opinions, and his presumed talents gave him great influence among the Paris workers; he was not, however, elected a member of the Commune till the supplementary elections of April 16. After the disastrous failures of Lullier and Bergeret, the Commune appointed him to the charge of the Department of War, trusting to his record and his own assertions. But, brave though he was personally, Cluseret was hopelessly unfit to organize any military operation. He failed to introduce order into his department, to prevent the continual meddling and contradiction by the central committee of the National Guard, to organize a park of artillery, or even to relieve the men in the trenches. Under his direction, with a nominal force of 100,000

wards, the defence of Paris was maintained by no more than about 10,000, usually the same 10,000. When the Commune realized the extent of his incompetence and arrested him, on May 1, the fate of the insurrection was already decided. Cluseret had been charged with treason, but his crime was inefficiency. On May 24 the entry of the Versailles troops into Paris saved him from condemnation by the Communard courts and he escaped from France. He returned in 1884, sat as deputy for Toulon in 1888-89, and died on Aug. 21, 1900. (See COMMUNE.)

See *Mémoires du Général Cluseret: le deuxième siège de Paris, la fin de l'empire* (1887-88); P. Lissagaray, *History of the Commune of 871* (1902); G. da Costa, *La Commune Vécue* (1903); R. W. Postgate, *Revolution from 1789 to 1906* (1920). (R. W. P.)

CLUSIUM (mod. Chiusi, *q.v.*), an ancient town of Italy, one of the 12 cities of Etruria, on an isolated hill at the South end of the valley of the Clanis (Chiana). It first appears in Roman history at the end of the 7th century B.C., when it joined the other Etruscan towns against Tarquinius Priscus; and at the end of the 5th century B.C. it placed itself, under its king Lars Porsena, at the head of the attempt to re-establish the Tarquins in Rome. At the time of the invasion of the Gauls in 391 B.C., the Roman envoys who had come to intercede for the people of Clusium with the Gauls took part in the battle which followed; and this determined the Gauls to march on Rome. Clusium came under Roman supremacy before 225 B.C., when the Gauls advanced thus far. The Via Cassia, constructed after 187 B.C., passed just below the town. In imperial times its grain and grapes were famous. Christianity found its way into Clusium as early as the 3rd century. In A.D. 540 it is named as a strong place to which Vitiges sent a garrison of a thousand men.

Fragments of the Etruscan town walls are built into the mediæval fortifications. Under the town extends an elaborate system of rock-cut passages, probably drains. Extensive Etruscan cemeteries surround the city on all sides. The prevalence of cremation in the early period led to the development of the so-called *tombe a ziro*, in which the cinerary urn (often with a human head) is placed in a large clay jar (*ziro*, Lat. *dolium*). This was followed by the *tombe a camera*, in which the tomb is a chamber hewn in the rock. From one of the earliest of these came the famous François vase; another is the Tomba della Scimmia (the monkey), with a painted frieze in the central chamber. The most remarkable group of tombs is, however, that of Poggio Gaiella, 3m. to the N., where the hill is honeycombed with chambers in three storeys, partly connected by a system of passages. Other noteworthy tombs are those of the Granduca, with a single subterranean chamber carefully constructed in travertine, and containing eight cinerary urns of the same material; of Vigna Grande; of Colle Casuccini (the ancient stone door of which is still in working order), with two chambers, containing paintings representing funeral rites. Nearly 3,000 Etruscan inscriptions have come to light from Clusium and its district alone, while the part of Etruria north of it as far as the Arno has produced barely 500. Among the later tombs bilingual inscriptions are by no means rare, and both Etruscan and Latin inscriptions are often found in the same cemeteries. Many inscriptions are painted upon tiles which closed the niches containing the cinerary urns. In Roman times the territory of Clusium seems to have extended as far as Lake Trasimene. The local museum contains important objects from the necropolis, *bucchero*, sepulchral urns, painted vases, and stone *cippi* with reliefs.

Two Christian catacombs have been found near Clusium, one in the hill of S. Caterina near the railway station, the inscriptions of which seem to go back to the 3rd century; another 1m. to the E. in a hill on which a church and monastery of S. Mustiola stood, which goes back to the 4th century, among its numerous inscriptions being one with the date A.D. 303, and the tombstone of L. Petronius Dexter, bishop of Clusium, who died in A.D. 322. To the west and north-west of Chiusi-at Cetona, Sarteano, Chianciano and Montepulciano other Etruscan cemeteries have been discovered; the objects from them have mostly passed to large museums or been dispersed.

See R. Bianchi-Bandinelli in *Monumenti dei Lincei* for a detailed account of the tombs; and cf. D. Randall MacIver, *Villanovans and Early Etruscans* (Oxford, 1924). (T. A.)

CLUTCH, a device by means of which connected shafts or other mechanisms, such as engaging pulleys, gears and other rotating parts, may be disconnected at will. A clutch is frequently required to operate many times in the course of a minute and, as in the spindle of the automatic screw machine, which often runs

at 5,000 r.p.m., it may be required to reverse its action several times within a few seconds. Clutches may be divided into two general classes, namely: Positive clutches and friction clutches.

Positive Clutches.—The simplest form of positive clutch is the jaw or claw type shown in fig. 1. One part of the clutch is keyed or pinned rigidly to the shaft while the other part is slotted, thus permitting it to be engaged with, or disengaged from, the first part by sliding it along the shaft. The interlocking jaws upon the abutting faces of the clutch may have various forms.

In machine tools the jaw clutch is applied extensively and is used for instantaneous disconnection of a drive to a feed screw. An automatic trip device jerks the clutch teeth out of mesh. A spiral claw clutch is utilized so that a drive cannot be reversed, this act forcing the teeth apart. Both types are shown in fig. 1.

The number of jaws on clutches depends upon the promptness with which a clutch must act. In punching and shearing machinery, the number varies from two to four, while in other classes of machinery the number of jaws may run as high as 24.

The freewheel clutch, commonly applied to bicycles, but having other mechanical applications, is another form of positive clutch. This engages the rear sprocket with the rear wheel when the pedals are rotated forwards and permits the rear wheel to revolve free from the rear sprocket when the pedals are stopped.

Friction Clutches.—The object of a friction clutch is to connect a rotating member to one that is stationary, to bring it up to speed, and to transmit the required power with a minimum amount of slippage. In connection with machine tools, a friction clutch introduces what might be termed a safety device in that it will slip when the pressure on the cutting tool becomes excessive, thus preventing the breaking of gears or other parts. According to the direction in which the pressure between the contact surface is applied, friction clutches may be further divided into axial clutches and rim clutches.

Axial clutches manufactured by the various builders of transmission machinery, machine tools and motor cars, are usually of one of the following three types: Cone, disc and combined conical disc. The cone clutch is the simplest form of friction clutch that can be devised, and if properly designed will give entire satisfaction in many mechanisms such as lathes, machine tools, hoisting apparatus, lorries, heavy automobiles. Two types of cone clutches, the single-cone and the double-cone, are usually met with. The single-cone clutch consists of a "male" cone of cast iron or specially treated steel keyed rigidly to a driving shaft with a second or "female" cone faced with cork, leather, asbestos, or other material, which is fitted to the driven shaft by means of a

FIG. 1.—(A) CLAW OR JAW CLUTCH. (B) SPIRAL CLAW, OR RATCHET CLUTCH

The oldest form, the claw or jaw clutch, can only be put in when the mechanism is running at low speed, while with the spiral clutch, the drive cannot be reversed

A spiral claw clutch is utilized so that a drive cannot be reversed, this act forcing the teeth apart. Both types are shown in fig. 1.

FIG. 2.—CONE CLUTCH FOR MOTOR LORRY OR MOTOR TRUCK

Used in machine tools, other apparatus and heavy automobiles. A lorry clutch is shown within the fly-wheel, with fabric lining riveted on

feather key. This key permits the driven cone to be engaged with the driving cone, thus transmitting the power from one shaft to the other. The hub of the driven cone is fitted with a groove into which a shifter collar is operated by the engaging lever or toggle as shown in fig. 2. When applied to vehicles the operating lever is usually replaced by a strong spring which performs the same function. The double-cone clutch is based on similar principles.

The disc-clutch—known also as the plate clutch (fig. 3)—is a series of discs arranged in such a manner that each driven disc

is located between two driving discs. The two types in common use are the single-disc in which a single disc serves as the driven member and the multiple-disc in which two or more discs act as the driven member. The single-disc clutch construction includes a fabric-faced disc which is gripped on each side between a fly-wheel or other member and a pressure disc forced up by springs, toggle levers or other devices. Multiple-disc clutches are capable of transmitting large powers at high speeds

and have wide usage in motor cars, lorries (trucks), cranes, hoists and heavy gearing. A special form of hydraulically operated disc clutch is used in some American vessels, such as torpedo boat destroyers, to disconnect the cruising engines from the turbine shafts without stopping the propelling machinery.

In addition to the asbestos-fabric faced steel disc used for the friction surfaces, the following are sometimes used: Steel against steel; steel against steel with cork inserts; steel against bronze. A combination of steel and bronze working in oil or dry steel and fabric may be used.

A combined conical-disc clutch is one in which the contact surfaces of the disc or discs are conical. In the Hele-Shaw conical disc clutch, shown in fig. 4, the driving and driven discs have a V-shaped annular groove, the sides of which form the surfaces in contact. Phosphor-bronze driving discs are provided with notches on the outer periphery which engage with suitable projections on the pressed steel casing. The mild steel driven discs have notches on the inner bore which engage with the corresponding projections on a steel spider which is splined to the shaft. The V groove in the discs permits a free circulation of oil, and at the same time ensures fairly rapid dissipation of the heat generated when the clutch is allowed to slip.

One of the recent developments with the disc type is the magnetic clutch. No toggles, lever or mechanical movements are fitted, but the friction surfaces are brought together by magnetic force when the current is switched on. As may be seen in fig. 5 the driven disc is held a little way off by a spring plate. As the coils in the driving disc are energized the resulting magnetic pull draws the driven disc against the friction lining. The magnetic pull does not attain its full value immediately and consequently the start is made without grabbing.

In the rim-clutches pressure is obtained on the periphery of a rim and the various designs are known as block, split-ring, band, and roller, depending upon the manner in which the pressure is applied to the exterior or interior of the rim. Block clutches are used chiefly on line shafts and countershafts, although there are several designs that have given good service on machine tools. Split-ring clutches are used for all classes of service but their greatest field of application appears to be in connection with machine tools, or in places where the diameter of the clutch as well as the space taken up by the clutch is limited. Band clutches are usually installed when it is necessary to transmit heavy loads accompanied by shocks, as for example, in the drives of rolling mills and heavy mine hoist. The roller clutch is used principally for punching presses.

A block clutch used for shaft work consists of a shell running

loose on the shaft, into which are fitted two brass or bronze shoes. The shoes are fastened loosely to a sleeve, which in turn is slotted to the shaft. The shoes are pressed against the inner surface of the shell by means of an eccentric screw or wedge.

The split-ring clutch consists of an outer shell running loose on a shaft or sleeve; into this shell is fitted a split-ring. The latter may be expanded by the action of a pair of levers as shown

FIG. 3.—SINGLE PLATE CLUTCH, OR DISC-CLUTCH. MUCH USED IN MOTOR CARS

FIG. 5.—VIEWS OF MAGNETIC CLUTCH, A. SHOWING CLUTCH WITH CURRENT ON. B. WITH CURRENT OFF. IN WHICH MAGNETIC PULL BRINGS SURFACES TOGETHER WHEN THE CURRENT IS TURNED ON, TRANSMITTING OVER 2,000 HORSE-POWER IN THE LARGE CLUTCHES

in the Heywood and Bridge clutch in fig. 6, or by means of a wedge. A sliding sleeve forms a convenient means of engaging a suitable lever. A sliding sleeve, operated by a suitable lever, forms a convenient means of engaging the split ring with the outer shell.

In general, a band clutch consists of a flexible steel band, either plain or faced with wood or asbestos fabric, one end of which is fixed and the other is free to move in a circumferential direction. Due to the pull exerted by the operating mechanism on the free end of the band, the latter is made to grip the driving or driven member.

The roller clutch has a cam keyed to the crankshaft on the circumference of which a number of recesses, forming inclined planes, have been cut. Rollers, rolling up these inclined planes due to the action of a shell, wedge themselves between the cam and the clutch ring, thus causing the crankshaft to rotate with a flywheel. The rollers are held in place and controlled by a shell which is connected with the crankshaft by means of a spring, which is in turn operated by a treadle.

In rolling mills a special friction clutch, known as a "coil-clutch," having a flexible steel coil connected with the driven shaft and a cone on the driving shaft has been brought into use. This type of clutch has very sensitive control. On a test made in a rolling mill, a load of 11 tons was lowered by means of a crane on to an egg without crushing it and held there for three minutes.

FIG. 4.—HELE-SHAW CLUTCH PLATES, WITH V-SHAPED GROOVES, THE ONLY PARTS MAKING FRICTIONAL CONTACT

FIG. 6.—HEYWOOD AND BRIDGE EXPANDING CLUTCH, SHOWING HOW A POWERFUL EFFECT IS GAINED BY THE EXPANDING ACTION OF RIGHT AND LEFT HAND SCREWS IN DUPLICATE: AS THE SLIDING SLEEVE IS MOVED ALONG THE SHAFT, IT WORKS THE LEVERS GIVING A PARTIAL ROTATION TO THE SCREWS, AND EXPANDS THE BAND WITHIN THE SHELL. PERMISSION OF D. BRIDGE AND CO., MANCHESTER

A special application of the block clutch is the “centrifugal-clutch” which, by utilizing the principle of centrifugal force, throws out slipper-blocks against the interior wall of the clutch to enable an electric motor to obtain a proper start before picking up the load. The weight of the shoes is so regulated that when the motor is running at full speed the power transmitted by the shoes equals the power of the motor and all slip ceases.

In motor car service, it is very desirable that the car be started without jerks. In order to secure smooth clutch engagement, the designers of clutches were compelled to originate devices that insured evenness of contact between the friction surfaces. In general the function of these devices is to raise slightly the cone facing at intervals around the periphery so that upon engagement only a small portion of the friction surface comes into contact with the flywheel rim. As soon as the full spring pressure is exerted, the facing is depressed and the entire surface of the cone becomes active. In addition to securing smooth and easy clutch engagement some means must be provided to prevent the spinning of the clutch when it is disengaged. By keeping the size and

FIG. 7.—COIL CLUTCH, WHICH CAUSES GREAT FRICTION BY THE GRIP OF THE COIL WHEN IT IS THRUST ON TO A CONE ON THE DRIVING SHAFT

weight down to a minimum spinning may be reduced slightly. To overcome the spinning action completely small brakes that are brought into action when the pedal is depressed must be provided. (F. H.)

CLUWER (CLUWER, CLUVIER, CLUVERIUS), **PHILIP** (1580-1623), German geographer and historian, was born at Danzig. He studied law at Leyden, but soon turned his attention to history and geography, which were then taught there by Joseph Scaliger. He finally settled in Holland; where, (after 1616) he received a regular pension from Leyden academy. In 1611, he

began to publish his works. He died at Leyden in 1623. His principal writings are: *Germania Antiqua* (1616), *Siciliae Antiquae libri duo*, *Sardinia et Corsica Antiqua* (1619), and the posthumous *Italia Antiqua* (1624) and *Introductio in Universam Geographiam* (1629).

CLYDE, COLIN CAMPBELL, BARON (1792-1863), British soldier, was born at Glasgow on Oct. 20, 1792. He received his education at the Glasgow high school, and when only 16 years of age obtained an ensigncy in the 9th Foot. He fought under Sir Arthur Wellesley at Vimiera, took part in the retreat of Sir John Moore, and was present at the battle of Corunna. He shared in all the fighting of the Peninsular campaigns, and was severely wounded while leading a storming-party at the attack on San Sebastian. He was again wounded at the passage of the Bidassoa, and compelled to return to England. Campbell held a command in the American expedition of 1814; and after the peace of the following year he devoted himself to studying the theoretical branches of his profession. In 1823 he quelled the negro insurrection in Demerara. In 1832 he became lieutenant-colonel of the 98th Foot, and with that regiment rendered distinguished service in the Chinese War of 1842. Campbell was next employed in the Sikh War of 1848-49, under Lord Gough. At Chillianwalla, where he was wounded, and at the decisive victory of Gujarat, his skill and valour largely contributed to the success of the British arms. He was made a K.C.B. in 1849, and specially named in the thanks of parliament.

Sir Colin Campbell returned home in 1853. In the Crimean War he commanded the Highland brigade, which formed part of the duke of Cambridge's division. The brigade and its leader distinguished themselves very greatly at the Alma; and with his “thin red line” of Highlanders he repulsed the Russian attack on Bala-klava. At the close of the war Sir Colin was promoted G.C.B.

The outbreak of the Indian Mutiny called for a general of tried experience; and on July 11, 1857, the command was offered to him by Lord Palmerston. On being asked when he would be ready to set out, the veteran replied, “Within twenty-four hours.” He left England the next evening, and reached Calcutta on Aug. 13. He started for the front on Oct. 27 and on Nov. 17 relieved Lucknow for the second time. He continued in charge of operations in Oudh until the end of the mutiny. For these services he was raised to the peerage, in 1858, as Lord Clyde; and, returning to England in the next year, he received the thanks of both Houses of Parliament and a pension of £2,000 a year. He died on Aug. 14, 1863.

See Sir Owen Tudor Burne, *Clyde and Strathnairn* (“Rulers of India” series, 1891); and L. Shadwell, *Life of Colin Campbell, Lord Clyde* (1881).

CLYDE, the principal river of Lanarkshire, Scotland (Welsh, *Chwyd*, "far heard," "strong," the *Glotta* of Tacitus), also the name of the estuary which forms the largest firth on the west coast.

The River.—Daer Water, rising in Gana Hill (2,190 ft.) on the borders of Lanarkshire and Dumfriesshire, after a course of 10½ m., and Potrail Water, rising 3 m. farther west in the same hilly country (1,928 ft.) after running north-north-east for 7 m., unite 3½ m. S. of Elvanfoot to form the Clyde, of which they are the principal headstreams, though many burns in these uplands are contributory. The old rhyme that "Annan, Tweed and Clyde rise a'out o'ae hillside" is not true, for Little Clyde Burn here referred to, rising in Clyde Law (2,190 ft.), is only an affluent and not a parent stream. From the junction of the Daer and Potrail the river runs mainly northward, but winds eastward around Tinto Hill, somewhat north-westerly to near Carstairs, where it bends west and south. From Harperfield, a point about 4 m. above Lanark, it keeps a north-westerly direction for the rest of its course as a river. The total length from the head of the Daer to Dumbarton is 106 m., and it drains an area estimated at 1,481 square m. It is thus the third longest river in Scotland (being exceeded by the Spey and Tay), but in respect of the industries on its lower banks and its sea-borne commerce, it is one of the most important rivers in the world. Near Lanark it is broken by four celebrated falls (Bonnington, Corra, Dundaff and Stonebyres Linns) within a distance of 3¼ m. Within this distance the river falls 230 ft. From Stonebyres Linn to the sea the fall is practically 4 ft. in every mile. The chief villages and towns on or close to the river between its source and Glasgow are Crawford, Lamington, New Lanark, Lanark, Hamilton, Bothwell, Blantyre and Uddingston. At Bowling (pop. 1,018)—the point of transshipment for the Forth and Clyde Canal—the river widens, the fairway being indicated by a stone wall continued seawards as far as Dumbarton. Dunglass Point, near Bowling, is the western terminus of the wall of Antoninus, or Grim's Dyke.

As far down as the falls the Clyde remains a pure fishing stream, but from the point at which it becomes an industrial river its waters are contaminated. Towards the end of the 18th century the river was yet fordable at the Broomielaw in the heart of Glasgow, but since that period the stream has been converted into a waterway deep enough to allow large ships to anchor in the harbour (see GLASGOW). Clydesdale, as the valley of the upper Clyde is called, begins in the district watered by headstreams of the river, the course of which in effect it follows as far as Bothwell, a distance of 50 m. It is renowned for its breed of cart-horses (specifically known as Clydesdales), its orchards, fruit fields and market gardens, its coal and iron mines.

The Firth.—From Dumbarton, where the firth is commonly considered to begin, to Ailsa Craig, where it ends, the fairway measures 64 m. Its width varies from 1 m. at Dumbarton to 37 m. from Girvan to the Mull of Kintyre. The depth varies from a low-tide minimum of 22 ft. in the navigable channel at Dumbarton to nearly 100 fathoms in the Sound of Bute and at other points. The Cumbraes, Bute and Arran are the principal islands in its waters. The sea lochs all lie on the Highland shore, and comprise Gare Loch, Loch Long, Loch Goil, Holy Loch, Loch Striven, Loch Riddon and Loch Fyne. The only rivers of any importance feeding the Firth are the Ayrshire streams, of which the chief are the Garnock, Irvine, Ayr, Doon and Girvan. The tide ascends above Glasgow, where its farther rise is barred by a weir. The head-ports are Glasgow, Port Glasgow, Greenock, Ardrossan, Irvine, Troon, Ayr and Campbeltown. In addition to harbour lights, beacons on rocks and light-ships, there are light-houses on Ailsa Craig, Sanda, Davaar, Pladda, Holy Isle and Little Cumbrae, and at Tumberry Point, Cloch Point and Toward Point. Health and holiday resorts on the lochs, islands and mainland coast are numerous.

CLYDEBANK, a police and municipal burgh, Dumbar-tonshire, Scotland, on the right bank of the Clyde, 6 m. from Glasgow, served by the L.N.E.R. and by the L.M.S.R. Pop. (1931), 46,963. In 1875 the district was almost purely rural, but since that date many industries have been established. Dalmuir,

Kilbowie and Yoker were included in the burgh in 1886, but in 1912 Yoker was incorporated with Glasgow. At Clydebank are large shipbuilding yards and engineering works; at Kilbowie the Singer Manufacturing company have an immense factory, and at Dalmuir are building and repairing yards of the Clyde Navigation trust. Clydebank, with Dumbarton, returns one member to Parliament.

CLYNES, JOHN ROBERT (1869—), English statesman, was born at Oldham, Lancs., on March 27, 1869, of working-class parents, and worked himself as an artisan for many years. He was active in the trade-union movement, and eventually became president of the National Union of General and Municipal Workers, and chairman of its executive council. He entered parliament as Labour member for north-east Manchester (Plating division) in 1906, and has sat uninterruptedly for the same constituency ever since. He was parliamentary secretary to the ministry of food under Lord Rhondda (1917-18), and succeeded him as minister in 1918; but resigned after the armistice.

At the beginning of the session of 1919 Clynès was elected vice-chairman of the Labour Party, and chairman in 1921, but after the election of 1922 the Labour M.P.s selected J. R. MacDonald as parliamentary leader. As deputy leader Clynès moved on Jan. 17, 1924, the Labour amendment of want of confidence in Baldwin's Government which brought that Government down and put the Labour Party in office. He became lord privy seal and deputy leader of the House of Commons. Whether leader or deputy leader of his party, Clynès always spoke in the House of Commons with moderation, and was always heard with respect. He left office in Nov. 1924.

CNIDUS, an ancient city of Caria in Asia Minor, situated at the extremity of the long peninsula that forms the southern side of the Sinus Ceramicus or Gulf of Cos. It was built partly on the mainland and partly on the Island of Triopion or Cape Krio, which anciently communicated with the continent by a causeway and bridge, and now by a narrow sandy isthmus. By means of the causeway the channel between island and mainland was formed into two harbours, of which the larger or southern, was further enclosed by two strongly-built moles. The extreme length of the city was little less than a mile, and the whole intramural area is thickly strewn with architectural remains. The walls, both insular and continental, can be traced throughout their whole circuit; and in many places, especially round the acropolis, at the north-east corner of the city, they are remarkably perfect. Our knowledge of the site is largely due to the excavations executed by C. T. Newton in 1857-1858; but of recent years it has become a frequent calling station of touring steamers. The agora, the theatre, an odeum, a temple of Dionysus, a temple of the Muses, a temple of Aphrodite and a great number of minor buildings have been identified, and the general plan of the city has been very clearly made out. The most famous statue by the elder Praxiteles, the Aphrodite, was made for Cnidus. It has perished, but late copies exist, of which the most faithful is in the Vatican gallery. In a temple-enclosure C. T. Newton discovered a fine seated statue of Demeter, which now adorns the British Museum; and about 3 m. south-east of the city he came upon the ruins of a splendid tomb, and a colossal figure of a lion carved out of one block of Pentelic marble, 10 ft. in length and 6 in height, which has been supposed to commemorate the great naval victory of Conon over the Lacedaemonians in 394 B.C.

Cnidus was a city of high antiquity and probably of Lacedaemonian colonization. Along with Halicarnassus and Cos, and the Rhodian cities of Lindus, Camirus and Ialysus it formed the Dorian Hexapolis, which held its confederate assemblies on the Triopian headland, and there celebrated games in honour of Apollo, Poseidon and the nymphs. The city was at first governed by an oligarchic senate, composed of sixty members, known as *ἀννήμονες*, and presided over by a magistrate called an *ἀρεστήρ* but, though it is proved by inscriptions that the old names continued to a very late period, the constitution underwent a popular transformation. The situation of the city was favourable for commerce, and the Cnidians acquired considerable wealth, and were able to colonize the island of Lipara, and founded the city of

Corcyra Nigra in the Adriatic. They ultimately submitted to Cyrus, and from the battle of Eurymedon to the latter part of the Peloponnesian War they were subject to Athens. In 394 B.C. Conon fought off the port the battle which destroyed Spartan hegemony. The Romans easily obtained their allegiance, and rewarded them for help given against Antiochus by leaving them the freedom of their city. During the Byzantine period there must still have been a considerable population, for the ruins contain a large number of buildings belonging to the Byzantine style, and Christian sepulchres are common in the neighbourhood. Eudoxus, the astronomer, Ctesias, the writer on Persian history, and Sostatus, the builder of the celebrated Pharos at Alexandria, are the most remarkable of the Cnidians mentioned in history.

See C. T. Newton and R. P. Pullen, *Hist. of Discoveries at Halicarnassus, Cnidus etc.* (1863).

CNOSSUS (or KNOSSOS): see CRETE.

COACH, a large roofed or enclosed carriage for passengers, which originated in Hungary at a place named Kocs, from which the name itself is derived through the French *coche*. As a general term, it is used (as in "coach-building") for all carriages, and also in combination with qualifying attributes for particular forms (as in stage-coach, mail-coach, motor-coach, etc.); but the typical coach implies four wheels, springs and a roof. The stage-coach, with seats outside and in, was a public conveyance which was known in England from the 16th century, and before railways the stage-coaches had regular routes (stages) all over the country; through their carrying the mails (from 1784) the term "mail-coach" arose. Similar vehicles were used in America and on the European continent. The *diligence*, though not invariably with four horses, was the Continental analogue for public conveyance, with other minor varieties such as the *Stellwagen* and *Eilwagen*.

The driving of coaches with four horses was a task in which a considerable amount of skill was required, and English literature is full of the difficulties and humours of "the road" in old days. A form of sport thus arose for enterprising members of the nobility and gentry, and after the introduction of railways made the mail-coach obsolete as a matter of necessity, the old sport of coaching for pleasure still survived, though only to a limited extent. The Four-in-Hand Club was started in England in 1856 and the Coaching Club in 1870, as the successors of the old Bensington Driving Club (1807-52), and Four-Horse Club (1808-29); and in America

by springs, but hung on leather straps; and the whole structure is very richly loaded with ornamental carving, gilding and paint-work. The different panels and the doors contain various allegorical groups of figures representing suitable subjects, and heraldic devices painted in a spirited manner. The royal state coach, which is described as "the most superb carriage ever built," was designed by Sir William Chambers, the paintings on it were executed by Cipriani, and the work was completed in 1761. During the later part of Queen Victoria's reign it was hardly ever seen,

THE BRITISH ROYAL STATE COACH, COMPLETED IN 1761

This coach is used only for ceremonial occasions such as the opening of parliament. The panels and door are covered with emblematic devices

but on the accession of Edward VII. the coach was once more put in order for use on state occasions. The following is an official description of this famous coach:

"The whole of the carriage and body is richly ornamented with laurel and carved work, beautifully gilt. The length, 24 ft.; width, 8 ft. 3 in.; height, 12 ft.; length of pole, 12 ft. 4 in.; weight, 4 tons. The carriage and body of the coach is composed as follows:—Of four large tritons, who support the body by four braces, covered with red morocco leather, and ornamented with gilt buckles, the two figures placed in front of the carriage bear the driver, and are represented in the action of drawing by cables extending round their shoulders, and the cranes and sounding shells to announce the approach of the monarch of the ocean; and those at the back carry the imperial fasces, topped with tridents. The driver's foot-board is a large scallop shell, ornamented with bunches of reeds and other marine plants. The pole represents a bundle of lances; the splinter bar is composed of a rich moulding, issuing from beneath a voluted shell, and each end terminating in the head of a dolphin; and the wheels are imitated from those of the ancient triumphal chariot. The body of the coach is composed of eight palm-trees, which, branching out at the top, sustain the roof; and four angular trees are loaded with trophies allusive to the victories obtained by Great Britain during the late glorious war, supported by four lions' heads. On the centre of the roof stand three boys, representing the genii of England, Scotland and Ireland, supporting the imperial crown of Great Britain, and holding in their hands the sceptre, sword of state, and ensigns of knighthood; their bodies are adorned with festoons of laurel, which fall from thence towards the four corners. The panels and doors are painted with appropriate emblematic devices, and the linings are of scarlet velvet richly embossed with national emblems."

We may observe how the difficult art of driving a coach was responsible for the use of the terms "coach" and "coaching" to mean tutor or training for examinations or athletics.

See the *Badminton Driving*, by the duke of Beaufort (1888); Roger's *Manual of Driving* (Philadelphia, 1900); and "Nimrod's" *Essays on the Road* (1876).

COACHING. The 20th century witnessed in its first quarter the passing of a style of conveyance which was at one time universal, and has inspired the artist, the poet and the author to work that will remain long after the last coach has ceased to be seen on the roads. To say that four-in-hand driving will die out entirely is to take an extreme view, but while railways and motor cars hold their own there will be little chance for the art on our country roads—at any rate in comfort.

The reader need hardly be told that in early days the roads were so bad in Great Britain that wheeled traffic literally made slow progress, and nearly everybody rode; but towards the end of the Commonwealth period social life had demanded a better means of communication from place to place. Accordingly the stage coach made its general appearance, and in spite of a good

STATE COACH OF THE LORD MAYOR OF LONDON, BUILT IN 1757

the New York Coaching Club was founded in 1875. But coaching remains the sport of the wealthier classes, although in various parts of England (e.g., London to Brighton, and in the Lake district), in America, and in Europe, public coaches still have their regular times and routes for those who enjoy this form of travel. The earliest railway vehicles for passengers were merely the road coaches of the period adapted to run on rails, and the expression "coaching traffic" is still used in England to denote traffic carried in passenger trains.

Of coaches possessing a history the two best known in Great Britain are the king's state coach, and that of the lord mayor of London. The latter is the older, having been built, or at least first used, for the procession of Sir Charles Asgil, lord mayor elect, in Nov. 1757. The body of this vehicle is not supported

deal of opposition, and the usual charge of effeminacy, remained. As might be expected the pace for many years was not great, and at first the coaches travelled only by day, the "flying coaches," as they were called, covering between forty and fifty miles in the day of 12 hours—in fine weather.

It must be remembered that coaching even in its palmy days had its detractors, for the weather had to be taken into consideration, while the roads themselves till the days of Telford and Macadam left much to be desired, and accidents were much more numerous than is the case to-day with railways. Still its utility was beyond argument, but the question of speed arose, and it should also be borne in mind that the slowness of the pace rendered the stage coach an easy prey to the highwaymen, who then abounded. The post office at the time favoured the plan of mounted "expresses," and the slowness of the postal service was especially noticeable on the Great North Road, it being said that "every common traveller passes the King's Mail on the first road in the kingdom." Indeed at that time the stage coach itself was a speedier conveyance than the ordinary postal system.

The moment brought the man, and it was John Palmer, the proprietor of the theatre at Bath, who in 1784 put the first mail coach on the road, running from Bristol to London at the rate of about seven miles an hour. The mail coach speedily found favour, and, as its name implies, it may be termed the special *protégé* of the post office; of course it did not exterminate the stage coach, the two existing side by side till the advent of railways drove them both off the road together.

The driving of four horses appealed to the sporting gentlemen of the day, who drove their own vehicles, or who would take a stage or two on the regular coaches, with the connivance of the professional driver. Some well-known amateur coaching clubs were formed, including the Four Horse and the Bensington driving clubs, both of which in due course passed away. It was in 1856 that the Four-in-Hand driving club was formed and lasted down to 1927, while in 1870, owing to the Four-in-Hand driving club only receiving a limited number of members, the still existing coaching club was established. Though its members do not turn out in as great numbers as they did, it still keeps the spirit of the pastime alive at the meets at the Magazine in Hyde Park. Here, however, the pleasure of driving four horses is the only consideration and no "passengers" are taken for remuneration.

Later on a number of what may be termed subscription coaches were placed upon the road, which usually ran to various places within a radius of something like 50 miles of London, and till the appearance of the motor car they were very popular. They have, however, practically disappeared, with the death of the last of the London enthusiasts who was able to indulge his hobby, though two roads were kept open in 1927.

In the past many private gentlemen, especially masters of hounds, would indulge in driving tours through various parts of the country, and in 1926 one well known master in the North afforded his friends and subscribers a very pleasant afternoon's outing. At the holding of some of the great horse shows, notably Richmond and Olympia, coaching classes are popular and often well patronised, for it must be remembered that the regimental coaches, that is coaches kept up by various regiments in the service, have not yet gone out of fashion. Indeed it will probably be very many years before the art of driving four horses is lost entirely in Great Britain. (See DRIVING.)

The great enemy of the harness horse to-day is the motor car, to assist which tarred roads have been laid down. This undoubtedly adds to the discomfort of driving, and horse vehicles of all descriptions are becoming scarcer every year, except for slow work or where constant stoppage is necessary. Still, the coaching period has been a brilliant one, and its passing will be regretted by every lover of the horse.

COAHUILA, a northern frontier State of Mexico, bounded N. and N.E. by Texas, U.S.A., E. by Nuevo León, S. by San Luis Potosí and Zacatecas, and W. by Durango and Chihuahua. Area, 58,067 sq.m. The population in 1921 was 393,480. Its surface is a roughly broken plateau, traversed by several ranges of mountains and sloping gently toward the Rio Grande. In the

western part there exist extensive areas of level land, many of them enclosed drainage basins, the largest of which is the Bolsón de Mapimí, a great depression which was long considered barren and uninhabitable. Experiments with irrigation, however, have been highly successful and considerable tracts have since been brought under cultivation. In general the State is insufficiently watered, the rainfall being light and the rivers small. The rivers flow eastward to the Rio Grande. The climate is hot and dry, and generally healthy. Stock-raising was for a time the principal industry, but agriculture has been largely developed in several localities, among the chief products of which are cotton—Coahuila is the principal cotton-producing State in Mexico—Indian corn, wheat, beans, sugar and grapes. The Parras district in the southern part of the State has long been celebrated for its wines and brandies. The mineral products include silver, lead, coal, copper and iron. The mining operations are chiefly centred in the Sierra Mojada, Sierra Carmen and in the Santa Rosa valley. The modern industrial development of the State is due to the railway lines constructed across it during the last quarter of the 19th century, and to the investment of foreign capital in local enterprises. The first Spanish settlement in the region now called Coahuila was at Saltillo in 1586, when it formed part of the province of Nueva Viscaya. The capital of the State is Saltillo. Among the more important towns are Parras, pop. (1921) 7,284, 98m. W. by N. of Saltillo, one of the largest railway centres in the country, and Piedras Negras (formerly Ciudad Porfirio Díaz) on the Rio Grande.

COAL AND COAL MINING. By coal is comprehended all the fossil fuels contained in the earth's crust. Being an amorphous substance of variable composition it cannot be as strictly defined as can a crystallized or definite mineral. Coal, strictly speaking, is not a mineral but a rock, and, further, it is a sedimentary rock; the mineral substance, consisting mainly of complex carbon compounds, is amorphous. There is no standard coal: there is an almost endless series of varieties, from brown coal at the one extreme to anthracite at the other; and even the brown and the anthracite vary greatly in character and composition as do all the coals coming between them. Peat is sometimes included under the term coal, but erroneously so, seeing it cannot be regarded as a fossil fuel.

The substance coal has been known in the common language of Britain from earliest historical times by specific names. That the ancient Britons in general were acquainted with coal as such is evident from its appellation at the present time, which is not Saxon but British, and subsists among the Irish as *gual*, amongst the Cornish in *kolan* and in Welsh as *glo* to this day. That the word *kohle* to designate coal was in general use in England before the Norman invasion is proved by the fact that the French (*charbon*) or Latin (*carbo*) name was not adopted. The derivation is referable to a pretty widely spread root signifying simply "black," e.g., the Arabic *kaldá*, Turkish *kará* (thus *Kara-on*, the black water; *Kará Denghoz*, the Black Sea, etc.), the Greek *κελαινος*, used by Homer for black. The spelling "cole" or "coalle" was generally used up to the middle of the 17th century, when it was gradually superseded by the modern form "coal."

The word anthracite—a form of coal of high fixed carbon content—is from the Greek *ἀνθρακίτης*. About 371 B.C. Theophrastus, pupil of Aristotle, uses the word in his treatise "On Stones," where he mentions fossil substances "that are called coals, which kindle and burn like woodcoals." "These are found in Liguria and in Elis, in the way to Olympias, over the mountains; they are used by the smiths." This is probably the earliest mention of true coal (not charcoal) on record. The term *lithanthrax*, stone coal, still survives, with the same meaning, in the Italian *lithanthrace*. The first record of the use of coal in Great Britain is frequently stated to be in A.D. 852, when it is recorded in the Saxon Chronicle of the Abbey of Peterborough that the Abbot Ceobred let the land of Sempringham to Wulfred, who was to send each year to the monastery "60 loads of wood, 12 loads of coal, 6 loads of peat, etc." It is most probable, however, that the Romans were acquainted with the use of coal during their occupation of Britain from the fact that we find coal cinders among the ruins

of Roman towns, forts and villas, especially in Northumberland in the neighbourhood of the Roman Wall, near to the course of which well-known seams outcrop.

In the following pages the subject of coal and coal mining in all its aspects is treated under the following headings:—

- Section I.—*Coal: Origin and Occurrence; Composition and Varieties; Chemical and Physical Characteristics.*
 " II.—*The World's Coal Reserves; Output, Consumption and Production Costs.*
 " III.—*Utilization and Conservation of Coal; Electrical Power Uses; Coal Carbonization.*
 " IV.—*Coal Miners: Their Characteristics and Occupations.*
 " V.—*Coal Mining: The Actual Operations; Colliery Outputs.*
 " VI.—*Coal Mining Accidents and their Prevention; the Record of Casualties.*
 " VII.—*Lignite: Its Production and Utilization.*
 " VIII.—*Coal: Its Sale, Distribution and Export.*
 " IX.—*Coal: History of Legislation and Commissions of Enquiry.*
 " X.—*Coal: The Question of Nationalization.*
 " XI.—*Coal: Control Methods in the World War.*
 " XII.—*Coal Industry: United States.*

SECTION I.: COAL: ORIGIN AND OCCURRENCE; COMPOSITION AND VARIETIES; CHEMICAL AND PHYSICAL CHARACTERISTICS

Coal is the outcome of a process of transformation whereby the oxygen and hydrogen contained in the woody fibre and other vegetable matter are eliminated in proportionally larger quantity than carbon, so that the percentage of the latter element is increased. This is excellently demonstrated in the following table prepared by the late Dr. Percy. The mineral matter is also changed by the removal of the silica and alkalis and the substitution of substances analogous in composition to fireclay.

Composition of Fuels (Assuming Carbon=100)

| Substance | Carbon | Hydrogen | Oxygen | Dispos- able hydrogen |
|--|--------|----------|--------|-----------------------------|
| Wood | 100 | 12.18 | 83.07 | 1.80 |
| Peat | 100 | 9.85 | 55.67 | 2.89 |
| Lignite | 100 | 8.37 | 42.42 | 3.07 |
| Thick coal of South Staffordshire | 100 | 6.12 | 21.23 | 3.47 |
| Hartley steam coal | 100 | 5.91 | 18.32 | 3.62 |
| South Wales steam coal | 100 | 4.75 | 5.28 | 4.09 |
| American anthracite | 100 | 2.84 | 1.74 | 2.63 |

The causes and methods of these changes are not yet fully understood; indeed, perhaps of all the problems connected with the natural history of coal we know least about the means of its conversion, although the researches of B. Renault ("Sur quelques Micro-organismes des combustibles fossiles," *Bull. Soc. Indust. Miner.*, Sér. 3, vol. xiii, p. 868, 1899; vol. xiv, p. 5, 1900, and "Recherches sur les Bactériacées fossiles," *Ann. Sci. Nat.*, Sér. 8, Bot. vol. ii, p. 275, 1896) have gone a long way towards helping us to an understanding of the processes involved in the transformation of the original vegetable matter into coal. The product coal is evidently the result of biochemical action, the agents of the transformation of the cellulose into peaty substance being saprophytic fungi and bacterial ferments. The ultimate term of bacterial activity seems to be the production of ulmic acid, containing carbon 65.31% and hydrogen 3.85%, which is a powerful antiseptic. By the progressive elimination of oxygen and hydrogen, partly as water and partly as carbon dioxide and marsh gas, the ratios of carbon to oxygen and hydrogen in the reduced product increase according to the age of the formation in the following manner:—

| | C:H | C:O |
|------------------------------|------|-----|
| Cellulose | 7:2 | 0:9 |
| Peat | 9:8 | 1:8 |
| Lignite, imperfect | 12:2 | 2:4 |
| Lignite, perfect | 12:6 | 3:6 |

The resultant product of the action of the bacteria and fungi is a brown pasty or gelatinous substance which binds the more

resisting parts of the plants into a compact mass.

It would certainly seem beyond dispute that these extremely microscopic organisms existed in carboniferous times, particularly in the case of some coprolites or fossilized excreta of Permo-Carboniferous fish or reptiles, for in them Renault and Prof. Bertrand demonstrated the actual bacillus. But apart from actual identification of the bacteria, there appears almost conclusive evidence to the effect that the tissues, included in the plant petri-factions, exhibit all the indications of cells attacked and destroyed

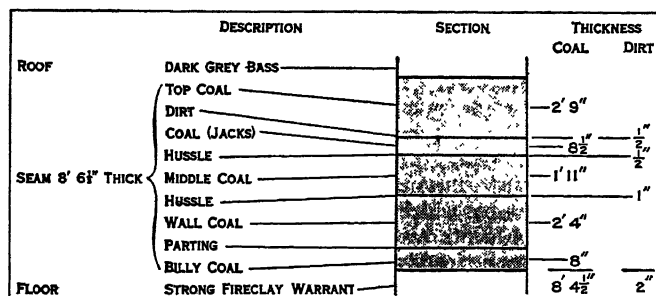

FIG. 1.—CHARACTERISTIC SECTION OF BULLHURST SEAM AT SILVERDALE COLLIERY, NORTH STAFFORDSHIRE, ENGLAND

by bacteria. The brown or black opaque ground substance of the coal is to be accounted for as the final product of the destruction of the tissues by the bacteria.

Laboratory research has shown that the alkalinity of a medium can be maintained for a considerable length of time by the hydrolysis of sodium-clay, and that a roof containing hydrolysing sodium-clay is impermeable to gases and water; that the conditions under such a roof are what is termed anaerobic (non-aerated), and that the alkaline medium produced under such a roof is suitable for continuous decomposition of organic matter. An examination of roofs of coal seams has shown that they are alkaline and contain sodium-clay. Mature leaves have been submitted to bacterial decomposition under a sodium-clay roof, with the result that the residual solid product was black and possessed the typical fusain structure. (E. Mackenzie Taylor, "Base Exchange and the Formation of Coal," *Nature*, vol. cxx, pp. 448, 449, 1927.)

The actual conversion of this product into coal, it is supposed, is due to what is termed regional metamorphism. The mass of decomposed vegetable matter being over-laid by the deposition of layers of sand and mud due to the sinking of the land, it is subjected to an ever increasing weight of superincumbent strata compressing it into a much smaller compass and profoundly affecting it in other ways. We know, also, that towards the close of Palaeozoic times the regions occupied by the British coalfields were subjected to great earth movements due to volcanic disturbance, to such an extent that the horizontal deposits—coals, sandstone and shale—became tilted, faulted, folded or contorted. The sandstones and shales, being hard rocks, were not altered structurally to any great extent, but the comparatively soft altered vegetable layers, as the result of the pressure and the heat caused by the pressure, would undergo great physical and chemical changes. The changes due to these geological causes have been rapidly accomplished, as pebbles of completely formed coal are found sometimes in the sandstones and coarser sedimentary strata alternating with the coal seams in many coalfields.

Different views have, from time to time, been held as to the nature and growth of the plant life which constitutes the mother substance of the coal seams. In 1870, Huxley, in an article in the *Contemporary Review*, described the "Better Bed" coal seam of Bradford, Yorkshire, as being composed chiefly of sporangia and spores, but as Prof. W. C. Williamson of Manchester afterwards showed him, the sporangia were really megaspores of cryptogamic plants. Megaspores (female spores) and microspores (male spores) are very largely in evidence in British and many other coals, whereas in some others no trace of spores can be found. Woody matter must have entered very largely into the composition of the original vegetable mass of some coals, as for instance the coalfield of St. Etienne in Central France, where, as M.

Grand' Eury has shown, some of the coals are homogeneous deposits composed of the bark of Cordaites, or of species of Calamites. Dr. Marie Stopes has shown the same to be true of many British coals. According to Goeppert, seams of coal in Upper Silesia appear to be largely, if not entirely, composed of Sigillarian wood, impressions of the bark of this plant, and sometimes impressions of the leaves, being recognized between the layers of coal.

It is clear, therefore, that coal is made up of many constituents: (a) woody or xyloid substances, which are so characteristic of lignite coal, called by some "anthraxylon" (from *anthrax*, coal, and *xylon*, wood); (b) cannelloid material, consisting largely of spores of cryptogamic plants, of which cannell coal is chiefly composed; (c) resinous matter, occurring largely in lignites but rarely in cannels; (d) macerated material mixed with woody matter and best described as débris, as it contains all the previously mentioned substances; (e) the "fundamental matter" of White and Thiessen, which is the colloidal ground mass in which the other constituents are embedded, and which is composed chiefly of the more readily decomposable parts of the vegetable matter. The vegetable constituents of coal are, therefore, cellulosic and resinous.

A seam of coal—quite apart from the interstratified thin bands of argillaceous or more rarely of arenaceous matter (which occur in the case of many coal seams—layers variously termed bands of "dirt," "clod," "clift," "hussle," or "stone")—consists of layers of different classes of coal, a seam seldom being homogeneous in point of chemical composition or physical character throughout. But even where the seam comprises but one class of coal, as has been long known, it is made up of laminae of "bright coal" (the *Glanz Kohle* of Germany) and "dull coal" (*Matt Kohle*), the laminae being divided by an amorphous powdery substance known as "mineral charcoal." Of late years, and for no very obvious reason, it has become customary to designate these varieties by the French words "vitrain" and "clarain" for the bright coal, "durain" for the dull coal, and "fusain" for the mineral charcoal. The exact origin of these substances, which vary in composition, is not quite clear. Thus the following is a typical section of the Bullhurst seam of coal at the Silverdale colliery in North Staffordshire (see fig. 1):—

| Description | Thickness | |
|-----------------------------------|-----------|---------|
| | Coal | Dirt |
| | ft. in. | ft. in. |
| Roof—Dark grey bass: | | |
| Top coal | 2 9 | |
| Dirt | | .. ½ |
| Coal (jacks) | 0 8½ | |
| Hussle | | .. ½ |
| Middle coal | 1 11 | |
| Hussle | | 1 |
| Wall coal | 2 4 | |
| Parting | | |
| Billy coal | 0 8 | |
| Floor—Strong fireclay warrant . . | 8 4½ | 0 2 |

In this seam several classes of coal are divided from each other by thin strata of argillaceous (shaly) matter, the coal itself being composed of bright and dull coal with interposed bands of mineral charcoal.

The Formation of Coal Seams and Variation in the Character of Coal.—It might naturally be supposed that if the origin of the coal seams was the same in each case, that is to say, if they were the result of the submergence of forests of cryptogamic and cotyledonous plants, in point of chemical composition there would be no, or at any rate almost imperceptible, variation; but such is not the case. Not only is there variation in composition as between different coal seams, but the same seam in a given coalfield in some cases—notably in South Wales—shows considerable variation in different areas.

A given seam may—frequently does—vary in character vertically and laterally. The reason for the variation in the character

of the coal in the different horizons of a given seam, and in the genus of the plant remains, may probably be explained to some extent by what is to be observed in some peat bogs (F. J. Lewis, "The Plant Remains in the Scottish Peat Mosses," *Trans. Roy. Soc. Edinburgh*, vols. xli.; xlv.; xlv.; 1906, 1907), where the sequence can be diagrammatically represented in the following manner (see fig. 2):—

| | |
|--|---|
| Upper Turbarian or Sixth Glacial Stage | Recent peat chiefly <i>Scirpus</i> and <i>Sphagnum</i> |
| Upper Forestian | <i>Pinus sylvestris</i> <i>Sphagnum</i> <i>Eriophorum</i> |
| Lower Turbarian or Fifth Glacial Stage | Arctic Willow and <i>Eriophorum</i> <i>Eriophorum</i> <i>Sphagnum</i> |
| Lower Forestian | <i>Betula alba</i> <i>Salix</i> and <i>Calluna</i> |
| Fourth Glacial Stage | Coarse sand Morainic material |

With regard to lateral variation, in some cases, undoubtedly, the change is properly attributable to metamorphism consequent upon igneous intrusion, earth movements, and other kinds of geothermic action, causing greater or less loss of volatile constituents during, or it may be subsequent to, the period of coal transformation, conditioned by differences of permeability in the enclosing rocks, which is greater for sandstones than for argillaceous strata; but these agencies would not meet the whole problem and none of them appears to be applicable over more than comparatively limited areas. In the investigation of this problem of difference, we are inevitably forced to consider the question of the mode of formation of coal seams.

There are in this connection two schools of thought, that which advocates the terrestrial theory, that is, the accumulation of the vegetable matter on dry or marshy land and its subsequent submergence, sometimes termed the "growth in place," "the peat to anthracite theory," as Arber terms it. "This hypothesis," he says, "assumes that all coals 'started life,' so to speak, with an initial stage of Peat. The Peat later became converted into Brown coal, next Brown coal passed into Humic or Bituminous coal, and finally, at least in some cases, Anthracite resulted." This was the original and most commonly accepted explanation of the origin of coal, but there have always been those who advocated another theory, namely, that known as the "drift theory," which asserts that the material which formed the coal seams was drifted into position, being transported from a distance. This explanation of the mode of formation of coal seams was advocated by H. Link as far back as 1838.

The advocates of the *in situ* theory point to the Great Dismal Swamp of North Carolina and Virginia and to the great peat beds of Northern Europe. The Dismal Swamp is a fresh-water swamp of peat and forest, the area of the inundated portion of which is about 38 m. north and south by 25 m. east and west (N.S. Shaler, "Geology of the Dismal Swamp District of Virginia and North Carolina," *U.S. Geol. Survey*, Tenth Ann. Rept., pt. 1, pp. 313–339, 1888–89), and was extending its borders before drainage and cultivation by man began. Osborne estimates that the original area of the Swamp was 2,200 sq.m., of which 700 have now been drained. (C. C. Osborne, "Peat in the Dismal Swamp, Virginia and North Carolina," *U.S. Geol. Survey, Bull.*, 711-C. 1919.) Shaler outlines the series of geological events in connection with this swamp as follows: (1) a subsidence causing the formation of the Pliocene plateau, (2) elevation permitting of erosion of the Plateau, (3) subsidence permitting of the deposition of non-fossiliferous sands, (4) elevation permitting carving of the surface, (5) subsidence and the formation of the nausemond escarpment, (6) re-elevation and development of valleys and streams, (7) sinking now taking place.

The late Sir Charles Lyell, writing in 1845 in his *Travels in North America, Canada, and Nova Scotia, with Geological Observations*, describes the possible formation of coal seams as follows:

"Huge swamps in a rainy climate, standing above the level of the surrounding firm land, and supporting a dense forest, may have spread far and wide, invading the plains, like some European peat-mosses when they burst; and the frequent submergence of these masses of

vegetable matter beneath seas or estuaries, as often as the land sunk down during subterranean movements, may have given rise to the deposition of strata of mud, sand or limestone immediately upon the vegetable matter. The conversion of successive surfaces into dry land, where other swamps supporting trees may have formed, might give origin to a continued series of coal measures of great thickness."

A possible explanation of the variation in quality of the coal in the same seam is afforded by Lemièrre in the *Bulletin de la Société de l'Industrie Minérale*, Sér. 4, vol. iv., pp. 851 and 1299, vol. v., p. 273, where he maintains that the differences in composition are mainly original, the denser and more anthracitic varieties representing plant substance which has been more completely macerated and deprived of its putrescible constituents, before submergence, or of which the deposition had taken place in shallow water more readily accessible to atmospheric oxidizing influences than the deeper areas where conditions favourable to the elaboration of compounds richer in hydrogen prevailed.

On the other hand the advocates of the drift theory say, (1) seeing that the great mass of the rocks forming the coal measure series are formed of water-borne and water-deposited material, it is only reasonable to suppose that coal was likewise so borne and deposited; (2) that the areas occupied by the coal-bearing rocks are too extensive to have originated under estuarine conditions such as exist to-day; (3) that coal is usually a stratified rock, and so it would be were it derived from drifted material; and (4) that the splitting up of seams is difficult to account for under the *in situ* theory, but is explainable under the drift theory. These are, perhaps, the chief arguments advanced against the growth *in situ* theory. Probably both theories are applicable; some coalfields being formed *in situ*, others being the result of water-borne and water-deposited vegetable matter. Certainly the carbonaceous material in the small coalfields in south-western France, deposited in basins formed in the metamorphic rocks and resting directly thereon without the intervention of sedimentary rocks was water-borne; and it is possible that the coal seams in Natal are likewise the result of vegetable matter carried and deposited by water—to mention two cases; but the evidence in favour of the growth *in situ* of many, and especially in respect of the British, coalfields of the Carboniferous period would appear to be overwhelming. E. A. Newell Arber, in *The Natural History of Coal* (1911, pp. 115–118), has put forward a possible explanation of the origin of estuarine coals, and an explanation of the varied nature of the flora of a coal seam based on the belief that the material may have originated partly *in situ* and partly from drifted vegetation. He points to the fact that the carboniferous period was admittedly one of "ups and downs," the surface of the land either slowly sinking or being gradually raised, there being a great number of these alternating periods; that during periods of elevation, the surface was covered with dense vegetation of varied forms, tree forms predominating. He thinks there is no reason why such typical representatives of the classes Lycopodiales, Cordaitales and Pteridospermeae as *Lepidodendron*, *Cordaites* and *Lyginodendron* should have been confined to marshes, and that there were in Carboniferous times as now varied upland associations as well as hygrophytic and halophytic, lowland assemblages. During periods of elevation, there existed, as to-day, fresh-water, brackish-water, or marine conditions. When the land began to sink two changes took place: the estuaries and swamps were invaded, becoming salt and brackish instead of, as formerly, brackish and fresh water, and secondly, the swamps invaded those portions of the land which were formerly elevated ground but were now sinking. Consequently, large areas of almost level surface sank to near sea-level, or even below, and the boundaries of the future coalfield were initiated. The extent of the existing delta and fresh-water swamps became greatly magnified, and they were finally merged into one great swamp, and on this area vegetable débris accumulated. The débris, which accumulated on the floor of the submerged surface would be almost entirely derived from vegetation, as owing to the subsidence of the land the streams would deposit their loads of earthy detritus far inland, and not as formerly at their mouths, now submerged. So an accumulation of purely vegetable origin would result, just as is found to-day in the Great Dismal Swamp. This accumulation

would be derived in part from the former vegetation which grew *in situ* and was essentially of an estuarine character, and in part from plants which still flourished on the sinking land; in addition to which the vegetation from the higher lands became involved, for the trees there could no longer flourish on invasion by the swamp.

Mineral Matter Contained in Coal Seams.—Besides the purely carbonaceous matter constituting what we understand by the term coal, there is a variable quantity of mineral matter which goes to form the ash. This foreign matter consists of silica, calcite, gypsum, ankerite, barytes, iron, iron-pyrites and phosphorus. The gypsum, calcite, ankerite and barytes occur in thin films in the divisional planes, vertical and horizontal, of the coal. It remained for Crook (T. Crook, "On the frequent occurrence of Ankerite in Coal," *Mineralogical Magazine*, vol. xvi., No. 75, pp. 219–223, 1912) to show that the white carbonate (commonly referred to by scientific writers on coal as calcium carbonate) which is so common in coals, and is peculiarly characteristic of the steam coals of Northumberland, is in point of fact the mineral ankerite, the amount of free calcite being comparatively small. These sheets or plates of ankerite, with which are associated calcite, barytes, pyrites, and even zinc blende and galena in very small quantities are less than a millimetre in thickness and constitute minute mineral veins. As a rule the dominant mineral is ankerite. The pyrites also occurs in divisional planes in the coal, though in the form of marcasite (a form of iron pyrites which crystallizes in prisms and is paler than "pyrite," which crystallizes in cubes); it is dispersed throughout the coal substance.

In small part these impurities are derived from the original vegetation itself, e.g., to some extent the sulphur and silica. Decaying vegetable matter has the property of converting the iron in its composition into iron pyrites, but the sulphur may, in part, have an extraneous origin and be due to the infiltration of mineral solutions from overlying rocks. As Thiessen has pointed out, sulphur exists in the proteins of practically all plants and there is in addition some non-protein sulphur in the majority of plants. Moore divides the sulphur contained in coal into inorganic and organic, pointing to the fact that, as has been recognized for many years, a portion of the sulphur contained in coal must exist in some form other than mineral sulphides and sulphates, as in some coals it does not exist in such proportions as can be combined with the elements necessary to form these mineral com-

FROM LEWIS, "PLANT REMAINS IN THE SCOTTISH PEAT MOSSES" (ROYAL SOC. OF EDINBURGH)
FIG. 2.—DIAGRAM SHOWING A SECTION OF A PEAT BOG IN KIRKCUDBRIGHTSHIRE AND AYRSHIRE, SCOTLAND

pounds (E. S. Moore, *Coal*, pp. 33–34, 1922). The inorganic type is most common. The sulphur exists as sulphide or sulphates—chiefly the former—usually of iron, and as free sulphur, and is very detrimental to smelting and gas making.

The occurrence of phosphorus in coal may be due in part to the infiltration of water from rocks containing calcium phosphate, but some of it, at any rate, is derived from the vegetation itself, for spores are known to contain phosphorus. It occurs only in minute quantity in coal, but that quantity is very detrimental in coal or coke used for metallurgical purposes.

Hydrocarbons, such as petroleum, bitumen, paraffin, etc., are found occasionally in coal seams, but more generally in the asso-

ciated strata of sandstones and in the lower carboniferous limestones. Gases, consisting principally of methane (light carburetted hydrogen or marsh gas) are commonly present in an occluded form, sometimes existing under conditions of considerable pressure, in the coal, and constituting a most formidable danger in the mine. The subject of ash in coal is dealt with more fully in the article on COKE. (See also Section III.)

Geological Formations in Which Coal Occurs.—Although by far the greater stores of coal and those of highest quality are contained in the great Carboniferous formation, and in particular in that part known as the Coal Measure series, yet the occurrence of coal is by no means limited to the carboniferous system. Eliminating lignite, which is chiefly a formation of Tertiary age, coal deposits are found as low down in the geological scale as the Silurian system, and in rocks as late as the Cretaceous age. Thus, the little coalfield of Brora in Sutherlandshire is of lower oolitic age. In Canada the coal of the Pacific Coast is of Cretaceous age. The coalfields of Cape Colony, the Transvaal and Natal are probably of Triassic origin. The coalfields of Russia were considered by Sir R. Murchison to belong to the Lower Carboniferous period, but others regard them as of Old Red Sandstone age. But in Great Britain the geological divisions which in this respect chiefly demand our notice are the Coal Measures, the Millstone Grit, and the Carboniferous Limestone Series, which together constitute the great carboniferous formation of Great Britain.

In England all the coalfields, with the exception of northern and western Northumberland, are in the Coal Measures. The British coalfields may conveniently be divided in the following manner:—

1. English Coalfields

The Great Northern Group.—Comprising the limestone coals, Northumberland and Durham coalfield and the Cumberland field.

The North Western Group.—Comprising the Lancashire and East Cheshire field, the Coalbrookdale (or Shropshire) field, and the Forest of Wyre field.

The North Midland Group.—Comprising the Yorkshire, Derbyshire and Nottinghamshire field.

The Midland Group.—Comprising the North and South Staffordshire coalfields, the Leicestershire field, and the Warwickshire field.

The Western Group.—Comprising the Bristol and Somersetshire fields and the Forest of Dean.

2. Welsh Coalfields

Comprising the South Wales field, the Denbighshire field, and the Flintshire field.

3. Scottish Coalfields

Comprising the Clyde basin, the Midlothian, the Haddingtonshire, the Fifeshire, the Ayrshire, the Lesmahagow and the Canobie fields.

4. Irish Coalfields

Comprising the northern and the southern group of detached coal areas.

Classification.—Frequent attempts have been made towards a scientific classification of coal, the broad division of anthracite, bituminous coal, and lignite and brown coal, not having been deemed sufficient. Perhaps the best is that adopted by the International Geological Congress held at Toronto in 1913. Coals were then divided into four main classes and three sub-classes, letters instead of names being used, and the fuel ratio taken as the basis of classification, thus,

$$\frac{\text{Fixed carbon}}{\text{Volatile matter}}$$

and, in the cases of B₁, D₁ and D₂, the split volatile ratio of

$$\frac{\text{Fixed carbon} + \text{volatile combustible}}{\text{Hygroscopic moisture} + \frac{1}{2} \text{ volatile combustible.}}$$

The classes were as follows:—

CLASS A

- (x) Burns with short blue flame; gives off 3 to 5% volatile combustible matter.

Fuel ratio 12 and over.

Calorific value 8,000 to 8,330 calories or 14,500 to 15,000 B.T.U.

Mean composition:—

Carbon 93 to 95%

Hydrogen 2 to 4%

Oxygen and nitrogen 3 to 5%

- (2) Burns with slightly luminous short flame and little smoke, does not coke and yields from 7 to 12% of volatile matter.

Fuel ratio 7 to 12.

Calorific value generally 8,300 to 8,600 calories or 15,000 to 15,500 B.T.U.

Mean composition:—

Carbon 90 to 93 %

Hydrogen 4 to 4.5 %

Oxygen and nitrogen 3 to 5.5 %

CLASS B

- (1) Burns with short luminous flame and yields 12 to 15% volatile matter; does not readily coke.

Fuel ratio 4 to 7.

Calorific value generally 8,400 to 8,900 or 15,200 to 16,000 B.T.U.

Mean composition:—

Carbon 80 to 90%

Hydrogen 4.5 to 5%

Oxygen and nitrogen 5.5 to 12%

- (2) Burns with luminous flame and yields from 12 to 26% volatile matter; generally cokes.

Calorific value 7,700 to 8,800 calories or 14,000 to 16,000 B.T.U.

Mean composition:—

Carbon 75 to 90 %

Hydrogen 4.5 to 5.5%

Oxygen and nitrogen 6 to 15 %

- (3) Burns freely with long flame; withstands weathering but fractures readily and occasionally has moisture content up to 6%; volatile matter up to 35%; makes porous, tender coke.

Fuel ratio (split volatile) 2.5 to 3.3.

Calorific value 6,600 to 7,800 calories or 12,000 to 14,000 B.T.U.

Mean composition:—

Carbon 70 to 80%

Hydrogen 4.5 to 6%

Oxygen and nitrogen 18 to 20%

CLASS C

Burns with long smoky flame and yields 30 to 40% volatile matter on distillation, leaving very porous coke.

Fracture generally resinous.

Calorific value 6,600 to 8,800 calories or 12,000 to 16,000 B.T.U.

CLASS D

Contains generally over 6% of moisture; disintegrates on drying; streak brown or yellow. Cleavage indistinct.

- (1) Moisture in fresh mined, commercial output, up to 20%.

Fracture: generally conchoidal.

Drying: cracks irregular, curved lines.

Colour: generally lustrous black, occasionally brown.

Fuel ratio (split volatile) 1.8 to 2.5.

Calorific value 5,500 to 7,200 calories or 10,000 to 13,000 B.T.U.

Average composition:—

Carbon 60 to 75 %

Hydrogen 6 to 6.5%

Oxygen and nitrogen 20 to 30 %

- (2) Moisture in commercial output over 20%.

Fracture: generally earthy and dull.

Drying: cracks generally separate along bedding planes and often show fibrous (woody) structure.

Colour: generally brown, sometimes black.

Calorific value 4,000 to 6,000 calories or 7,000 to 11,000 B.T.U.

Average composition:—

Carbon 45 to 65 %

Hydrogen 6 to 6.8%

Oxygen and nitrogen 30 to 45 %

This classification, giving names to the letters, may be interpreted thus:—

A₁ corresponds to anthracite.

A₂ corresponds to semi-anthracite.

B₁ corresponds to semi-bituminous coal (in this class would be included the so-called smokeless steam coal of South Wales).

B₂ corresponds to bituminous coal.

B₃ corresponds to bituminous coal of low fixed carbon content.

C corresponds to cannel coal.

D₁ corresponds to sub-bituminous coal or compact black lignite.

D₂ corresponds to lignite or brown coal.

Eliminating from consideration peats, brown coals, lignite and anthracite (see articles LIGNITE and ANTHRACITE), bituminous coal is divisible, for commercial purposes, into Gas, Coking, House, Manufacturing and Steam Coal.

Gas and Cannel Coals.—In the following two tables are given the analyses of some typical (British) gas and cannel coals. (See also article GAS MANUFACTURE.)

Composition of Gas Coals

| Colliery | Coalfield | Percentage composition | | | | | Percentage of coke | Yield of gas per ton of coal in cubic feet | Illuminating power in standard candles |

(1), (2), (4) *Modern Practice in Mining*. By R. A. S. Redmayne, vol. i, 1919.(5) to (9) *Supplement to Plotted Vertical Sections of Northumberland and Durham Coalfields*. By J. Kirsopp, 1902(3), (10) to (19) *Analyses of British Coals and Coke*. By Allan Greenwell and J. V. Elsdon, 1909.(20) *South African Engineering Journal*—Coal No., Dec. 1919, p. 87.

The cannel coals, which yield a great quantity of gas, differ in character from ordinary bituminous coals for they are dull pitchy to dark brown in appearance, break with a conchoidal fracture, are hard and dense, and devoid of coking properties. They are sometimes called "Parrot coals" because of their quality when heated of decrepitating with a crackling sound.

Coking Coal.—Certain bituminous coals under the application of heat possess the quality of intumescing, or coking, as it is termed (see *post.* Section III.). What determines the coking or caking property is not fully understood. It does not depend on the relative quantities of carbon and oxygen present, though coals rich in carbon and low in oxygen (*e.g.*, anthracite high in carbon content and low in oxygen), also coals comparatively low in carbon and high in oxygen content (lignite), do not cake. That physical conditions play some part in the coking property of coal would seem to be borne out by the fact that certain coals which do not readily coke, when ground fine enough and subjected to pressure do so. The principal requirement in respect of a *house coal* is that whilst it should produce a good bright fire it should not be too fierce, for which reason a steam coal and a furnace coal are not desirable. Owing to its intumescent quality a coking coal is also undesirable.

Manufacturing, Steam or Furnace Coals.—These should be capable of producing considerable heat, for which reason they should have a fairly high fixed carbon content but a low sulphur content. The most important characteristic of a steam coal is agreed to be inherent great heating power, and, whilst the fixed carbon content should be high, there should also be present a sufficient percentage of volatile hydrocarbons to permit of easy ignition and consumption of the fixed carbon. The ash content should be low, as being non-combustible it detracts from the calorific value of the fuel, and sulphur is detrimental as being destructive to the firebars. The coal should not be friable and should stack well. The tables on page 873 give the composition of some of the principal British steam coals.

Composition of Coal and Recent Scientific Research Thereon.—Coal being a complex colloidal organic substance of high molecular aggregation, requires for the elucidation of its chemical constitution the application of the best trained minds in organic chemistry, and although research work of late years has been greatly intensified in Great Britain, the United States, Germany, France and Canada, but little more has been discovered than was known at the commencement of the 20th century.

Chemists employ three experimental methods for the investigation of the coal substance: (A) thermal decomposition, (B) fractionation by a sequence or combination of solvents, and (C) oxidation of the coal, hydrogenation, halogenation, etc. The principal facts which have been established by these methods are:—

(A) M. J. Burgess and R. V. Wheeler (*Chem. Soc. Trans.*, vol. xcvi., 1910; vol. xcix., 1911; vol. cv., 1914) by thermal decomposition applied up to a temperature of 1100° C determined:—

(1) That the decomposition of the coal substance commenced about 350° C;

(2) That in respect of the coals examined, whether bituminous, semi-bituminous or anthracitic, there is a well-defined critical temperature between 700° C and 800° C which corresponds with a marked and rapid increase in the quantity of hydrogen evolved; and

(3) That the evolution of methane and other paraffin hydrocarbons almost entirely ceases at about 700° C.

They concluded that the coals examined by them contained two types of compounds of different degrees of stability, viz., the "resinic" or less stable, which on thermal decomposition yield principally paraffins and no hydrogen, and the "cellulosic" which yield principally hydrogen. The facts hold good, but the interpretation of them as given above is not universally accepted. For instance, H. C. Porter and G. B. Taylor, who have carried out researches on American coals (*Proc. Amer. Gas Inst.*, vol. ix. [1], 1914) repudiate the suggestion that the "resinic" constituents of coal would be less than the "cellulosic" and attribute the great increase in the evolution of hydrogen between 700° C and 800° C to secondary decomposition, and they found that more than two-thirds of the organic substance of coals is decomposable below 500° C. Their views about the composition of coal are best expressed in their own words:—

"All kinds of coal consist of cellulosic degradation products more or less altered by the process of ageing, together with derivatives of resinous substances, vegetable waxes, etc., in different proportions, more or less altered. They all undergo decomposition by a moderate degree of heat, some, however, decompose more rapidly than others at the lower temperature. The less altered cellulosic derivatives decompose more easily than the more altered derivatives, and also more easily than the resinous derivatives. The cellulosic derivatives decompose so as to yield H₂O, CO₂, CO and hydrocarbons, giving less of the first three products the more matured and altered they are. The resinous derivatives, on the other hand, decompose on moderate heating so as to yield principally the paraffin hydrocarbons, with probably hydrogen as a direct decomposition product. The more mature bituminous coals, having good coking properties, contain a large percentage of resinous derivatives and their cellulosic constituents have been highly altered. The younger bituminous or sub-bituminous coals are constituted of cellulosic derivatives much less altered than those in older coals. They undergo a large amount of decomposition below their fusion point, and possibly for that reason many of them do not coke."

Prof. W. A. Bone points out (*Soc. Chem. Ind.*, June 19, 1925) in his paper on the "Constitution of Coal," that in most recent coal research work little, if any, importance appears to have been attached to the nitrogenous constituents of coal, and there seems to be at least some room for doubt whether the supposed "resinic" constituents of coal have been rightly so called. He is inclined to think that our whole coal-nomenclature might be overhauled with advantage. Though there may be some doubt as to the feasibility of drawing a sharp line between the evolution of the various gaseous products in the case of a highly matured type of coal when under thermal decomposition, it is otherwise in the instance of an immature brown coal or lignite, as Bone's work has shown. The results being: (a) that up to a certain temperature (in the case of a dried sample of brown coal, from Morwell, near Melbourne, 375° C) the only gases expelled from the dried coal are steam and oxides of carbon, which evolution continues right up to (and perhaps beyond) 700° C; (b) that at a somewhat higher temperature range (in the case of the Morwell coal, 375°–500° C) methane and other hydrocarbons (without oxygen) appear; and (c) it is not until the temperature exceeds 500° C that hydrogen appears among the products.

(B) In 1899, Bedson discovered the solvent action of pyridine on coal, and much later, A. H. Clark and R. V. Wheeler (*Chem. Soc. Trans.*, vol. ciii., 1913) fractionated coal substance into three parts by first dissolving it with pyridine, then treating the pyridine extract with chloroform. The coal substance was divisible into: (1) that insoluble in pyridine, (2) that soluble in pyridine but insoluble in chloroform, (3) that soluble in both pyridine and chloroform. These fractions are frequently referred to as *alpha*, *beta* and *gamma* constituents respectively, as though they were distinct and definitely separate chemical substances, which is unfortunate seeing that they all contain carbon, hydrogen, nitrogen, oxygen and sulphur—in fact, nearly the same percentage of nitrogen and sulphur in each fraction. In the extraction of coal substances by benzene under pressure, Bone's work is of great interest. He employs benzene in a special form of extractor on the Soxhlet principle at pressures between 500 and 700 lb. per sq. in. and at temperature 260° to 285° C, and afterwards fractionates the extract by a suitable solvent treatment. He and his co-workers have by this means obtained four distinct benzene soluble fractions (*Proc. Roy. Soc.*, 105, Ser. A., 1924). This result is shown diagrammatically on the opposite page.

When working on a coking coal it was found that fractions 1 and 2 could be disregarded from the point of view of containing substances of a "binding" character. With regard to fraction 3, Prof. Bone says "the amount of this fraction was always very small, ranging between 0.3 and 0.8% only of the whole coal substances; so that, although it has good 'binding' properties, and therefore would be to some extent a contributory factor, it cannot be considered as the chief cause of the coking properties of the coals."

The substances contained in fraction 4 were different from the so-called "coal resins" and seemed to be rather of the "humic" type. Their chemical nature has not yet been finally established, but they constitute from 4.6 to 7.0% of the parent coal substance and have very pronounced "binding" properties, so that the rela-

| Concentrated Benzene Solution of Crude Extract Poured into Light petroleum (b. p. 40°-60°) | | | |
|--|---|--|---|

tive coking properties of bituminous coals run nearly parallel to their yields of this fraction. These may therefore be considered as the chief cause of the coking properties of coals.

F. Fischer, H. Broche, and J. Strauch (*Brennstoff-Chem.*, 1925) in an account of similar experiments made upon German bituminous coals some little time after the appearance of Bone's paper, divided their crude benzene extract into two fractions only, which probably explains the apparent discrepancy in interpretation of the results. The benzene extracts from a brown coal are chemically different from those yielded by sub-bituminous or bituminous coal. It would seem that the coking quality of a coal is the result of the maturing of coal and is a product of age, for in black lignite there is evidence of the incipient formation of substances closely resembling the coking constituent of the more mature coals.

(C) Recent chemical research on the character of coal includes the work of Dr. Bergius, the German chemist, during the period 1915-25. By subjecting coal to the influence of hydrogen under heat and pressure, he saturates the hydrocarbons in the coal, converting them and, it is claimed, some portion also of the fixed carbon, into saturated hydrocarbons, thus achieving the liquefaction of coal, the objective of chemists for many years. The process has not yet emerged from the laboratory stage, but should it prove a commercial possibility, the results on industry would be far-reaching indeed.

SECTION II: THE WORLD'S COAL RESERVES; OUTPUT, CONSUMPTION AND PRODUCTION COSTS

The International Geological congress which met in Toronto, Canada, in the year 1913, made an estimate of the world's resources of coal, for which purpose they took 1 ft. as the minimum workable thickness of seams, down to a depth of 4,000 ft. from the surface, and 2 ft. at depths of from 4,000-6,000 ft.—6,000 ft. being regarded by the Congress as the limit in respect of workable depth. The figures of the available resources which are given in millions of metric tons (a metric ton=2,204.6 lb.), are, in respect of continents as follows:—

World's Coal Reserves
(in millions of metric tons)

| Continent | Anthraxes including dry steam coals | Bituminous coal | Sub-bituminous coals, lignite or brown coals | Total in millions of metric tons |
|-------------------|-------------------------------------|-----------------|--|----------------------------------|
| Europe | 54,346 | 693,162 | 36,682 | 784,190 |
| Asia | 407,637 | 760,098 | 111,851 | 1,279,586 |
| Africa | 11,662 | 45,123 | 1,054 | 57,839 |
| America | 22,542 | 2,271,080 | 2,811,906 | 5,105,528 |
| Oceania | 659 | 133,481 | 36,270 | 170,410 |
| Total | 496,846 | 3,902,944 | 2,997,763 | 7,397,553 |

The great depth at which coal mining is carried on (4,000 ft. below the surface in Belgium) is surpassed by the still greater depth in the mining of mineral deposits (6,726 ft. in the St.

John del Rey mine in Brazil). The working of coal at great depths is, however, more difficult than the extraction of ore from a metalliferous vein at like depth, for whereas in the latter case the plane of the deposit is, as it were, usually on edge reaching to the surface, in the former case it is, usually, more or less flat, the whole of the coal being derived from, approximately, the same depth, and it is very doubtful whether it will ever prove commercially possible to produce coal from a depth greater than 5,000 feet.

On the question of supply, it is not so much the duration of the world's ultimate resources of coal that matters, but how long will the better and more cheaply-got coals last. European countries are rapidly exhausting their supplies of readily available coals, and, if the present relative rates of exhaustion are continued, the period of their complete exhaustion will arrive long before that of Asia and the New World.

In available resources of coal the American continent far exceeds the rest of the world; in North America there are 5,073,431,000,000 metric tons, and in South America 32,097,000,000 tons; of all individual countries the United States of America takes first place, her resources, for example, being considerably in excess of those of the whole of the British empire. At the present rate of output the North American resources, more especially those of the United States, will outlast all other countries, and will probably suffice for 2,000 years. Great Britain's supplies at the present rate of consumption will not suffice for more than 600 years at most, and if we take into consideration the coal existing to a depth of 4,000 ft. (the limit taken by the British royal commission on coal supplies of 1905) they will only last for 450 years. Germany, before the ceding to Poland after the World War of a part of her Silesian coalfield, and to France of her Saar and Lorraine fields, had resources of coal sufficient to last at the pre-War rate of output for 1,000 years, but much of her remaining coal is lignite, which is of much lower calorific value than true coal. France will have to live on imported coal much sooner than Great Britain or Belgium. The latter country has supplies sufficient for nearly 500 years. Switzerland could mine all her resources in a few years.

The most important of all classes of coal is that which is termed "bituminous," for not only does it provide the gas, coking, house and manufacturing, but many of the steam coals also. It is, too, from this class of coal that we obtain our coal derivatives, e.g., tar, pitch, sulphate of ammonia, paraffin hydrocarbons, benzene, toluene, dyes and some medicines. Curiously enough, the term "bituminous" was founded on a misapprehension but is a convenient one of which the use is almost a necessity from its having an almost universal currency among coal miners. Nothing analogous to bitumen exists in coals.

In view of the importance of the bituminous coals, it is fortunate that nearly 4,000,000,000,000 tons, or more than half of the world's coal reserves, are bituminous coal.

World Production.—The following statement shows, in comparative form, the production in long tons of coal by continents for 1913 and 1926:—

World's Coal Production

| Country | Production in long tons | |
|-------------------------|-------------------------|---------------|
| | 1913 | 1926 |
| North America | 531,600,000 | 607,660,000 |
| South America | 1,600,000 | 2,000,000 |
| Europe | 730,000,000 | 621,200,000 |
| Asia | 55,000,000 | 80,000,000 |
| Africa | 8,300,000 | 14,000,000 |
| Oceania | 15,000,000 | 16,450,000 |
| Entire world | 1,341,500,000 | 1,341,310,000 |

About 90% of the world's coal is derived from the coalfields of the United States of America and Europe, the aggregate output of the British Empire and the United States being respectively about one-quarter and one-half of the world's output. The annual output from the principal countries is shown in tabular form on the next page.

| | Year | Long tons |
|---|------|---------------|
| British Empire | | |
| Great Britain: | | |
| Anthracite | 1925 | 6,126,399 |
| Bituminous | 1925 | 237,049,842 |

| Japan: | | |
| Semi-anthracite | 1925 | 88,433 |
| Bituminous | 1925 | 30,865,385 |
| Brown coal | 1925 | 166,703 |
| Netherlands: | | |
| Bituminous | 1926 | 8,469,225 |
| Brown coal | 1926 | 207,800 |
| Poland: | | |
| Bituminous | 1926 | 35,064,562 |
| Brown coal | 1926 | 74,804 |
| Russia: | | |
| Bituminous: | | |
| European | 1926 | 20,000,000 |
| Asiatic | 1926 | 3,347,000 |
| Brown coal | 1926 | 1,000,000 |
| Spain: | | |
| Anthracite | 1926 | 381,931 |
| Bituminous | 1926 | 5,915,539 |
| Brown coal | 1926 | 482,199 |
| United States: | | |
| Anthracite | 1926 | 75,390,582 |
| Bituminous, including brown coal | 1926 | 516,330,000 |
| World total for 1926, long tons | | 1,341,310,000 |
| World total (estimated) for 1927 long tons | | 1,450,000,000 |

The following table gives for 1925-6-7 the production of (1) the British empire and (2) the rest of the world:—

*World's Production of Coal: 1925-27
(Including Brown Coal)*

| | 1925 | 1926 | 1927* |
|-----------------|---------------|---------------|---------------|
| British Empire | 306,000,000 | 193,000,000 | 320,000,000 |
| Other countries | 1,040,000,000 | 1,150,000,000 | 1,130,000,000 |
| Total | 1,350,000,000 | 1,340,000,000 | 1,450,000,000 |

*Estimated on data available.

The relative importance of the great coal-producing countries in point of coal production is illustrated diagrammatically in fig. 3. In regard to Great Britain, the average figures are taken and not those for the year 1926, as it was the year of the great national lock-out in the coal mining industry. In the case of the other countries named the figures are for the year 1926. In respect of Germany, the brown coal has been converted into terms of bituminous coal by dividing the output of brown coal by three.

FIG. 3.—DIAGRAM SHOWING RELATIVE OUTPUT OF THE WORLD'S GREAT COAL-PRODUCING COUNTRIES

production of coal was never greater than in 1926. (The great drop in production in respect of Great Britain was due to the national lockout in the coal mining industry.) A noticeable feature in the diagram is the upward grade in Germany's coal production; although she lost some of her coalfields, she has so developed her brown coal resources and increased the output from the remaining fields of true coal as to produce the remarkable result shown in this diagram. However, the brown coal on the curve of aggregate production has not been converted into terms of true coal. Coal is widely distributed throughout Germany, the principal field is that of the lower Rhine and Westphalia which centres in the industrial region of the basin of the Ruhr, a right hand tributary of the Rhine. In Saxony, Zwickau and Lugan are other important mining centres.

Production and Costs in Great Britain.—The following figure (fig. 5) shows in diagrammatic form the rapid increase in production in Great Britain during the last 100 years, a production necessitated by and conducive to a very great extension in industry, and to an increase of population from 11,090,120 in 1811, to 40,980,311 in 1911, the output of coal being estimated by the 1871 royal commission on coal supplies to have been 10,080,300 tons, or less than the production for one fortnight at the present time.

The production from the various British coalfields stated by counties was as follows for the year 1925¹:—

| England and Wales | Tons |
|--|-------------|
| Northumberland | 11,955,368 |
| Durham | 31,493,011 |
| Cumberland and Westmorland | 1,986,092 |

¹The figures for the year 1926 though available are not given as they are abnormal, that year being the year of the national lock-out of coal miners.

Scotland

| | |
|---|-------------|
| Fife and Clackmannan | 7,661,524 |
| Lothian | 4,253,079 |
| Lanarkshire: | |
| Anthracite | 559,845 |
| Other | 16,434,006 |
| Ayrshire, Dumfries and Argyll | 4,120,074 |
| | 33,028,528 |
| Total for Great Britain | 243,176,231 |

In 1913 Great Britain contributed 21.7% of the world's entire output of coal, and in the year there were 1,110,884 persons employed in about 3,000 coal mines, which were worked as about 1,500 separate undertakings. The coal properties, or royalties, as they are called in the industry, were vested in about 4,000 owners. Various estimates of the amount of capital invested in the coal mining industry have been attempted, that by Sir Josiah Stamp, £135,000,000, based on the output of five years preceding the war, being perhaps nearest the mark. It is agreed that of all the industries that contributed to the successful issue for the Allies of the World War, the coal industry was perhaps the most important.

The estimated cost of production and of profit to the coal owners in Great Britain arising from the sale of the coal prior to the war may be taken to have averaged as follows:—

| | s. | d. |
|---|----|----|
| Wages | 5 | 6 |
| Stores and pit wood | 1 | 0 |
| General expenses, inclusive of everything, except depreciation and interest | 1 | 3 |
| Total | 7 | 9 |
| Profit | 2 | 5 |
| Grand Total | 10 | 2 |

The average royalty rent payable to the owners of the coal averaged about 6d. per ton of coal raised.

Since the year 1923 the general tendency has been for coal in Great Britain to approach what for want of a better term may be called an economic basis of price (although it has not yet fallen to a pre-war level). This has been rendered possible by the decreased cost of production.

This is indicated by the following figures:—

Average of Four Quarters in Each Year in Shillings per Ton

| Period | Wages cost (per ton) | Total cost per ton including wages | Proceeds (per ton) |
|-----------------|-------------------------|---------------------------------------|-----------------------|
| | s. d. | s. d. | s. d. |
| 1922 | 12 2½ | 18 2½ | 19 1½ |
| 1923 | 12 4½ | 17 7½ | 19 9½ |
| 1924 | 13 3 | 18 7½ | 19 9 |
| 1925* | 12 6½ | 17** 11½ | 17 1 |
| | 11 7½ | 16† 10½ | |
| 1926† | 12 3½ | 17** 3½ | 15 8 |
| | 9 7½ | 14† 7 | |

*The subvention operated over the last two quarters of 1925.

†On the first of May, 1926, the production of coal was suspended. The figures given in the tables are up to the end of April, during which period the subvention was operative.

**Subvention included.

†Subvention excluded.

The cost of working at the end of June 1927 was 16s. 0.70d., and the average selling price of coal (proceeds of sales) 15s. 0.05d. per ton, or a loss of 1s. 0.65d. per ton. The earnings per man shift worked were 10s. 2.84d. and the output per man shift 20.47 cwt. (See also Section V.)

Production and Costs in the United States.—The output in the United States rose rapidly during the war years, attaining the enormous figure of 605,546,343 tons in 1918. After that it was subject to great variations, due principally to industrial unrest resulting in strikes of the miners; the production for 1925 being 522,474,999 tons. In 1926 the output amounted to 591,721,000 long tons, a number of colliers being on strike. But the productive capacity of the United States coal mines is far beyond the actual output.

In the United States coal is classified as "soft" coal (bituminous) and "hard" coal or anthracite. Great variation exists in quality in the different States and even in the same district, e.g., in Central Pennsylvania there are seams of semi-smokeless coals of high steaming quality; gas coals, coking coals, and in the west, coals of high volatile content which are sold as steam coals. So great, too, is the variation in the working conditions that, as in

FIG. 4.—CURVE OF ANNUAL OUTPUT OF COAL FOR THE WORLD AND THE THREE GREATEST COAL-PRODUCING COUNTRIES

the case of Great Britain, the problem of making an equitable wage scale to suit the varying conditions is extremely difficult. The output per man shift in the bituminous mines is just under 4 tons (year 1922 3.82 tons, year 1923 3.99 tons) and in the anthracite mines just under 2 tons (1923 1.97 tons and 1924 1.79 tons).

It is doubtful whether there are available positive figures of the cost of working all classes of coal in the United States calculated over the whole annual production, but it was possible to compare the returns for 1922 with those for 1916 in respect of 217 colliery owners in 31 fields and 11 States. From these concerns there were produced in the aggregate 66,000,000 tons in 1916 and 52,000,000 tons (of 2,000lb. per ton) in 1922, that is to say, 13½% and 12½% respectively of the total coal output of the United States. The working costs and sale prices per ton were as follows:—

| | 1916 s.d. | 1922 s.d. |
|--|--------------|--------------|
| Cost per ton (of 2,000lb.) f.o.b. | 4.8 | 10.5½ |
| | (\$1.12) | (\$2.51) |
| Labour cost per ton | 3.5½ | 7.7 |
| | (\$0.83) | (\$1.82) |
| Sale price per ton | 5.7½ | 12.4½ |
| | (\$1.35) | (\$2.97) |
| Percentage of labour to total cost | 74.1 | 72.5 |

The cost of coal to a consumer in America according to one qualified authority (H. F. Hopkiss, "Economics in Coal Mining in the United States of America," *Eng. Soc.*, W. Pa. 132-141; Dixon 141) is made up as follows:—

| | Per cent. |
|---|-----------|
| Purchase of coal, opening up mine, mining machinery, housing, | 8 |
| Mine supplies | 3 |
| Labour | 24 |
| Insurance and Taxes | 1 |
| Operators' profit | 3 |
| Railway Transport | 36 |
| Retailing | 25 |
| | 100 |

That is to say, 61% of the cost is absorbed in transport and retailing.

In America as in Great Britain, one of the great outstanding problems awaiting solution is that of distribution.

Production and Costs in Germany.—Like Great Britain, the year 1913 marked a record with 187,054,115 tons of "black" coal, or including brown coal, 272,885,210 tons, one ton of "black"

coal being equal to 2.8 tons of brown coal in point of heat value; and, when the brown coal is converted into briquettes, which is done to a considerable extent, to 1.4 tons of briquettes. Although her Saar and Lorraine coalfields passed to France in 1919, and part of her Upper Silesian field to Poland in 1922, yet Germany's output of "black" coal has suffered less than might have been expected. A heavy fall took place in 1922, due to "passive resistance" upon the occupation of the Ruhr by the Allies; recovery

FIG. 5.—DIAGRAM SHOWING THE OUTPUT OF COAL IN GREAT BRITAIN IN THE PERIOD 1660-1927 INCLUSIVE

set in later, the output for 1926 reaching to 143,027,000 tons, or, converting brown coal into terms of "black" coal, 189,081,333 tons.

Taking the whole of Germany and comparing pre-war and post-war results, the following figures show the relative outputs exclusive of brown coal:—

Output Per Man and Hours.—The following table shows the annual average quantity of coal in long tons raised per person employed under and above ground in the countries named:—

| Year | Great Britain | United States | Germany (c) (excluding brown coal) | France (d) |
|----------|---------------|---------------|---|---------------|
| 1910 . . | 256 | 618 | 242 | 192 |

The total home consumption of coal and lignite in Germany during 1924 was as follows:—

| | Tons |
|--|-------------|
| Coal from home sources | 118,828,644 |
| Lignite, home sources (converted $\frac{1}{3}$) | 41,453,276 |
| Plus imports | 160,281,920 |
| Less exports | 15,240,108 |
| Less reparations deliveries | 175,522,028 |
| Net consumption | 4,358,568 |
| | 171,163,460 |
| | 19,680,243 |
| | 151,483,217 |

Comparing the cost of working coal in *Great Britain* with the *Ruhr* district of Germany, the coal from which competes with British coal in the European and other markets, the following comparative figures were given in evidence before the 1925 royal commission on the coal mining industry (*see* evidence of Sir R. Redmayne):—

| | Great Britain quarter ending Sept. 30, 1925 | | | | | |
|----------------------------|--|------|------------------------|-------|----|-------|
| | With sub- vention | | Subvention deducted | | | |
| Cost of working per ton | s. | d. | s. | d. | s. | d. |
| Proceeds per ton | 17 | 7.57 | 17 | 11.64 | 15 | 1.50 |
| Loss per ton | 16 | 4.75 | 16 | 4.75 | 14 | 2.75 |
| | .. | 2.82 | 1 | 6.89 | .. | 10.75 |

output by the number of persons employed.

For comparative purposes as between countries, these figures are vitiated by the fact that the same number of days and hours may not have been worked in each country in respect of any given year; nor are the natural conditions with which the miner has to contend the same in each country. For instance, the conditions prevailing in the United States are perhaps the best in the world; on the average the seams are thick, with good roofs, and lying at shallow depths from the surface. In respect of the black coal of Germany, the conditions are somewhat more difficult than in Great Britain. Making the fairest comparison, namely, that of output per shift, calculated over all persons employed, that for Great Britain is at present about 17.85cwt. as against 19.5cwt. for the whole of the Ruhr coalfield. In the Ruhr field the rise in production per man per shift has been on the up grade. The output per shift in Germany of Lignite is very considerable, much of it being quarried "open-cast." In Great Britain the hours of work of the underground miner were in 1925 7hr., exclusive of winding time, say, on the average 7hr. 37min., but since then the length of the working shift has been extended at some collieries to 8hr. and at others to 7½ hours. In Germany (Ruhr) they are 8hr. inclusive of one winding time, so on the basis of the same length of winding time as in Great Britain the average time below ground is 8 hours. In France the working time is 8hr. inclusive of both winding times, so that miners actually work less time than in Great Britain. In the United States the time is 8hr. exclusive of both winding times, but as in the majority of the mines the

inlet is by way of adit or day-drift, the actual time below ground is probably on the average more than 8hr., though, from the report of the recent United States coal commission, the miners would appear to go into the mines and come out pretty well as they like.

SECTION III: UTILIZATION AND CONSERVATION OF COAL; ELECTRICAL POWER USES; COAL CARBONIZATION

The use to which a coal can be most profitably put depends on two factors, its chemical composition and its physical character. A coal may have a high fixed carbon content, and as such may be

FIG. 6.—CURVE SHOWING THE ANNUAL AVERAGE QUANTITY OF COAL RAISED PER PERSON EMPLOYED UNDER AND ABOVE GROUND IN GERMANY, THE UNITED KINGDOM AND THE UNITED STATES OF AMERICA

capable of giving out great heat, but owing to its low volatile hydrocarbon content prove useless as a steam-raising coal except under forced draught. Again the ash content in an otherwise perfect steam coal may be so high as to render it a costly coal to use; or its ash may be fusible at a comparatively low temperature, and so choke the firebars with clinkers; or the sulphur content may be so high as to prove a destructive element especially in the case of a water-tubular boiler; or a coal may be excellent in point of chemical analysis, but is so friable that it breaks up in transport and cannot be burnt except in a pulverized form for raising steam, and must be used for making coke, patent fuel, or as pulverized coal. But as to making coal into coke, all coals are not possessed of the caking property, a quality which probably depends on physical as well as chemical characteristics. (See Section I.)

Characteristics.—The most important class of coals is that commonly known as “bituminous” from their property of softening or undergoing an apparent fusion when heated to a temperature far below that at which actual combustion takes place. This term is founded on a misapprehension of the nature of the occurrence, since, although the softening takes place at a low temperature, still it marks the point at which destructive distillation commences and hydrocarbons, both of a solid and gaseous character, are formed. That nothing analogous to bitumen exists in coals is proved by the fact that the ordinary solvents for bituminous substances, such as bisulphide of carbon and benzol, have no effect upon them, as would be the case if they contained bitumen soluble in these reagents. The term is, however, a convenient one, and one the use of which is almost a necessity, from its having an almost universal currency among those connected with coal and coal mining.

Variations in composition are attended with corresponding dif-

ferences in qualities, which are distinguished by special names. Thus the semi-anthracitic coals of South Wales are known as “dry steam coals,” and when still less anthracitic are known simply as “steam coals,” being especially valuable for use in marine steam-boilers, as they burn more readily than anthracite and with a larger amount of flame, while giving out a great amount of heat, and practically without producing smoke. Coals richer in hydrogen, on the other hand, are more useful for burning in open fires,—smiths’ forges and furnaces,—where a long flame is required.

The excess of hydrogen in a coal above the amount necessary to combine with its oxygen to form water, is known as “disposable” hydrogen, and is a measure of the fitness of the coal for use in gas-making. This excess is greatest in what is known as cannel coal, the Lancashire kennel or candle coal, so named from the bright light it gives out when burning. This, although of very small value as fuel, commands a specially high price for gas-making. Cannel is more compact and duller than ordinary coal and can be wrought in the lathe and polished. These properties are most highly developed in the substance known as jet, which is a variety of cannel found in the lower oolitic strata of Yorkshire, and is almost entirely used for ornamental purposes, the whole quantity produced near Whitby, together with a further supply from Spain, being manufactured into articles of jewellery at that town.

By the term “ash” is understood the mineral matter remaining unconsumed after the complete combustion of the carbonaceous portion of a coal. According to Couriot (*Annales de la Société géologique de Belgique*, vol. xxiii, p. 105) the stratified character of the ash may be rendered apparent in an X-ray photograph of a piece of coal about an inch thick, when it appears in thin parallel bands, the combustible portion remaining transparent. It may also be rendered visible if a smooth block of free-burning coal is allowed to burn away quickly in an open fire, when the ash remains in thin grey or yellow bands on the surface of the block. The composition of the ashes of different coals is subject to considerable variation, as will be seen by the table below:—

Composition of the Ashes of Coals

| True coals | Silica | Alumina | Ferric oxide | Lime | Magnesia | Potash | Sulphuric acid | Phosphoric acid | Total |
|----------------------|--------|---------|--------------|-------|----------|--------|----------------|-----------------|--------|
| Dowlais, South Wales | 39.64 | 39.20 | 11.84 | 1.81 | 2.58 | .. | .. | 3.01 | 98.08 |
| Ebbw Vale | 53.00 | 35.01 | .. | 3.94 | 2.20 | .. | 4.89 | 0.88 | 99.92 |
| Königsgrube, Silesia | 55.41 | 18.95 | 16.06 | 3.21 | 1.87 | 2.05 | 1.73 | 0.36 | 99.64 |
| Ohio, U.S.A. | 44.60 | 41.10 | 7.40 | 3.61 | 1.28 | 1.82 | 0.59 | 0.29 | 100.69 |
| Lignites: | | | | | | | | | |
| Helmstadt, Saxony | 17.27 | 11.57 | 5.57 | 23.67 | 2.58 | 2.64 | 33.83 | .. | 97.13 |
| Edeleney, Hungary | 36.01 | 23.07 | 5.05 | 15.62 | 3.64 | 2.38 | 12.35 | .. | 98.12 |

The composition of the ash of true coal approximates to that of a fire-clay, allowance being made for lime, which may be present either as carbonate or sulphate, and for sulphuric acid. Sulphur is derived mainly from iron pyrites, which yield sulphates by combustion. An indication of the character of the ash of a coal is afforded by its colour, white ash coals generally being freer from sulphur than those containing iron pyrites, which yield a red ash. There are, however, several striking exceptions, as for instance in the anthracite from Peru, which contains more than 10% of sulphur, and yields but a very small percentage of a white ash. In this coal, as well as in the lignite of Tasmania, known as white coal or Tasmanite, the sulphur occurs in organic combination, but is so firmly held that it can only be very partially expelled, even by exposure to a very high and continued heating out of contact with the air. An anthracite occurring in connection with the old volcanic rocks of Arthur’s Seat, Edinburgh, which contains a large amount of sulphur in proportion to the ash, has been found to behave in a similar manner. Under ordinary condi-

tions, from $\frac{1}{8}$ to $\frac{1}{4}$ of the whole amount of sulphur in a coal is removed during combustion, the remaining $\frac{3}{8}$ to $\frac{7}{8}$ being found in the ash.

The amount of water present in freshly raised coals varies very considerably. It is generally largest in lignites, which may sometimes contain 30% or even more, while in the coals of the Coal Measures, it does not usually exceed from 5% to 10%. The loss in weight by exposure to the atmosphere from drying may be from $\frac{1}{2}$ to $\frac{3}{4}$ of the total amount of water contained.

When coal is heated to redness out of contact with the air, the more volatile constituents, water, hydrogen, oxygen and nitrogen, are in great part expelled, a portion of the carbon being also volatilized in the form of hydrocarbons and carbonic oxide, the greater part, however, remaining behind, together with all the mineral matter or ash, in the form of coke, or, as it is also called, "fixed carbon." The proportion of this residue is greatest in the more anthracitic or drier coals, but a more valuable product is yielded by those richer in hydrogen. Very important distinctions—those of caking or non-caking—are founded on the behaviour of coals when subjected to the process of coking. The former class undergo an incipient fusion or softening when heated, so that the fragments coalesce and yield a compact coke, while the latter (also called free-burning) preserve their form, producing a coke which is only serviceable when made from large pieces of coal, the smaller pieces being incoherent and of no value. The caking property is best developed in coals low in oxygen with 25 to 30% of volatile matters. As a matter of experience, it is found that caking coals lose that property when exposed to the action of the air for a lengthened period, or by heating to about 300° C, and that the dust or slack of non-caking coal may, in some instances, be converted into a coherent coke by exposing it suddenly to a very high temperature, or compressing it strongly before charging it into the oven. From the chemical point of view it might appear that the quantity of hydrogen is a governing factor in determining the coking ability of a coal, for an otherwise non-caking coal can be made to coke by adding to it a very small percentage of hydrogen. (See also COKE.)

Electrical Power Uses.—An important aspect of the coal question, especially for Great Britain, is not so much how long the coal reserves will last, as how long will the reserves of high-class and easily available coal last. In other words, how long will coal be available at a cost not relatively disadvantageous to her nearest competitors.

The report of the electricity sub-committee of the British coal conservation committee (1918) stated: "It is obvious that improvement in the commercial prosperity of a country—that is to say, the average purchasing power of the individual—depends on increasing the output per head. If wages be raised merely by increasing the selling price of the goods in the home market, there is no real advance, and to increase the selling price of the goods in the neutral and open markets of the world, is hardly possible in view of international competition. The only way to increase prosperity is to increase the net output per head of the workers employed."

In the United States of America the amount of power used per worker is 56% more than in the United Kingdom; and the best cure for low wages is more motive power. It has been settled conclusively of late years that the most economical means of applying power to industry is the electric motor, that is, as the means of applying the power which may have been generated by any form of prime mover (water, steam, gas or oil). In Great Britain the water power is negligible and the oil nil, so the problem resolves itself into the most economical production of electric power from coal.

It has been calculated from the data available in the British census of production, and making certain necessary adjustments, that—excluding the horse-power used at blast furnaces, gas-works, etc., since the coal consumed in these industries is excluded from the estimate of coal consumption in industry—the total capacity of engines, i.e., steam reciprocating, steam turbine, internal combustion, water power, and other power, in use was 10,024,996 h.p., of which—

| | | |
|-------|-------------------|----------------------|
| 91.2% | was in respect of | steam, |
| 6.4% | " " " " | internal combustion, |
| 1.7% | " " " " | water power, |
| 0.7% | " " " " | other power. |

It has been estimated, too (see report of the coal conservation committee), that were a complete system of electrification inaugurated in Great Britain, on the basis of the extent to which power is used at present, a saving of 55,000,000 tons of coal per annum might be effected, resulting in a saving of £27,500,000 (valuing the coal at only 10s. per ton), while if the coal were used for extended and new industrial purposes, some 15,000,000 h.p. would be continuously available for the purpose throughout the year.

This estimate is based upon the supposition that 7lb. of coal per horse-power hour is the present average consumption of coal in production of steam power (a figure which is certainly on the low side), which corresponds with 1.54lb. per h.p.-hour delivered at consumers terminals in the case of the Newcastle Electric Supply Co., perhaps the largest electric power concern in Great Britain in 1928.

Coal Carbonization.—Under the heading carbonization of coal must be included the gas industry, the coke industry, and the new industry which is springing up, namely, the low temperature carbonization of coal. In the first named the production of what is termed town gas is only part of the activities of the gas-maker. There are a number of by-products besides the residual coke, or "poor man's coal" as it used to be termed. During the war the resources of even the largest and best equipped gasworks were strained to the utmost to secure an increased output of benzene, naphtha, creosote and fuel oil. Another important by-product is sulphate of ammonia.

Gas-making, as well as the making of metallurgical coke, is a "high temperature carbonization" process with temperatures of 1,000° C or thereabouts, whereas in "low temperature carbonization" the temperature may range from 400° to 800° C. The results of low temperature carbonization as compared with high temperature carbonization are: a lower volume of gas but a higher yield of tar of lower specific gravity; a low yield of benzene and its homologues, but a large yield of the paraffin group, light fuel oils. The yield of ammonia compounds under low-temperature carbonization is usually negligible. Whereas the coke made under high-temperature conditions is difficult to burn under domestic conditions in Great Britain, being chiefly usable for metallurgical purposes; that yielded by low-temperature carbonization is an excellent household fuel containing as it does from 6 to 12% of volatile hydrocarbons. (See also Section VII. and the articles GAS MANUFACTURE; COKE; and LOW TEMPERATURE CARBONIZATION.)

Looked at from the point of view of coal conservation there can be no doubt that a large field of fruitful possibilities exists. The wasteful and harmful process of coking coal in beehive ovens, and of burning coal for power purposes and in the domestic hearth, processes whereby the gas and other by-products are dissipated into the atmosphere, results annually in an enormous loss of potential wealth, as well as injury to health and destruction of buildings and vegetation.

Once the leader in the manufacture of coke, there has been a failure in Great Britain to keep abreast of development in some other parts of the world in regard to constructional materials, types of ovens, size of battery, and cost of production. Where the coke produced is to be used at blast furnaces with steel works adjacent thereto, the coke oven plant will be most economically situated in close proximity to the latter, as there is then provided a source of demand for the waste gas in the steel works. If, however, a market exists for all the gas in the neighbourhood of the colliery for lighting purposes, then the case is reversed, and cost of transport of the coal to the steel works is saved.

In the United States of America the policy is to have the coke ovens adjoining the iron and steel works, and to have them in very large units. There are great advantages in having centralized coking establishments instead of many small and scattered units. A recent writer (R. Ray, B.Sc., F.C.S., *The British Coking Industry and Some of its Products*, Institute of Fuel, Nov. 1927), taking

COAL AND COAL MINING

FROM "COAL AGE" BY COURTESY OF THE MCGRAW-HILL PUBLISHING COMPANY

BITUMINOUS COAL MINING MACHINERY

1. Side view of loading machine showing gathering conveyor at right, swivel conveyor at left. This machine advances on track in the heading. The swivel conveyors, in front and rear of the machine, may be swung in any direction for gathering and loading the coal into mine cars
2. Caterpillar loader, at work in a heading, showing gathering mechanism, with conveyor and apron at right, swinging conveyor in the rear loading coal into cars
3. Shearing machine, cutting a vertical kerf in the face of the coal, thus lessening the quantity of explosive to be used in loosening the coal. This operation divides the room or heading face into large blocks to be blasted or "shot" before loading into the cars
4. Heading machine, driving a narrow place or entry without the use of powder. This machine cuts a vertical kerf on both sides of the entry, undercuts the coal forming another kerf, then punches down the coal to complete the entry
5. Loading machine, rear view. Loosened coal at right being gathered and loaded by conveyor to car at left. One operator using a loading machine does the work of many men shoveling the coal into mine cars by hand
6. Looking down conveyor heading towards the fan. The fabric air line, at right, ventilates the face of the heading, from which coal is being removed by shaking conveyor at left. This conveyor, loaded by one or more men, moves coal from face to train of cars at entry

a battery producing 270 tons a day and comparing it with one producing 1,300 tons, gives the costs per ton of the coke produced as 11s. 11.53d. and 6s. 1.27d., respectively.

The manner in which coal can be conserved in the processes of carbonization lies in the prevention of waste by recovering to the greatest extent possible the potential wealth in the coal. On the other hand, were the partially coked coal resulting from the low-temperature treatment of coal to be used for domestic heating instead of raw coal, the probability is that the consumption of coal for household purposes would be increased by one-third, on the basis that 20cwt. of raw coal will make 13cwt. of low-temperature coke.

Waste of Coal.—The other direction in which coal can be conserved is in the process of being mined, though the loss of coal in mining is not so great as is commonly supposed and not nearly as much as it was a century ago.

It used to be customary at one time—especially in some coalfields, South Wales for instance—to cast back the small coal into the goaf or waste, but very little is left underground at the present time (1928). Under 1% of the total coal gotten is left underground. The total approximate quantity of small coal cast back in the coalfields of Great Britain in the year 1917, as far as could be ascertained by the coal conservation committee, was 2,325,000 tons, of which 1,502,000 tons were attributable to South Wales. More extensive washing arrangements at collieries and in briquetting would conduce to the absorption of this loss in normal times, but at another time the difficulty may lie in marketing what coal is produced owing to the world depression in industry generally.

One source of loss—perhaps the greatest—is that in regard to the working of very thick seams lying at considerable depths from the surface. Under existing methods of working the so-called ten yard or thick coal of South Staffordshire (fully 10,000ac. of which lie at a depth of 400yd. and more from the surface, with an average thickness of 24ft., and approximately contain a quantity of available coal equal to at least 288,000,000 tons), the loss in working the seam at this depth has been estimated at 40% or 115,200,000 tons. But probably by a system of packing the wastes with spoil derived from the surface carried under hydraulic pressure, or even under compressed air pressure (the latter a process now being tried in Germany), this loss will become negligible.

Other sources of loss are those due to the spontaneous combustion of coal underground; from coal left in barriers; through coal left for support; through the drowning out of workings, and through having to leave “top” coal underground. The difficulties from spontaneous combustion are being overcome as the result of scientific enquiry. The loss through leaving top coal as being too poor in quality to work will be met by the creation of a market due to the advent of low-temperature carbonization and its use of coal in a pulverized form (*see article on PULVERIZED COAL*).

Of the quantity of “mineral” raised at the collieries of Great Britain, it is estimated that 2.9% is refuse, but from this refuse 4.7% is recovered in the form of coal.

The figures for the year 1917 were as follows:—

| | Tons |
|----------------------------|-------------------------------------|
| Gross output | 271,030,844 |
| Refuse | 8,046,935, or 2.9% of gross output. |
| Coal recovered from refuse | 381,598, or 4.7% of the refuse. |

There would appear to be room also for the introduction of methods of saving coal in the process of cleaning.

The consumption of fuel for the production of power at mines amounted in 1917 to nearly 17,000,000 tons, or 6.2% of the output. Under a system of the generation or transmission of electrical energy “in bulk,” with, consequentially, the most perfect means of fuel consumption, the probability is that the power necessary to work the collieries could be provided with a coal consumption of one-third that of the present amount, or result in a saving of about 10,000,000 tons of coal annually. It must be borne in mind, however, in this connection that the coal consumed in raising steam at collieries is frequently refuse and of such poor quality as to be difficult of disposal otherwise.

SECTION IV.: COAL MINERS: THEIR CHARACTERISTICS AND OCCUPATIONS

The coal miners of Great Britain, that is, those in employment at the mines, numbered 975,710 persons in 1927; and when the unemployed, the women and children and various surface workers are included, this figure likely exceeds 3,000,000. Differing greatly as between districts in point of disposition and dialect, they have three characteristics in common—independence, suspicion as to motive, and loyalty to their leaders. But whereas the Welsh miner is, owing to his Celtic temperament, impulsive, warm-hearted, imaginative and voluble, a good friend and a good hater, the miner of the northern coalfields is more stolid, slower to action and less easily reconcilable to altered conditions. This is instanced by the fact that, though the Welsh miner will come out on strike more readily than the northern miner, once the latter is on strike he will not so readily return to work as the Welshman. One of the qualities which coal miners share the world over is their helpfulness towards each other in times of distress.

In order to understand the miners one has to have regard to their history. Their characteristics are largely the outcome of their environment. Whereas the industries in which most other manual workers are engaged are of recent origin, coal mining is a very ancient occupation. Since—and probably before—King Henry III. granted to the goodmen of Newcastle-on-Tyne a licence to dig coals in the Castlegarth, there have been coal mines in Britain. In 1245 mention is made of the ways of persons employed in getting coal. In 1291 there is mention of the grant of a mine at Pittenerief in Fifeshire to the Abbey of Dumfermline; and coal was introduced into London in 1306.

Living in communities apart from other people, the miners have in the process of time acquired characteristics and a terminology peculiar to themselves. The nature of their work in the silence and dark of the mine conduces towards rumination. The long hours and arduous work have been preventative of leisure. Their sense of grievance has come down from the “bad old days” when women and young children—the latter of eight years and younger—were employed for 10 to 12 hrs. in degrading work below ground, and when “the colliers and salters of the North were bondmen, until 1775, when by Act 15 Geo. iii. C 28 their fetters were struck off” (Wade’s *History of the Middle and Working Classes*, p. 393). “They were in a state of slavery or bondage, bound to the collieries and salt works where they worked for life, and transferable with the collieries and salt works when their original masters had no further use for them” (Wade’s *British Chronology*, p. 530, 2nd ed. 1841). But all that is past and gone and is only here referred to as explanatory of much which is little understood in the coal miner of to-day.

Occupations.—In spite of the developments and improvements rendered possible in mines by the forward march of science, manual labour still plays a most important part in coal mining, and as much as from 60 to 70% of the cost of “getting” and delivering the coal into wagons is represented by workmen’s wages. The number of occupations covered by the terms coal miner, collier or pitman, which are synonymous, are much greater than is commonly supposed. Thus, taking the case of a large group of collieries in South Wales, the late Mr. Hugh Bramwell, when chairman of the South Wales Coal Owners’ Association, in giving evidence before the coal mining organization committee in Sept. 1915, showed the relative proportion of the different classes to be as follows:—

| | Per cent. |
|--|-----------|
| Underground Labour | |
| Colliers (i.e., men and boys employed in getting and filling coal at the face) | 36 |
| Repairers (engaged mostly in afternoons and nights) | 28 |
| Traffic men (hauliers, engine drivers, hutchers) | 18 |
| Officials (overmen and foremen) | 2 |
| Surface Labour | |
| Traffic and screening | 6 |
| Enginemmen and stokers | 2 |
| Mechanics | 3 |
| Foremen, clerks and weighers | 2 |
| Sundry labourers | 32 |

Underground labour at collieries comprises the following occupations, viz.:—

Hewers (known also as colliers, coalgetters, pitmen, pikemen or stallmen).

Shotfirers.

Putters (known also as hauliers, trammers or hurriers).

Shifters (known also as repairers, timberers, etc.).

Stonemen (known also as brushers, drifters, ridders, caunchmen).

Wastemen (workers in the return airways).

Drivers (known also as pony drivers, horse drivers).

Inclines workers (known also as ginney workers).

Helpers-up.

Rolley waymen (known also as mechanical haulage hands, wagon way men, road corporals).

Waterleaders.

Onsetters (known also as hutchers, hitchers-on, cage loaders).

Horsekeeper (known also as farrier).

Deputies (known also as deputy overmen, firemen, chargemen).

Overmen (known also as underlookers).

The proportion of coalgetters, *i.e.*, hewers or colliers, to the total of underground workers for all districts varies between 37 and 40%, *e.g.*, 1913, 40·8%, 1918, 37·7% (*see* report of coal industry commission, 1919).

In modern England the standard of living of the miner has been continually rising for a long time, as in other classes of labour. Taking the north of England as an example, the hewers' wages at the beginning of the 18th century were 1s. to 1s. 2d. per shift; at the beginning of the 19th century they had doubled, being 2s. 3d. to 2s. 6d. for a shift of 8 to 12 hrs. and in 1913, the last pre-World War year, they were 7s. to 8s. a shift of 7hr., in addition to which they had free house and coal, the value of which was not less than 1s. 8d. per shift. The chief impression left by an historical review of coal mining in the United Kingdom is the enormous progress made during the last two or three generations in every respect except the return on capital.

The United States of America is frequently quoted as offering a higher standard of living to employees than any Old World country, yet we find a high American authority (Edward T. Divine, *Coal* 1925) stating that the home conditions of the anthracite miners is very indifferent, the sanitary conditions are bad, nor does the standard of living correspond to the expectation created by the earnings. Of the bituminous coal miners the same is said to be true. In the "company towns," where many of the miners have to live, the author epitomizes the situation thus: "The general result is anything but a normal American community of free citizens."

SECTION V.: COAL MINING: THE ACTUAL OPERATIONS; COLLIERY OUTPUTS

The opening and laying out of a colliery is rarely undertaken without a preliminary examination of the character of the strata by means of borings, either for the purpose of determining the number and nature of the coal seams in new ground, or the position of the particular seam or seams which it is proposed to work in extensions of known coalfields.

Determination of Depth and Dip of Coal Seams.—The principle of proving a mineral field by boring, in the case where the true dip of the measure is known, is illustrated by fig. 7, which represents a line direct from the dip to the rise of the field, the inclination of the strata being one in eight, which is about 7° or 4·5in. to the yard. No. 1 bore is commenced at the dip, and reaches a seam of coal (A) at 40 fathoms, or 240ft. At this depth it is considered proper to remove nearer to the outcrop so that lower strata may be bored into at a less depth, and a second bore is commenced. To find the position of No. 2, so as to form a continuous section, it is necessary to reckon the inclination of the strata, which is 1 in 8; and as bore No. 1 was 40 fathoms in depth, we multiply the depth by the rate of inclination, $40 \times 8 = 320$ fathoms, or 1,920ft., which gives the point at which the coal seam (A) should reach the surface. But there is generally a certain depth of alluvial cover which requires to be

deducted, and which we call 3 fathoms, then, $40 - 3 = 37 \times 8 = 296$ fathoms; or, say, 296 fathoms is the distance that the second bore should be placed to the rise of the first, so as to have, for certain, the seam of coal (A) in clear connection with the seam of coal (B). In bore No. 3, where the seam (B), according to the same system, should have been found at or near the surface, another seam (C) is proved at a considerable depth, differing in character

FIG. 7.—PROVING COAL SEAMS BY BORE-HOLES

and thickness from either of the preceding. This derangement being carefully noted, another bore to the outcrop on the same principle is put down for the purpose of proving the seam (C); the nature of the strata at first is found to agree with the latter part of that bored through in No. 3, but immediately on crossing the dislocation seen in the figure it is changed and the deeper seam (D) is found.

The evidence therefore of these bores (3 and 4) indicates some material derangement, which is then proved by other bores, either towards the dip or the outcrop, according to the judgment of the borer, so as to ascertain the best position for sinking pits. (*See BORING.*)

Winning the Seam.—The working of coal may be conducted either by means of levels or galleries, known as adits, driven from the outcrop in a valley, or by shafts or pits sunk from the surface. In the early days of coal mining, open working or quarrying from the outcrop of the seams was practised to a considerable extent; but there are now few, if any, places in Great Britain where this can be done. (*See* article on ADIT.) In Great Britain, every coal mine has—unless exempted under certain conditions—to be provided with two shafts or outlets, affording separate means of ingress and egress, not less than 15 yd. apart, and having between them a communication of not less than 4ft. by 4ft.

The operations by which the coal is reached and laid out for removal are known as "winning," the actual "working" or extraction of the coal being termed "getting." A seam of coal is said to be won when the shafts reach it. The process of sinking the shafts is treated under a separate article to which the reader is referred. (*See* article SHAFT SINKING.)

Opening Out the Mine.—The shafts having been sunk and equipped, and the method of working having been decided upon, it is necessary to arrange for the lay-out, namely, the formation of the shaft inset, the size of the shaft pillars, the position of the shaft sidings, the making of the stables for the horses and ponies, and the number and position of the main roads.

The laying out of a colliery after the coal has been won, by sinkings or levels, may be accomplished in various ways, according to the nature of the coal, its thickness and dip, and the extent of ground to be worked. In parts of the South Staffordshire and other coalfields, where only shallow pits are required, a pair of pits may be sunk for a very few acres, while on the other hand where sinking is deep and consequently expensive, an area of some thousands of acres may be commanded from a couple of pits. In the latter case, which represents the most approved practice, the sinking is usually placed about the centre of the ground, so that the workings may radiate in every direction from the pit bottom with the view of employing the greatest number of hands to advantage. Where a large area cannot be commanded, it is best to sink to the lowest point of the field for the convenience of drawing the coal and for drainage of water. It is necessary to maintain a thick barrier of unwrought coal between the boundary of the mine and the workings of a neighbouring colliery, especially if the latter are to the rise. If a prominent line of fault crosses the area it may usually be a convenient division of the fields into sections or districts.

The first process in laying out the workings, if the seams are only moderately inclined, consists in driving levels in the coal seam from both sides of the shaft, which, having proceeded a sufficient distance, the "shaft pillars" are formed. These consist of large pillars of coal which are left unworked as a support to the shaft until the mine is worked out, when they are then worked off. (The arrangement of these pillars and of the main roads are illustrated in the article AIRWAY, to which the reader is referred.) This pillar is known in Scotland as the "pit bottom stoop." The junction of the levels with the pit is known as the "pit eye"; it is usually of an enlarged section, and lined with masonry or brick-work, so as to afford room for handling the trams (tubs, boxes, hutches) of coal brought from the working faces. In this portion of the pit are generally placed the hauling engine and the stables.

By the British Coal Mines Act of 1911 it is required that, in all mines opened after the commencement of that act, there shall be two main intakes—there are exemptions from this provision in certain exceptional and specified cases—of such size and maintained in such condition as to afford a ready means of ingress to and egress from the workings. Only one of these roads can be used for the haulage of coal. The distance from the downcast shaft, within which the two main intakes shall not be required to be provided, is the distance between the shaft and the edge of the shaft pillars (see fig. 8), and in the case of an inclined shaft or level entrance not driven in the coal seam, the distance shall be the distance between the point where the shaft or entrance strikes the seam and the edge of the pillar left to support the incline or entrance. If driven in the coal seam, the distance is 200yd. from the mouth of the entrance.

When the seams sunk to are highly inclined, they are won by driving from the shafts "cross-measure" or "level stone" drifts—or "cruts," as they are called in the steep or Rearer working (see next section) of North Staffordshire. This is shown in fig. 9, which is a section of shaft and the roads immediate thereto at Gelsenkirchen colliery, Westphalia, illustrating an arrangement of cross-measure drifts and subsidiary drifts, connecting the workings in highly inclined seams with the shafts. Fig. 10 is a section of a subsidiary drift at the same colliery.

The Bord and Pillar System of Working.—The removal of the coal after the roads have been driven may be effected in many ways, according to the custom of the district. All these may, however, be considered as modifications of two main systems, viz., the Bord and Pillar (or "stoop and room") and the Longwall.

In the Bord and Pillar system the field is divided into strips by numerous openings or excavations called "bords" (i.e., roads) driven at right angles to the main cleavage or "cleat," these openings being again divided by cutting through them at intervals with roads termed "walls" (which are parallel to the main cleavage or cleat), so as to leave a series of pillars arranged chequerwise over the entire area. The pillars are left for the support of the roof as the workings advance, so as to keep the mine open and free from waste. In the oldest form of this class of working, where the size of the pillar was about equal to the width of the "bord," from 50–70% of the whole seam was removed, the remainder being left in the pillars. Pillars are now made much larger than formerly; 22yd.×44yd., 44yd.×44yd., or even 44yd.×66yd. are frequent sizes, and the "bords" are made 5–6yd. wide, the "walls" 2 to 3 yards. (See BORD AND PILLAR.)

In the formation of the pillars (the first working, or working "in the whole" as it is technically termed) a much less percentage of coal is got than in the removal of the pillars (the second or "broken" working), and the coal is usually, unless the pillars are

crushed, smaller in size and the output per man less owing to blasting being generally necessary, especially if the coal seam be hard in character. If the pillars are too small or are irregularly removed, a "creep" is liable to set in, especially if the floor be soft; that is, the pillar will be forced into the floor owing to insufficiency of support offered to the superincumbent strata.

A coal seam with a soft pavement (floor, thill, spavin) and a hard roof present the conditions most favourable to "creep," the

FROM SIR R. REDMAYNE, "MODERN PRACTICE IN COAL MINING" (LONGMANS, GREEN & CO.)

FIG. 9.—SECTION OF SHAFT AND CROSS-MEASURE DRIFTS (CRUTS) AT GELSENKIRCHEN COLLIERY, WESTPHALIA, ILLUSTRATIVE OF A METHOD OF WORKING HIGHLY INCLINED SEAMS OF COAL

first indication of which is a dull hollow sound heard when treading on the pavement or floor, occasioned by some of the individual layers parting from each other as shown at (a) fig. 11; the succeeding stages of creep are shown at (b) (c) (d) (f) and (g) in the same figure; the last being the final stage, when the coal begins to sustain the pressure from the overlying strata, in common with the disturbed pavement.

"Thrusts" or "sits" are the reverse of creeps; in the one case the pavement is forced up, in the other the roof is forced or falls down for want of proper support, or tenacity in itself. This accident generally arises from an insufficient size of the pillars; some roofs, however, are so difficult to support that thrusts take place where the half of the coal is left in pillars. Fig. 12 will convey a general idea of the appearance of thrust—(k) (m) (n) showing different stages.

In the modern method of pillar working, as carried out in the Durham and Northumberland districts, the "bords" usually are from 5 to 6yd. wide, while the pillars are 22yd. broad and 30yd. long or larger, which are subsequently got out on coming back; or the "whole is followed up with the broken," that is to say, the pillars are removed contemporaneously with the projection of the "whole" workings, though well to the rear of them; a barrier of two or three ranges of pillars being left between the "working in the solid" or "whole," and the pillars which are being worked off. The space from which the entire quantity of coal has been removed is known in different districts as the "goaf," "gob" or "waste."

Modifications of the Bord and Pillar.—The modifications of Bord and Pillar working practised in Great Britain, and abroad also, are those known in Great Britain by the names of (1) Single and Double Stall, (2) Wide or Square work, and (3) Rearer workings. The first named is chiefly practised in South Wales, more particularly in the working of the anthracite seams and the "dry" steam coals, though even in the latter the Longwall method (see subsequent section) is adopted wherever practicable. The wide or square work is restricted to the working of the Thick or Ten Yard coal of South Staffordshire. The rearer working, which is a method of working highly inclined seams, is peculiar to North Staffordshire.

In the Stall working, or "bord and banks," as it is termed when practised in Yorkshire, where support is required to buildings, railways or reservoirs, the "stall" or "bord" is much wider, as well as

FIG. 8.—PLAN OF SHAFT SIDINGS SHOWING HAULAGE ENGINE, NAIL TRACKS, ROPES AND SHEAVES

the pillars or "banks," than in South Wales. In the South Wales case the levels are driven on the strike of the seam and out of these, at intervals of 15yd., stalls 5-6yd. wide at their full width are turned away and advanced on the full rise of the seam. When the stalls have attained their limit in length, a factor which will be governed largely by the character of the floor and roof, the pillars separating the stalls will be worked off. The "double entry" method of working in the United States of America is practically the same method.

In the case of Double Stall, the stalls are usually driven 10 yards in width, the dividing pillars being of like width. A road is kept up either side of the stall and maintained by a row of supports, the middle portion of the stall being filled more or less with débris, if such is available. On attaining its full length the separating pillars, or "ribs" as they are termed, are removed. The very thick and highly inclined seam in the anthracite region of Pennsylvania known as the "Mammoth" seam, which in some districts averages 60ft. in thickness and is known to have attained to roof., is worked by the Double Stall method.

Level tunnels are driven across the measures cutting the coal, slopes about 28ft. wide and 15ft. high are driven on the full dip of the seam. Out of these slopes level stone roads are turned away every 100yd. and the coal worked to the rise by means of "breasts," as the stalls are there termed (figs. 13 and 14). The level (a) is driven on the strike in the top of the seam, and an airway (b) above it. From the level two "chutes" (c) (c) are driven across the full width of the seam, being made 9ft. wide and 6ft. high, and at such an angle as will permit of the easy contact of the broken coal. The chutes are widened out on reaching the floor of the seam, the face of the coal being cut up to the top of the seam, as shown in the figure, and the breast advanced upwards. The distance between the chutes is about 30 feet. Through the pillar separating the stalls are driven the manways (d) with branches (e) (e) right and left connecting the two manways, which are supported by timber (fig. 15).

Perhaps the Wide or Square work as practised in South Staffordshire for getting the Thick or Ten Yard seam of that field is the method of working chiefly practised on an abnormally thick seam which is flat or of moderate inclination. Though it is probably one of the most wasteful of all methods now practised, and many modifications have been tried, it still proves the most effective method of working a seam under the peculiar conditions named.

The main roads having been driven out—in the lower part of the coal—to the boundary, and the branch or district roads turned away right and left and also driven to the boundary, the coal opened out by the latter is worked by dividing it into a number of large chambers termed in South Staffordshire "sides of work" (fig. 16). A side of work when completed will be 50yd. or more square, each chamber or "side of work" being separated from an "adjoining" side by a barrier of coal 8-10yd. wide, which is locally termed a "fire rib," the only openings between the chambers being those necessary for ventilation (see fig. 16). In forming a side of work the roof coal is cut down bed by bed according to the partings in the seam (for the thick coal of South Staffordshire consists of a series of closely associated coal seams, varying from 8 to 12 or 13ft., divided from each other by their partings, but making together one great bed from 15 to 36 or even in some cases 40ft. in thickness), small pillars being left for the support of the roof.

On the abandonment of a side of work the roads penetrating the barriers for the purposes of entry, ventilation and haulage, and known as "bolt holes," are dammed off so as to prevent risk of spontaneous combustion, to which this seam is very liable. Years after, when the roof has subsided and there are settled conditions of superincumbent strata, these abandoned sides of work

are re-entered and the pillars recovered as far as possible. There may be even a third working for the recovery of the barriers; so that, although in the first working not more than from 40-50% of the coal be recovered, ultimately over a period of years, the loss of coal may not exceed 10%. But the coal gotten in these later workings is frequently considerably crushed.

So far the workings subsequent to the first working have been confined to the "exposed" coalfield where the coal exists at shallow depths. The problem of recovery of the ribs and pillars when working at great depths in the "hidden" coalfield, where the coal measures are overlaid by the "Red" rocks as the Permian and Triassic systems are sometimes locally designated (e.g., at Baggeridge and Hamstead collieries, where, at the latter colliery, the coal lies in parts at a depth of over 700yd. from the surface), is as yet unsolved, for the crush will be very considerable.

FIG. 11.—ILLUSTRATING THE STAGES OF "CREEP" IN A COAL MINE

Not only are very thick seams more dangerous to work than thin seams by reason of the difficulties in the way of effective support of roofs and sides and from liability to spontaneous combustion, but the coal is gotten at a higher cost per ton than in the case of seams of moderate thickness, as for instance 5 to 7 feet. When thin seams or seams of moderate thickness are highly inclined, they are usually worked by the Reamer method or by the Longwall system, e.g., Bristol method, Scotch method or the Belgian and French methods, *tailles chassantes* or *tailles montantes*.

The Reamer method consists in laying out the mine in "panels" or districts of pillars to the rise from off the main roadways, which are driven on the "strike" or level course of the seam. The chief novelty of the system consists in the manner of working off the pillars which is commenced as soon as the panel reaches the barrier. The pillar is "entered up," that is, worked off in stages (or "shoulders," as the cuts are termed locally) in an upward direction, the angle of the workings being kept at about 45°. The coal falling into the level is drawn away and lowered down the incline, which constitutes the self-acting incline haulage road of the panel, on to the main level, along which it is hauled to the shaft. Scaffolding has to be erected to enable the miners to work and to protect them against falls, but ultimately, if the pillar being removed is below the goaf or gob, on breaking through into the goaf above it gradually fills up the excavated space and affords standing room for the coal hewer. The loss of coal in this method of working is very heavy by reason of crush and unrecoverable barriers and pillars. It has been estimated that not more than 60% of the available coal is recovered and raised to the surface.

Longwall System of Working.—The second great system of working is that known as Longwall or Long-work. This system or method of working, though it has been in operation at collieries for fully a century, and longer still in metal mines, has only within the last 50 years or so come into wide favour in coal mines. The coal is taken away either in broad faces from roads (gates, gateways or stalls), in some cases 10 to 11 but more commonly about 40-50yd. apart and parallel to each other, the essential feature being the removal of the whole of the coal at once, without first subdividing it into pillars to be taken away at a second working. The roof is temporarily supported by wooden props and by stone packs (walling) along either side of the gate roads, two or three yards in width, with intermediate pack walls in the goaf (gob or waste), if there is sufficient stone (dirt) to allow of their erection. The roof at the face is upheld by props, usually with "lids," i.e., short pieces of timber flat on the side against the roof.

The general character of a long-wall working is shown in fig. 17B, which represents an area of about 500ac. of hard steam coal. The principal road extends from the shafts southward; and on both sides of it the coal has been removed from the light-shaded area by cutting it back towards the boundaries, along faces about 50yd. in length, those nearest to the shaft being kept in advance of those farther away, producing a step-shaped outline to the face of the whole coal. It will be seen that by this method the whole

FROM SIR R. REDMAYNE, "MODERN PRACTICE IN COAL MINING" (LONGMANS, GREEN & CO.)
FIG. 10.—CROSS-SECTION OF A SUBSIDIARY DRIFT AT GELSENKIRCHEN COLLIERY, WESTPHALIA

of the seam, with the exception of the pillars which are sometimes left to protect the main roadways, is removed in one working. Where coal is left for the support of the main roads, it is recovered when the field has been worked to its boundaries, but more commonly the main roads are made in the goaf. The roads for drawing the coal from the working faces to the main haulage road are kept open by walling through the waste or goaf produced by the fall of the unsupported roof and are cut off at intervals by crossgates. The direction of the air current is shown by arrows, the return air passing from the face into the return airways to the up-cast shaft.

This is the method of working "Longwall forward," *i.e.*, taking the coal in advance from the pit towards the boundary, with roads kept open through the gob.

Another method consists in driving towards the boundary and taking the coal backward towards the shafts, or working homeward, or "retreating Longwall," as it is technically termed, allowing the waste to close up without roads having to be kept open through it. This is of course preferable in many cases, though not always, but is only applicable where the owner of the mine can afford to expend the capital required to reach the limit of the field, in excess of that necessary when the raising of coal proceeds *pari passu* with the extension of the main roads, and where he is prepared to go a long time without receiving any return on his capital.

The above is the method practised in working a thin seam of coal or a seam of moderate thickness, *i.e.*, from 1ft. 6in. to 7-8ft. in thickness, and that is flat or of moderate inclination. In Great Britain there are no very thick seams which are highly inclined; such thick seams as occur (*e.g.*, south Staffordshire) are practically flat. But in the coalfield of St. Etienne, there is one seam in particular which is very thick and highly inclined, the Grande Couche by name, which reaches to 80ft. in thickness, with an inclination varying from 30°-90° from the horizontal.

The method by which the seam is worked consists in driving levels along the "strike" or level course of the seam, one above the other, which are connected by inclines, and the coal between the levels is worked out by means of either horizontal or inclined slices. Cross-cuts or level holings are driven to the "hanging wall" and the "foot wall," out of which the slices or "lifts" are taken, and the coal worked off, the excavated part being tightly packed with stone. The workings of each sub-stage rest on the packing of the sub-stage below it, the sub-stages being worked in ascending order.

The coal concession is divided into "panels" or districts 130yd. wide and an inclined plane made in the middle of it, and one on either side from the bottom main level to the bottom of the first or top stage, the level in each sub-stage being turned away out of the middle incline and holed into the side or airway inclines, which secures the proper ventilation of the panel. It will be seen that the method is really a modification of the Longwall system.

The following instances of the Longwall system as applied to the working of thin seams or seams of moderate thickness where highly inclined, may be given as severally descriptive of the procedure in Scotland, Belgium and France respectively.

Scotland.—In the case under consideration, the seam is 2 ft. 4 in. thick, and its inclination from the horizontal 70°, the seam being won by cross-measure drifts driven out from the shafts to cut it. In the seam, levels are driven about every 30yd. and the coal worked off the side as in "overhead" stoping in the case of metaliferous mining, up to the level above, the coal falling down shoots, spaced 12yd. apart, into the level below. These shoots are about 3ft. sq. and are on the full rise of the seam and are "checked" (*see* fig. 17A) in order to break the fall of the coal. The men travel to the face by way of the shoots.

Belgium and France.—Very similar to that described above is the method of working coal on the Continent in thinnish seams when having a steep dip (*see* fig. 18). The cross-measure drifts (*étages*) which are usually driven from the shafts at distances

apart of 56 to 66yd., are about 10ft. wide by 9ft. high, the levels being driven in the seam right and left, one above the other, and connected by holings for ventilation purposes. The coal faces (*maintenages*), which are worked much in the manner of overhead stoping, are stepped and the worked coal passed down coal shoots as shown. When the seams are not so steeply inclined, *e.g.*, about 35°-40°, and are very thin, *i.e.*, under say 2ft. 6in. in thickness, the system of working adopted is that termed *tailles chassantes*, *i.e.*, Longwall worked on the level in contradistinction to *tailles montantes*, or Longwall worked to the rise, which is practised when the inclination is moderate, *e.g.*, 10° or under, this latter system being purely ordinary Longwall with a stepped face.

The distance between each cross-measure drift or main level (*étage*) is about 60 yd. so that a width of coal to that extent is won by each main level, which is divided by three coal levels 20 yds. apart, one to each step or stall, by which the coal is conveyed to the shoot which carries it to the main level. The line of advancement is on the level course, the coal-getters being protected from falling coal by slanting boards shown in plan, fig. 19.

Subsidence and the Packing of Goaves.—The filling or packing of the excavated spaces, in order to prevent or lessen the effects of subsidence of the overlying rocks, is a matter of importance in some cases. In France and Germany the method of filling the space left by the removal of the coal with waste rock, quarried underground or sent down from the surface, which was originally used in connection with the working of thick inclined seams by the method of horizontal slices, is now largely extended to Longwall workings on thin seams, and in Westphalia is made compulsory where workings extend below surface buildings, and safety pillars of unwrought coal are found to be insufficient. With careful packing it is estimated that the surface subsidence will not exceed 40% of the thickness of the seam removed, and will usually be considerably less. The material for filling may be the waste from workings or from the spoil banks at the surface; where there are blast furnaces in the neighbourhood, granulated slag mixed with earth affords excellent packing.

In a few anthracite collieries in America the small coal or culm and other waste are washed into the exhausted workings by water, which gives a compact mass filling the excavation when the water has drained away. A modification of this system is now largely employed elsewhere, *e.g.*, France, Westphalia and Sumatra, but hardly at all in Great Britain owing to its cost. In this method

FROM SIR R. REDMAYNE, "MODERN PRACTICE IN COAL MINING" (LONGMANS, GREEN & CO.)
FIGS. 13 AND 14.—ELEVATION (LEFT) AND PLAN (RIGHT) OF THE METHOD OF WORKING A THICK AND HIGHLY INCLINED SEAM, NAMELY, THE "MAMMOTH" SEAM, PENNSYLVANIA, U.S.A.

the filling material, preferably sand, is sent down from the surface through a vertical steel pipe mixed with sufficient water to allow it to flow freely through distributing pipes in the galleries commanding the excavations to be filled; these are closed at the bottom by screens of boards or brattice cloth, sufficiently close to retain the packing material, while allowing the water to pass by a lower level to the pumping-engine, which returns it to the surface. This is known as the "hydraulic" stowage of wastes. Where water is not available for the purpose, or cannot be used for other reasons, compressed air has recently been applied as

the propelling agent in some German mines.

Cutting and Propping.—The actual cutting of the coal is to a very great extent performed by manual labour, the tool employed being a sharp-pointed double-armed pick, which is nearly straight, except when required for use in hard rock, when the arms are made with an inclination or "anchored." The terms pike, pick, mandril and splitter are applied to the collier's pick in different districts, the men being known as pikemen or hewers. The

FROM SIR RICHARD REDMAYNE, "MODERN PRACTICE IN COAL MINING" (LONGMANS, GREEN & CO., LTD.)

FIG. 15.—PLAN OF A PORTION OF A MINE IN SOUTH STAFFORDSHIRE, ENGLAND, WORKED ON THE "WIDE" OR SQUARE LINK SYSTEM

most important operation in cutting coal is that known as holing or "kirving," which consists in undercutting the coal by means of a groove 12 or 14 in. wide at the face and sloping down to nothing at the far end, which is about 3-4 ft. in depth. So there is left an overhanging portion of coal, which, after the supports (sprags) that hold up the undercut coal are removed, either falls of its own accord or is brought down by wedging or blasting.

The process of holing in coal is one of the severest kinds of human labour. It has to be performed in a constrained position, and the miner sometimes lying on his side has to cut to a much greater height than is required to bring the coal down, in order to get room to carry the groove in to a sufficient depth, giving rise to waste in slack as compared with machine work. This is sometimes obviated by holing in a bed below, or even above, the coal, or in any portion of the seam of inferior quality, that may not be worth working, or in an interstratified band of dirt. The loss due to holing is proportionately greater in thin than in thick seams, the same quantity being cut to waste in either case.

The roof of the excavation is supported as the coal is removed, by packing up the waste material, and by a double row of props, placed at stated intervals apart along the face, the props of the back row alternating with those in front. The props used are of pinewood, large quantities of fir props being exported from the north of Europe and from France and to some extent Spain and Portugal, besides which some British pitwood is available, especially from Scotland. The quantity of imported foreign timber amounts to about 3,500,000 tons per annum. As the work proceeds the props are withdrawn and replaced in advance, except those that may be crushed by the pressure or buried by sudden falls of the roof.

In securing the roof and sides on roadways, malleable iron and steel are now used to some extent instead of timber. As a substitute for timber props at the face, pieces of steel joists, with the web cut out for a short distance on either end, with the flanges turned back to give a square bearing surface, have been introduced. In large levels steel girders are sometimes used to support the roof, but in the smaller levels complete arches made of pieces of rails fish-jointed at the crown are used occasionally. In another system, introduced by the Mannesmann Tube Co., the prop is made up of weldless steel tubes sliding telescopically one within the other, which are fixed at the right height by a screw clamp capable of carrying a load of 15-16 tons. These can be most advantageously used in thick seams 6-10 ft. or upwards.

When driving the roads in "whole" working in the Bord and Pillar system, it is usually necessary to cut vertical grooves in

the face at one side to determine the limit of the fall. This is known as "nicking." Where the coal is blasted down without "nicking" it is known as "shooting off the solid"; and where the coal is got without either "nicking" or "kirving," as "shooting out of the solid."

Mechanical Coal Cutters.—The substitution of mechanical contrivances for hand labour in cutting coal has been a favourite problem with inventors. As far back as 1761, one Michael Menzies of Newcastle-on-Tyne devised a machine for cutting coal which was worked by man and horse; but with the introduction of compressed air as a motive power in mines in 1855, a great impetus was given to machine cutters, and during the last 60 years great progress has been made. The writer of this article has particulars of the results obtained by a mechanical cutter at Elemore colliery in the county of Durham as far back as June and July 1865, and of Harrison and Frith's machines at Bishops Close colliery in the same county in Sept. 1865. Baird's machine, the "iron man" as it was locally termed, was one of the first machines applied. In March 1874 the cost of getting coal at Elemore Colliery by a mechanical cutter was 3s. 5d. per ton as against 3s. 4d. by hand, inclusive of cutting, putting and deputies, i.e. the total face cost of working. The machine employed was of the disc type and it was driven by compressed air.

Messrs. Gillot and Copley's (Barnsley) machine, also of the disc type, was working as far back as 1875 and had a great vogue for many years. It had two cylinders 7 in. dia. 12 in. stroke, driving a main shaft at a speed of 100 revolutions per minute. This shaft was connected by gearing with the cutting wheel or disc, fitted with 20 teeth on its outer circumference, which were alternately single and double. This disc, which was 3 ft. 10 in. dia. was placed horizontally, projecting from the bottom of the framework of the machine, and made six revolutions per minute. The machine under cut the coal to a depth of 3 ft. 4 in., the height of the cut being 4 inches. The machine was pulled along the face by a wire rope, one end of which was secured to the machine, the rope being carried along the face to a block fastened to a prop at the far end of the run, and returning to the machine was slowly coiled on a drum driven by the machine which ran on rails fixed in a thin iron sleeper. It was worked by compressed air, the pressure of which at the machine was 28 lb. per sq. in., and cut 70 yd. of face in four hours. The machine cost £200. It will be seen that this machine, which did not differ materially from present day machines of the disc type, performed excellent work.

Mechanical coal cutters can conveniently be divided into five classes, viz., disc, bar, chain, rotary heading and percussive cutters. The extent to which these cutters are respectively used in the coal-fields of Great Britain, and the quantity of coal cut thereby, is shown in the following table:—

Types of Mechanical Coal Cutters in Great Britain, and the Coal Cut by them (1925)*

| | Disc | Bar | Chain | Percussive and other machines | Total |
|------------------------------|------------|-----------|------------|-------------------------------|------------|
| Number of machines | 1,086 | 842 | 2,524 | 2,198 | 6,650 |
| Tons of coal cut in the year | 10,680,428 | 7,186,922 | 25,234,269 | 5,031,696 | 48,133,315 |

*Owing to 1926 being the year of the national lock-out, it is omitted from consideration.

Out of a total of 2,840 mines in Great Britain included under the Coal Mines Act (some few of which are Cleveland iron mines producing no coal), at only 915 coal mines are mechanical coal cutters used. In some coal mines they cannot be used as the coal will not stay up to be holed, and in others the nature of the roof is such as to necessitate close propping, so that there is not room for machines to move along the face. Of the machines, 3,134 are actuated by electricity and 3,516 by compressed air. About 20% of the national output of coal is got by mechanical coal cutters.

The construction of the disc type has already been described, the modern machines of this kind differing but little from the machines originally made by Gillot and Copley, but "skids" or "sledges" have largely taken the place of rails for the travel of the machine. (See fig. 20.) In order to keep the machine up to its work and counteract the outward thrust, when the machine is on skids, steel blades are attached to one side of the frame which cut into the floor. A disc machine cannot cut itself into the face, so it is necessary to provide a side for it to cut in from. These sides are termed "rooms" or "stables." Some of these machines cut in for a distance of five feet.

The Bar type (see figs. 21 and 22), consists of a bar, projecting from the frame of the machine, fitted with teeth, which is rotated by gearing. It is less powerful than the disc or the chain machine, but the bar, which is tapered to a point, makes a thicker cut and removes more material than the other two types of rotated cutters, and though a less powerful machine, it has these advantages over the other types, that it cannot be jammed by falling material; the bar is easily swung in and out of the cut; it cuts in either direction; "stables" are not required as it cuts itself into the face; "sprags" can be inserted close up to the cutting face. It is the most suitable machine for overcutting and deep cutting. (It has cut to a depth of 9 feet.) Its application is frequently well suited to cutting in a "band," if the latter is fairly thick. It has given good results in steeply inclined seams, and it is especially suited, as compared with the other rotating types, to working in a seam much dislocated by faults.

The Chain Machine (see fig. 23) consists mainly of a frame or "jib" 2 ft. in width, projecting from the main body of the machine and carrying an endless chain having cutting teeth. It is fitted with a single bevel-gear reduction from the motor to the cutting chain driving sprocket and with a worm-reduction and ratchet-gear drive to the haulage drum. It is mounted on skids, and is carried on them by adjusting screws. The machine is about 17 in. high, 2 ft. 0 in. broad and 7 ft. 9 in. long. The horse-power is 25-30.

Percussive or Reciprocating Machines (see fig. 29) have the advantage over the types already described in being lighter, more portable and much less costly. They are used, too, not only for under or over-cutting the coal horizontally, but for cutting in a vertical plane. The "Siskol" machine, which is of this type, is used chiefly for driving headings or for making "stables" for the disc and chain type to cut from, as well as for stone work. This machine has a cylinder of 3½ in. in diameter and works with an air pressure of from 50-80 lb. per sq. in., the extension rods being 20, 40, 60, 80 and 100 in. long. It is used in seams from 18 in. upward and is radial in its application. The machine is operated from a column by means of a sector and swings to and fro across the coalface. In the electric header the machine is rotary, whereas in the compression air machine the primary motion is percussive. Another type of percussive machine is the Ingersoll-Sergeant, which is directed and controlled almost entirely by hand.

Pneumatic Hammer Picks have come very largely into use of late years, especially abroad, many thousands being employed in the Westphalian collieries. The pick is used in Belgium also. This machine, which is only about 16-17 lb. in weight and about 17 in. long, with a piston 1½ in. dia. and 4½ in. stroke, is actuated by compressed air. The air is usually supplied from electrically driven compressors situated a little distance back from the coal face. A light sleeve valve placed in the axis of the small cylinder in a detachable head controls the distribution of the air, the admission ports being always closed before the opening of the exhaust ports, pressure of the air being from 60-80 lb. per sq. in. The pick makes 1,200 blows per minute and automatically stops when the workman ceases pressing on it.

Mechanical Conveyors.—The most economical way of working mechanical coal cutters is in conjunction with mechanical coal conveyors along the face in the case of Longwall, where the

FIG. 16.—PLAN OF TWO "SIDES OF WORK" WITH GATE ROADS, BOLT HOLES, FIRE RIBS AND PILLARS

conditions permit of these being placed and worked and in the gateways (roads) leading therefrom. There can be no doubt that the most economical way of transporting coal, from the point at which it is gotten to the shaft where the trams enter the cage, is to deliver the coal through the medium of face and gateway conveyors to the trams, and thence by means of small hauling engines actuated by electricity or compressed air (this is known as "secondary haulage"), and then to convey it to the main haulage planes along which the trams are conveyed to the shaft. Whereas in 1907 there were only 100 face conveyors in use in Great Britain, in 1926 there were 1,667.

Conveyors may be either (a) of the scraper continuous moving or (b) of the "shaker" (jigger or jerking) type. In the first-named class a series of scrapers carried by a chain pass along the surface of a steel trough, the chain being actuated by a small electric motor or compressed-air cylinder. The coal being filled into the trough is scraped along the trough to the tub (tram) in the gateway at the end of the stall or on to a gate conveyor. The conveyor being in sections is moved up as the face advances. The band conveyor is made up of solid woven cotton which passes over a drum. In the shaker conveyor the to-and-fro movement of from 6-12 in. is given to the trough, carried on rollers moving in curved paths, by means of an eccentric arrangement.

Underground Haulage.—The removal of the coal broken at the working face to the main haulage level is in the case of some small mines, especially in Somersetshire, effected by hand labour, but more generally it is done by pony, horse and mechanical traction upon tramways, the "trams" or "tubs," as the pit wagons are called, being brought up to the face. In steeply inclined seams passes or shoots leading to the main level below are sometimes used, and in Belgium and parts of Westphalia, iron plates are sometimes laid in the excavated ground to form a slide for the coal down to the loading place. As has just been stated, mechanically worked face conveyors are coming into use, which deliver the coal with a reduced amount of breakage, but this application is not as yet universal. The capacity of the trams generally speaking is determined by the height of the seam. From 6-10 cwt. are common capacities, but in South Wales they are larger, carrying up to one ton or more. The rails used are commonly of flat bottomed or bridge section varying in weight from 15-25 lb. to the yard; they are laid upon wooden cross sleepers in a temporary manner, so that they can be easily shifted along the working faces, but are more strongly secured along main roads intended to carry traffic continuously for some time. On the main haulage roads a heavier pattern of rail also is used, carried on chairs and fish-plated. In some main roads, when the distance to the pit is not considerable, horse traction may be used, a train of 6 to 15 vehicles being drawn by one horse, the "leading" of the trains of tubs may be effected by mechanical traction. In recent years,

FROM "REPORT OF THE ROYAL COMMISSION ON MINES, 1909," BY PERMISSION OF THE CONTROLLER OF H.M. STATIONERY OFFICE
FIG. 17A.—METHOD OF WORKING AN INCLINED SEAM IN SCOTLAND

objections to the use of animals underground have been advanced in many quarters.

In a large colliery where the shafts are situated near the centre of the field, and the workings extend on all sides, both to the dip and rise, the drawing roads for the coal may be of three different kinds, namely, (1) levels driven at right angles to the dip, suitable for horse roads, (2) rise ways, known as jinny roads, jigs, up-brows or inclines, which, when of sufficient slope, may be used as self-acting planes, i.e., the loaded trams may be made to pull back the empty ones towards the working faces, and (3) dip or down-brows, requiring engine power. A road may be used as a self-acting or gravitating incline when the gradient is about 1 in 10 or steeper. Where the load has to be hauled up a rising gradient, underground engines, driven by steam or compressed air or electric motors, are used, chiefly the latter. In some cases steam generated in boilers at the surface is carried in pipes to the engines below, but there is less loss of power when com-

pressed air is sent down in the same way and still less when electric power is employed. Underground boilers placed near the up-cast pit so that the smoke and gases help the ventilating furnace were in use to some extent in the past, but are now prohibited by section 56 (5) of the Coal Mines Act, 1911.

The principal methods in which power can be applied to underground traction are embraced in the following systems—

FIG. 17B.—THE LONGWALL SYSTEM OF WORKING

(1) main rope, (2) main and tail rope, (3) endless chain, (4) endless-rope system on the ground, (5) endless-rope system overhead, (6) overhead electric trolley wire, (7) electric and compressed air locomotives. Numbers 3, 4 and 5 may be considered as modifications of the same principle. In No. 1 a single line of rails is used, the empty tubs being run "in bye," by means of the force of gravity, and the loaded train or "set" of tubs is drawn up the acclivity by means of the same rope. The second method is applied where the inclination of the road is insufficient to allow of the gravitation "in bye" of the tubs, and they are drawn in by the "tail" rope being fastened to the inner end of the "set," while the loaded set is drawn out to the shaft by the "main" rope attached to the outer end of the set. In other systems, double lines with the rope travelling continuously in the same direction are the rule. When the set arrives "out-bye," the main rope will be wound up and the tail rope pass out from the drum to the end and back, *i.e.*, twice the length of the way; the set is returned "in bye" by reversing the engine. Considerable engine-power is required in order to get up the required speed, which is from 8-10 m. per hour. From 8-30 tubs are usually drawn in a "set," or train, the ways being often from 2,000-3,000 yd. long.

For the endless chain system, a double line of way is necessary, one line for full and the other for empty tubs. The tubs are placed on at intervals of about 20 yd., the chain moving continuously at a speed of from 2-3 m. per hour. This system presents great advantages in point of economy of driving power, especially where the gradients are variable, but is expensive in first cost and, though worked with branch roads, is not very well suited for curves, as a fresh set of pulleys worked by bevel gearing is required for each branch, the tubs disconnecting from the branch system and reconnecting with the main chain automatically.

In the endless-rope system the rope, which is guided upon sheaves between the rails, is taken twice round the head pulley. The tubs are placed singly on the rope or are formed into sets of from two to 12, the front one being coupled up by a short length of chain to a clamping hook formed of two jaws moulded to the curve of the rope, which are attached by the "run rider," as the driver accompanying the train is called. This system in many respects resembles the tail rope, but has the advantage of working with one-third less length of rope for the same length of way. The endless-rope system with overhead attachment is substantially similar to the endless chain.

Underground traction is performed in some cases, very largely

in America and Germany, electrically by the overhead trolley wire system, but in Great Britain the flashing that accompanies it is regarded as a danger and under the Electricity in Mines Rules the use of this means is prevented. Locomotives driven by compressed air were in use to a very small extent at one time in Great Britain, but their use was discontinued as uneconomic. The use of locomotives driven by power derived from electric storage batteries are coming into use in some few mines, being the most recent development in underground haulage.

Ventilation.—One of the most important branches of colliery work is the management of the ventilation, involving as it does the supply of fresh air to the men, horses and ponies working in the pit, as well as the removal of noxious and inflammable gases that may be given off in the mine. This is effected by carrying through the workings large volumes of air which are kept continually moving, descending from the surface by a shaft known as the down-cast shaft, and leaving the mine by a return or up-cast shaft. Such a circulation of air used to be obtained by means of an underground furnace, but under the Mines Act of 1911 no fire is allowed to be used for ventilation in any coal mine or seam newly opened after the passing of that act, except in the case of a mine in which the total number of persons employed below ground does not exceed 30 and in the up-cast shaft of which there is no inflammable material. In the mines where a fire is permitted and used for ventilation, the return air has to be carried off clear of the fire by means of a dumb drift, unless the mine is one in which inflammable gas is unknown.

Most mines are ventilated by means of fans. Mechanical ventilation may be effected, either by direct exhaustion or centrifugal displacement of the air to be removed, or by compressive ventilation forcing down the air. The former is the universal practice in Great Britain, but forcing ventilation is largely practised in the Continent of Europe. An early and very successful machine of this class, the Guibal fan, is represented in fig. 25. The fan has eight arms, framed together of wrought-iron bars, with diagonal struts, so as to obtain rigidity with comparative lightness, carrying flat close-boarded blades at their extremities. It revolves with the smallest possible clearance in a chamber of masonry, one of the side walls being perforated by a large round hole, through which the air from the mine is admitted to the centre of the fan. The lower quadrant of the casing is enlarged spirally, so as to leave a narrow rectangular opening at the bottom, through which the air is discharged into a chimney, or evase, of gradually increasing section carried to a height of about 25 feet. The size of the discharge aperture can be varied by means of a flexible wooden shutter sliding in a groove in a cast-iron plate, curved to the slope

FIG. 18.—METHOD OF WORKING VERY HIGHLY INCLINED SEAMS IN BELGIUM

of the casing. By the use of the spiral guide casing and the chimney, the velocity of the effluent air is gradually reduced up to the point of final discharge into the atmosphere, whereby a greater useful effect is realized than is the case when the air streams freely from the circumference with a velocity equal to that of the rotating fan. The power is applied by steam acting directly on a crank at the end of the axle, and the diameter of the fan may be 40 ft. or more.

Other types of fan are the Waddle, the Schiele (not now much used), the Walker (largely employed in Lancashire), the Chandler, the Capell, the Ser, the Rateau, the Sirocco and the Barclay. By the adoption of more refined methods of construction, especially in the shape of the intake and discharge passages for the air and the forms of the fan blades, the efficiency of the ventilating fan has been greatly increased, so that the dimensions can be much reduced and a higher rate of speed adopted. Another type is the double inlet Sirocco. These fans are made in a variety of sizes, from 2 ft. 11 in. to 8 ft. 4 in. diameter. It is a high velocity fan, and when 8 ft. 4 in. diameter, with double inlet and 220 revolutions per minute and a water gauge of 3 in., has drawn a volume of

air of 532,000 cu.ft. per minute through the mine.

Sir R. Redmayne applied a Parson's turbo-ventilator to ventilate a very deep mine. It was constructed to give 250,000 cu.ft. of air per minute against a water gauge of 12 in., the exhaustor being driven at a speed of 2,500 revolutions per minute.

The quantity of air required for a large colliery depends upon the number of persons and the number of animals employed, and the extent to which noxious and inflammable gas is evolved; also the extent to which it is necessary to cool the mine. Even with the best arrangements a dangerous increase in the amount of gas is not infrequent from the sudden release of large volumes stored up under pressure in the coal, which, overpowering the ventilation, produce magazines of explosive material ready for ignition when brought in contact with the flame of a lamp or the blast of a shot. The management of such places, therefore, requires the most constant vigilance on the part of the mine officials and workmen, especially in the examination of the working places that may have been standing empty during the night, or at other times, in which gas may have accumulated, to see that they are properly cleared before the place is occupied or a new shift recommences work, as well as during occupancy.

The actual conveyance of the air from the intake to the working faces is effected by splitting or dividing the current at different points in its course, so that each district of any size may be supplied with fresh air and have its own separate "intake" and "return" airways (*see* article AIRWAY), the current being carried as directly as possible to the coalface. In laying out the mine it is customary to drive the levels or roads in pairs, communication being made between them at intervals by cutting through the intermediate pillar; the air then passes along one and returns by the other, the air being kept up to the face by means of bratticing of canvas or wood, or air pipes and canvas doors. As the roads advance other pillars are driven through in the same manner, the passages first made being closed by stoppings of broken rock, or built up with brick and mortar walls, or both.

When it is desired to preserve a way from one road or similar class of working to another, double doors placed at sufficient intervals apart to take in one or more trams between them when closed are used, forming a kind of lock or sluice. These are made to shut air-tight against their frames, so as to prevent the air from taking a short cut back to the up-cast, while preserving free access between the different parts without following the whole round of the airways. It often happens that currents travelling in opposite directions are brought together at one point. In these cases it is necessary to cross them. The return air is usually made to pass over the intake by a curved drift carried some distance above in the solid measures, both ways being arched in brickwork. Or the sides of the intake are walled and the walls roofed over with dove-tailed timbers which constitutes the floor of the return air way. These are known as "air crossings."

The pressure required to overcome the friction offered by the rubbing surface of the galleries varies as the square of the velocity of the current, and the difference between the ventilating pressure as between intake and return airways is measured by the water gauge. The larger and more roomy the airways, the better for the ventilation, for the pressure per square foot necessary to overcome friction varies inversely as the sectional area of the roadway, the rubbing surface and the velocity remaining constant. Thus a roadway 9ft.x8ft. has a rubbing surface of 34 lineal ft. and a sectional area of 72ft., whereas a roadway of 13ft.x4ft. has a like rubbing surface, but a cross sectional area of 52 square feet. The same pressure would be required to draw the air through the one as in the case of the other.

Lighting.—The lighting of the underground workings in collieries is closely connected with the subject of ventilation, and in so far as safety lamps are concerned, is dealt with under the article of that name. In those mines where inflammable gas is

FROM SIR RICHARD REDMAYNE, "MODERN PRACTICE IN COAL MINING"

FIG. 19.—SYSTEM OF WORKING, KNOWN AS TAILLES CHANSANTES, IN A COLLIERY NEAR LIEGE

unknown, or occurs in the volume of air below the prescribed quantity, and in which no explosion of gas has occurred, open lights are frequently used, *e.g.*, the mines of the Forest of Dean and many of those in Scotland, where the lights take the form of the ordinary tallow dip candle or some kind of oil lamp—in Scotland usually carried in the hat. Usually the roads about the shaft bottom, and sometimes the way-ends of the several districts, are lit by electric lights.

Mine Gases.—The nature of the gases evolved by coal when freshly exposed to the atmosphere has been investigated by several chemists, notably by Lyon Playfair, Ernst von Meyer and Bedson. Von Meyer found the gases given off by coal from the district of Newcastle and Durham to contain carbonic acid, marsh gas (or light carburetted hydrogen, the "fire-damp" of the miner), oxygen and nitrogen (*see* article FIRE-DAMP). A later investigation by J. W. Thomas, of the gases dissolved or occluded in coals from the South Wales basin, shows them to vary considerably with the class of coal. The results given below, which are selected from a much larger series published in the *Journal of the Chemical Society*, were obtained by heating samples of the different coals *in vacuo* for several hours at the temperature of boiling water:—

| Quality | Colliery | Volume per ton in cu.ft. | Composition in volumes (per cent) | | | |
|------------|------------------|--------------------------|-----------------------------------|--------|-----------|----------|
| | | | Carbonic acid | Oxygen | Marsh gas | Nitrogen |
| Bituminous | Cwm Clydach | 19.72 | 5.44 | 1.05 | 63.76 | 29.75 |
| " | Lantwit | 14.34 | 9.43 | 2.25 | 31.95 | 56.34 |
| Steam | Navigation | 89.62 | 13.21 | 0.49 | 81.64 | 4.66 |
| Anthracite | Bonville's Court | 198.95 | 2.62 | .. | 93.13 | 4.25 |

Coal Dust.—The danger arising from the presence of coal dust in the air of dry mines, with or without the addition of fire-damp, has, since it was first pointed out by Prof. W. Galloway, been made the subject of special enquiries in the principal European countries interested in coal mining. The conclusions arrived at by the royal commission of 1891, which were, until recent years, taken as generally representative of the views of British colliery engineers, were as follows:—

- (1) The danger of explosion when gas exists in very small quantities is greatly increased by the presence of coal dust.
- (2) A gas explosion in a fiery mine may be intensified or indefinitely propagated by the dust raised by the explosion itself.
- (3) Coal dust alone, without any gas, may cause a dangerous explosion if ignited by a blown-out shot; but such cases are likely to be exceptional.
- (4) The inflammability of coal dust varies with different coals, but none can be said to be entirely free from risk.
- (5) There is no probability of a dangerous explosion being produced by the ignition of coal dust by a naked light or ordinary flame.

Since then, however, experiment and experience have shown that conclusions 3, 4 and 5 are not borne out in fact. A cloud of coal dust can be ignited by a naked light either through the medium of inflammable gas or not. The dusts of some anthracite mines would appear to be free from risk of explosion.

The important factors in connection with danger from coal dust would appear to be:—(a) the proportion of volatile hydrocarbons contained in the dust, (b) the purity of the dust, (c) fineness, (d) quality, (e) humidity.

The greater the proportion of volatile hydrocarbons the more easily ignitable is the dust, as also the freer it is from impurities such as stone dust, which exercises a deadening influence upon it. As to quantity, an explosion of coal dust has been obtained when only about 20z. of coal dust was present over an area of 10½ sq.ft. of surface. Humidity has a preventive or retarding effect on ignition.

It is laid down by Government regulations that in all coal mines in Great Britain, except those in which anthracite is worked, the floor, roof and sides (to within 10yd. of the coal face) of every road which is accessible, has either to be treated with incombustible dust so as to ensure that the dust on them shall always

contain not more than 50% of combustible matter, or to be treated with water so as to ensure that the dust thereon is always combined throughout with 30% by weight of water. But the percentage of incombustible dust required may be reduced by an amount equivalent to the percentage of water present in the mixture.

The incombustible dust has to be of such a character that not less than 50% of it must be capable when dry of passing through

BY COURTESY OF HAVOR AND COULSON, LTD.

FIG. 20.—SAMSON DISC COAL CUTTER DRIVEN BY DIRECT ELECTRIC CURRENT

a sieve with 200 meshes to the linear inch (40,000 to the sq.in.), unless a larger proportion of incombustible dust is used, when the percentage of fine material may be reduced to 25%.

Blasting and Explosives.—In all British coal mines when gas in dangerous quantities has appeared within three months, and in all places that are dry and dusty, blasting is prohibited, except with "permitted" explosives, whose composition and properties have been examined at the testing station at the Royal Arsenal, Woolwich. A list of those sanctioned is published by the Mines Department. They are mostly distinguished by special trade names, and are mainly of two classes—those containing ammonium nitrate and nitrobenzene or nitronaphthalene, and those containing nitroglycerin and nitrocellulose, which are essentially weak dynamites. The safety property attributed to them is due to the depression of the temperature of the flame or products of explosion to a point below that necessary to ignite fire-damp or coal dust in air from a blown-out shot. New explosives that are found to be satisfactory when tested are added to the list from time to time, the composition being stated in all cases.

Spontaneous Combustion in Coal Mines.—Underground fires are not uncommon accidents in coal mines. In the thick coal workings in South Staffordshire, the crusted coal in the sides of work is especially liable to fire from so-called spontaneous combustion, due to the rapid oxidation that is set up when finely divided coal is brought in contact with air; and not only that coal, but sometimes the solid coal also. The Bullhurst seam of North Staffordshire and some seams in Warwickshire, Lancashire and parts of Scotland are also liable to spontaneous combustion. The best remedy in such cases is to prevent the air from gaining access to the coal by building a wall round the burning portion, which can in this way be isolated from the remainder of the workings, and the fire prevented from spreading, even if it cannot be extinguished. When the coal is fired by the blast of an explosion it is often necessary to isolate the mine, or parts of the mine, completely by erecting dams, and in extreme cases by flooding with water or carbonic acid before the fire can be brought under. There have been several instances of this being done in the fiery pits in the Barnsley district, notably at the great explosion at the Oaks colliery in 1866, when 360 lives were lost.

Winding Coal in Shaft.—The drawing or winding of the coal from the pit bottom to the surface is one of the most im-

portant operations in coal mining, and probably the department in which mechanical appliances have been brought to the highest state of development.

The different elements making up the drawing arrangements of a colliery are (1) the cage, (2) the shaft or pit fittings, (3) the winding rope, (4) the engine and (5) the surface arrangements. The cage, as its name implies, consists of one or more platforms connected by an open framework of vertical bars of wrought iron or steel, with a top bar to which the drawing-rope is attached (*see article CAGE*).

The guides or conductors in the pit may be constructed of wood, in which case rectangular fir beams, about 3in. by 4in. are used. Two guides are required for each cage; they may be placed opposite to each other, either on the long or short sides, the latter being preferable. The cage is guided by shoes of wrought iron to cover the heads of the rails. Rigid guides connected with the walling of the pit are probably the best and safest, but they have the disadvantage of being liable to distortion, in case of the pit altering its form, owing to irregular movements of the ground, or other causes. Wooden guides being of considerable size, block up a certain portion of the area of the pit, and thus offer an impediment to the ventilation, especially in up-cast shafts, where the high temperature, when furnace ventilation is used, is also against their use. Wire rope guides have been introduced to a very considerable extent of recent years with a view of meeting the above objections. These are simply steel wire ropes, from $\frac{3}{4}$ –1½in. diameter, hanging from a cross-bar connected with the pit-head framing at the surface, and attached to a similar bar at the bottom, which are kept straight by a stretching weight of from 30cwt. to 4 tons attached to the lower bar. In some cases four guides are used—two to each of the long sides of the cage; but a more general arrangement is to have three—two on one side and the third in an intermediate position on the opposite side. Many colliery managers, however, prefer to have only two opposite guides.

The cage is connected with the drawing-rope, usually by six, but sometimes by four, short lengths of chain from the corners, and in the case of six chains, from the middle of the longer side also, known as "bridle chains," gathered into a central ring to which the rope is attached, through the medium of a socket or capel made of wrought iron larger at the bottom than at the top, and with a loop at the bottom through which the shackle of the detaching hook passes. Round steel wire-ropes about 2in. diameter are now commonly used, but in very deep pits they are sometimes tapered in section to reduce the dead weight lifted. Flat ropes of steel or iron wire are used but very rarely now, the round being generally preferred. In Belgium and the north of France flat ropes of aloë fibre (Manila hemp or plantain fibre) are in high repute, being considered preferable by many colliery managers to wire, in spite of their great weight. A rope of this class for a pit 1,200 metres deep, tapered from 15.6–9in. in breadth and from 2–1½in. in thickness, weighed 14.3 tons, and another at Anzin, intended to lift a gross load of 15 tons from 750 metres, is 22½in. broad and 3in. thick at the drum end, and weighs 18 tons. Tapered round ropes, although mechanically preferable, are not advantageous in practice, as the wear being greater at the cage end than on the drum it is necessary to cut off portions of the former at intervals. Ultimately also the ropes should be reversed in position, and this can only be done with a rope of uniform section.

Winding Engines.—The engines used for winding or hoisting in collieries when steam driven are usually direct-acting with a pair of horizontal cylinders coupled directly to the drum shaft. Steam at high pressure exhausting into the atmosphere is still commonly used, but the great power required for raising heavy loads from deep pits at high speeds has brought the question of fuel economy into prominence, and more economical types of the two-cylinder tandem compound class with high initial steam pressure, superheating and condensing are now applied to a large extent at modern collieries. One of the earliest examples was erected at Llanbradack in South Wales in 1894, and they have been extensively used in Westphalia and the north of France, as

well as in Great Britain. In a later example at the Bargold pit of the Powell Duffryn Steam Coal company a mixed arrangement is adopted with horizontal high-pressure and vertical low-pressure cylinders. This engine draws a net load of $5\frac{1}{2}$ tons of coal from a depth of 625 yd. in 45 sec., the gross weight of the four trams, cage and chains, and rope, with the coal, being 20 tons 12 cwt.

The work of the winding engine, being essentially of an intermittent character, can only be done with condensation when a central condenser keeping a constant vacuum is used, and even with this the rush of steam during winding may be a cause of disturbance. This difficulty may be overcome by using low-pressure turbines between the engine and the condenser. The accumulator, which is similar in principle to the thermal storage system of Dr. H. Halpin, is a closed vessel completely filled with water, which condenses the excess of steam during the winding period, and becoming superheated maintains the supply to the turbine when the main engine is standing. The power so developed is generally utilized in the production of electricity, for which there is an abundant use about large collieries.

The drum, when round ropes are used, is a plain broad cylinder with flanged rims, encased with soft wood packing, upon which the rope is coiled; the breadth is made sufficient to take the whole length of the rope at two laps. One drum is usually fixed to the shaft, while the other is loose, with a screw link or other means of coupling, in order to be able to adjust the two ropes to exactly the same length, so that one cage may be at the surface when the other is at the bottom, without having to pay out or take up any slack rope by the engine.

For flat ropes the drum consists of a solid disk, of the width of the rope fixed upon the shaft, with numerous parallel pairs of arms or horns, arranged radially on both sides, the space between being just sufficient to allow the rope to enter and coil regularly upon the preceding lap. This method has the advantage of equalizing the work of the engine throughout the journey, for when the load is greatest, with the full cage at the bottom and the whole length of rope out, the duty required in the first revolution of the engine is measured by the length of the smallest circumference while the assistance derived from gravitating action of the descending cage in the same period is equal to the weight of the falling mass through a height corresponding to the length of the largest lap, and so on, the speed being increased as the weight diminishes, and vice versa. The same thing can be effected in a more perfect manner by the use of spiral or scroll drums. This plan, though mechanically a very good one, has certain defects, especially in the possibility of danger resulting from the rope slipping sideways, if the grooves in the bed are not perfectly true. The great size and weight of such drums are also disadvantages, as giving rather unmanageable dimensions in a very deep pit. In some cases, therefore, a combined form is adopted, the body of

BY COURTESY OF MAVOR AND COULSON, LTD.

FIG. 21.—WORKING PARTS OF A BAR TYPE OF COAL CUTTER DRIVEN BY COMPRESSED AIR TURBINE

the drum being cylindrical, and a width equal to three or four laps conical on either side.

Counterbalance chains for the winding engines are used at some collieries. In Koepe's method the drum is replaced by a disc with a grooved rim for the rope, which passes from the top of one cage over the guide pulley, round the disk, and back over the second guide to the second cage, and a tail rope, passing round a pulley at the bottom of the shaft, connects the bottoms of the cages, so that the dead weight of cage, tubs and rope is completely counterbalanced at all positions of the cages, and the work of the engine is confined to the useful weight of coal raised. Motion is communicated to the rope by frictional contact with the drum, which is covered through about one-half of the circumference.

Winding is being performed at several collieries with electricity as the motive force.

The surface arrangements of a modern deep colliery are of considerable extent and complexity, the central feature being the headgear or pit frame carrying the winding rope pulleys, usually termed the "pulley wheels," which lead the winding ropes from the axis of the pit to the drum. This is an upright frame, usually

BY COURTESY OF MAVOR AND COULSON, LTD.

FIG. 22.—FRONT ELEVATION AND PLAN OF AN ELECTRICALLY DRIVEN BAR TYPE OF COAL CUTTER, CUTTING AT THE COAL FACE

made in wrought iron or steel struttled by diagonal thrust beams against the engine-house wall or other solid abutments, the height to the bearings of the guide pulleys being from 80 to 100 ft. or more above the ground level. This considerable height is necessary to obtain head-room for the cages, the landing platforms being usually placed at some considerable height above the natural surface, in order to provide height for the screens and wagons beneath the screening. The pulleys, which are made as large as possible up to 20 ft. in diameter to diminish the effect of bending strains in the rope by change in direction, have channelled cast-iron rims with wrought iron arms, a form combining rigidity with strength, in order to keep down their weight.

To prevent accidents from over-winding (which are, unhappily, not uncommon), when, in consequence of the engine not being stopped in time, the cage may be drawn up to the head-gear pulleys, various forms of hooks have been adopted. These consist essentially of links formed of a pair of parallel plates joined by a central bolt forming a scissors joint which is connected by chain links to the cage below and the winding-rope above. The outer sides of the link are shaped with projecting lugs above. When closed by the load the width is sufficient to allow it to enter a funnel-shaped guide on a cross-bar of the frame some distance above the bank level, but on reaching the narrower portion of the guide at the top the plates are forced apart, which releases the ropes and brings the lugs into contact with the top of the cross-bar, thus securing the cage from falling.

Three principal patterns, those of King, Ormerod and Walker, are in use, and they are generally efficient supposing the speed of the cage at arrival is not excessive. To guard against this, it is now customary to use some speed-checking appliance, independent of the engine-man, which reduces or entirely cuts off the steam supply when the cage arrives at a particular point near the surface, and applies the brake if the load is travelling too quickly. Maximum speed controllers in connection with the winding indicator, which do not allow the engine to exceed a fixed rate of speed, are also used in some cases, with recording indicators.

Unloading, Sizing and Cleaning the Coal.—When the cage arrives at the surface, or rather the platform forming the working top above the mouth of the pit, it is received upon the keeps or "keps," a pair of hinged gratings which are kept in an inclined position over the pit-top by counterbalance weights, so that they are pushed aside to allow the cage to pass upwards, but fall back and receive it when the engine is reversed. The tubs are then removed by the landers or "banksmen" (the men who put the tubs into the cage at the pit bottom being termed "onsetters"). These pull them forward on to the platform, which is covered with cast-iron plates; at the same time the empty tubs are pushed in from the opposite side. The cage is then lifted by the engine clear of the keeps, which are opened by a lever worked by hand, and the empty tubs start on the return trip. When the cage has several decks, it is necessary to repeat this operation for each, unless there is a special provision made for loading and discharging the tubs at different levels. An arrangement of this kind for shifting the load from a large cage at one operation is in use at many large collieries and is known as "simultaneous decking."

The trains are received into a framework with a number of platforms corresponding to those of the cage, carried on the head of a plunger movable by hydraulic pressure in a vertical cylinder. The empty tubs are carried by a corresponding arrangement on the opposite side. By this means the time of stoppage is reduced to a minimum.

Colliery Outputs.—In the United Kingdom the drawing of coal is generally confined to the day shift of eight hours. Some collieries produce very large outputs; at one colliery shaft in Yorkshire as much as 4,000 tons has been raised in one day. There are eight colliery concerns in Great Britain each raising 2,000,000 tons of coal or over per annum. The following interesting figures are given by the royal commission on the coal industry (1925), in respect of the outputs of 613 out of a total of 1,400 separate colliery undertakings in Great Britain.

Colliery Outputs

| Yearly output of undertaking in 1,000 tons | Number of undertakings | Total, in 1,000 tons | Percentage of total | Output per man per shift | Proceeds in shillings per ton | Cost: Shillings. per ton | Profit (+) or Loss (-) |
|--|------------------------|----------------------|---------------------|--------------------------|-------------------------------|--------------------------|------------------------|
| | | | | Cwt. | | | Per ton |
| Less than 5 | 10 | 32 | .. | 12.78 | 23.51 | 32.01 | -8.56 |
| 5 and under 200 | 307 | 27,360 | 12.7 | 16.22 | 19.02 | 20.23 | -1.21 |
| 200 " " 400 | 126 | 36,394 | 16.9 | 17.05 | 18.43 | 19.21 | -0.78 |
| 400 " " 600 | 72 | 35,118 | 16.3 | 18.34 | 17.90 | 18.01 | -0.14 |
| 600 " " 800 | 28 | 19,132 | 8.9 | 18.86 | 17.58 | 17.82 | -0.24 |
| 800 " " 1,000 | 20 | 17,992 | 8.4 | 18.68 | 17.52 | 17.65 | -0.13 |
| 1,000 " " 2,000 | 42 | 56,280 | 26.2 | 19.66 | 17.77 | 17.49 | +0.28 |
| 2,000 " over | 8 | 22,744 | 10.6 | 19.76 | 17.39 | 17.11 | +0.28 |
| All | 613 | 215,052 | 100.0 | 18.32 | 17.98 | 18.20 | -0.25 |

It will be seen that the figures as to cost per ton of production per man are favourable to the large as compared with the smaller concerns. (See also Section II.)

Preparation of Coal for the Market.—The tub when brought to the surface is passed over a weighbridge, where it is weighed by a weigher specially appointed for the purpose by the men and the owner jointly. It is then run into a "tippler," a cage turning about a horizontal axis, which discharges the load in the first half of the rotation and brings the tub back to the original position in the second, and is then run back to the pit-bank to be loaded into the cage at the return journey.

The coal after being raised from the pit is subjected to a process of classification and cleaning before being despatched to the consumer. The nature and extent of these operations vary with the character of the coal, which if hard and free from shale partings may be finished by simple screening into large and nut sizes and smaller slack and "duff"; the large being hand picked

to remove the shale. But when the coal is friable and there is much small, and it is dirty owing to intermixture of shale, more elaborate sizing, and cleaning by washing, becomes necessary. Where hand-picking is done, the larger sized coal, separated by bar screens at distances of 1½–3in. apart, is spread out on a travelling band, which may be 300ft. long and from 3–5ft. wide, and is there carried past a line of pickers who take out and remove

BY COURTESY OF MAVOR AND COULSON, LTD.

FIG. 23.—ARC WALL CHAIN CUTTER. WORKING AT 40 H.P. IT REQUIRES 750 CU.FT OF FREE AIR PER MINUTE

the waste as it passes by, leaving the clean coal on the belt. The smaller coal passing through the screen is carried by another belt to a separate sizing plant, consisting of vibrating and/or rotating screens, to be separated into several more sizes, e.g., trebles, doubles or single nuts, unscreened small, peas and beans, and duff (dust), trebles being over 1½in. diameter, doubles over ¾in., singles over ½in., etc. These are cleaned by washing in either continuous current or pulsating (jigging) machines, where the lighter coal rises to the surface and is removed by a stream of water, while the heavier waste falls and is discharged at a lower level or at the bottom of the machine. The cleaned coal is carried to a bucket elevator and delivered to the storage bunkers; or both water and coal may be lifted by a centrifugal pump into a large cylindrical tank, where the water drains away, leaving the coal sufficiently dry for use. Modern screening and washing plants, especially when the small coal forms a considerable proportion of the output, are large and costly erections, requiring machinery of a capacity of 100–300 tons per hour, which absorb 350–400h.p. In this, as in many other cases, electric motors supplied from a central station are now preferred to separate steam engines.

Anthracite coal is sometimes broken between toothed rollers where the smaller sizes are desired, and is in all cases subjected to an elaborate system of screening before it is fit for sale. The following are the classes, sizes, values and percentages of make of the several classes of market brands of anthracite at a large modern Welsh anthracite mine in 1927.

| | Class | Price | Per-centage | Size |
|------------------|----------------|-------|-------------|-------------|
| Hand picked | | s. d. | | Inches |
| | Large coal | 37 | 17 | Over 7 |
| | Cobbles | 41 | 7 | 2½ to 4 |
| | Washed cobbles | 17 | 2½ | 2½ to 4 |
| | French nuts | 41 | 7 | 1½x2½ |
| Washed | Stove nuts | 43 | 12½ | 1½x1½ |
| | Beans | 39 | 9 | 1½x1½ |
| | Peas | 18 6 | 11 | 1½x1½ |
| | Grains | 10 | 8½ | 1½x1½ |
| | Duff | 3 6 | 25 | ½ and under |

The number and variety of coal washers is considerable; the action of all is based upon the difference in the specific gravity of the three elements entering into consideration, namely, water with a specific gravity of 1, coal with a specific gravity of about 1.3, and shale with a specific gravity of about 2.3. In some "fine coal" washing machines a bed of felspar is provided, which having a specific gravity of 2.6 performs the function of a thick grating allowing of time for the particles of coal to be arrested and sent to the top. It gives a movable surface to the grating, so that every particle of the coal and shale is exposed to the action of the water.

Perhaps the most recent development in the cleaning of coal is that known as dry washing or dry cleaning. One such plant

used for cleaning nuts, where the use of water would cause discoloration of the coal and prove injurious to its marketing, is that made by the Meins Berrisford of Low Moor; the nut coal passes over an inclined glass plate which is kept clean by playing compressed air upon it. The coal passes over the glass but the dirt being heavier, falls down through a gap.

Depth of Working.—With the increased activity of working characteristic of modern coal mining, the depth of the mines has rapidly increased. The following list gives the depths reached in the deepest collieries in Europe in 1900, from which it will be seen that the larger number, as well as the deepest, are in Belgium:—

| | Feet |
|---|-------|
| La Providence, Belgium | 4,000 |
| Pendleton dip workings, Lancashire | 4,000 |
| work to a depth of 3,600ft. | |
| Sainte Henriette, Fleny, Belgium | 3,773 |
| Viviers Gilly, Belgium | 3,750 |
| Marcinelle No. 11. Charleroi, Belgium | 3,527 |
| Marchienne, No. 2 | 3,494 |
| Agrappe, Mons. | 3,478 |
| Sacré Madame, Charleroi | 3,461 |
| Ashton Moss dip workings, Lancashire | 3,360 |
| Ronchamp No. 11 pit, France | 3,330 |
| Astley Pit, Dukinfield dip workings, Cheshire | 3,150 |

The greatest depth attained in the Westphalian coal is at East Recklinghausen, where there are two shafts 841 metres (2,759ft.) deep.

The subject of the limiting depth of working has been very fully studied in Belgium by Prof. Simon Stassart of Mons ("Les Conditions d'exploitation à grande profondeur en Belgique," *Bulletin de la Société de l'Industrie minière*, 3 sér., vol. xiv.) who finds that no special difficulty has been met with in workings above 1,100 metres deep from increased temperature or atmospheric pressure. The extreme temperatures in the working faces at 1,150 metres were 79° and 86° F, and the maximum in the end of a drift, 100°; and these were quite bearable on account of the energetic ventilation maintained and the dryness of the air. The yield per man on the working faces was 4.5 tons, and for the whole of the working force underground, 0.846 ton, which is not less than that realized in shallower mines. From the experience of such workings, it is considered that 1,500 metres would be a possible workable depth, the rock temperature being 132°, and those of the intake and return galleries, 92° and 108° F respectively. Under such conditions work would be practically impossible except with very energetic ventilation and dry air.

Ownership of Coal.—In the United Kingdom the ownership of coal, like that of other minerals, is normally vested in the proprietor of the soil, and passes with it, except when specially reserved in the sale. Coal lying under the sea below low-water mark belongs to the Crown, and can only be worked upon payment of royalties, even when it is approached from shafts sunk upon land in private ownership. In the Forest of Dean, which is the property of the Crown as a royal forest, there are certain curious rights held by a portion of the inhabitants known as the Free Miners of the Forest, who are entitled to mine for coal and iron ore under leases known as "gales," granted by the principal agent or gaveler representing the Crown, in tracts not otherwise occupied. This is the only instance in Great Britain of the custom of free coal mining under a Government grant or concession, which is the rule in almost every country on the Continent of Europe.

The grantee of a "gale" makes a certain payment to the Crown and the whole area of the grant is within the control of the president of the Board of Agriculture. As a matter of fact, the free miners or "galees" in the majority of cases, sell their rights to the companies who work the coal, the others receive a royalty. This is an interesting case of workmen royalty owners.

SECTION VI: COAL MINING ACCIDENTS AND THEIR PREVENTION: THE RECORD OF CASUALTIES

The subject of health and safety in the mines of Great Britain is governed by the Coal Mines Act of 1911 and the regulations made thereunder, administered through the Mines Department of the Board of Trade. For the purpose of inspection, the country

is divided into eight divisions, each under a divisional inspector of mines, with a staff of both senior and junior inspectors under him, as well as several sub-inspectors of mines, a sub-inspector of quarries, and an inspector of horses. Over the whole inspectorate is the chief inspector with a deputy-chief and an electrical inspector of mines.

While there has been steady progress in the prevention of fatal accidents in mines in Great Britain during the last 50 to 60 years, coal mining is unfortunately a dangerous occupation, the number of fatal accidents averaging over 1,000 per annum in Britain. Thus:

| Decennial period or year | Death rate in Great Britain | |
|--------------------------|---|-----------------------------------|
| | Per 1,000 persons employed below and above ground | Per 1,000,000 tons of coal raised |
| 1873-1882 | 2.24 | 7.42 |
| 1883-1892 | 1.81 | 5.65 |
| 1893-1902 | 1.39 | 4.70 |
| 1903-1912 | 1.33 | 4.76 |
| 1913-1922 | 1.15 | 4.92 |
| 1913 | 1.55 | 5.81 |
| 1917 | 1.34 | 5.27 |
| 1918 | 1.39 | 5.86 |
| 1919 | 0.94 | 4.67 |
| 1920 | 0.88 | 4.60 |
| 1921 | 0.87 | 4.49 |
| 1922 | 0.95 | 4.32 |
| 1923 | 1.06 | 4.57 |
| 1924 | 0.98 | 4.36 |
| 1925 | 1.02 | 4.53 |
| 1926 | 1.08 | 4.95 |

For the purpose of the official returns made in Great Britain accidents are divisible under six heads, namely: (1) explosions of fire-damp and coal dust, (2) falls of ground, (3) shaft accidents, (4) underground haulage accidents, (5) miscellaneous underground, and (6) those occurring on the surface. The number of fatalities coming under the first division varies greatly, owing to the length of the periods separating great colliery disasters; the accidents under the other heads are not subject to the same variations. The chief cause of fatalities in mines, a class of accident not so spectacular as colliery explosions, but imposing a heavy and persistent toll on the lives of the miners, is that due to falls of ground. Thus, taking the years 1922 and 1925, the figures are as follows:—

| | 1922 | | 1925 | |
|-------------------------------------|--------|----------|--------|----------|
| | Killed | Injured* | Killed | Injured* |
| Explosions | 73 | 105 | 29 | 141 |
| Falls of ground | 551 | 63,035 | 559 | 60,454 |
| Shaft accidents | 39 | 971 | 37 | 1,255 |
| Haulage accidents | 211 | 46,839 | 260 | 43,771 |
| Miscellaneous underground | 125 | 59,254 | 164 | 58,851 |
| On surface | 999 | 170,204 | 1,049 | 164,472 |
| | 1,06 | 15,293 | 110 | 15,130 |
| | 1,105 | 185,497 | 1,159 | 179,602 |

*That is accidents disabling the persons injured for more than three days.

Falls of ground account for 50-55% of the accidents at mines, and haulage, *i.e.*, accidents due to the moving tubs and ropes underground, accounts for from 20-25%; so that three quarters of the accidents at coal mines in Great Britain are due to these two causes. Regarding the former, the chief inspector of mines of Great Britain comments in his annual report for the year 1926 as follows: "Falls of roof and side continue to account for more than half of the fatal accidents in mines. Innumerable pages have been written on this subject and innumerable suggestions made, but the progress made towards a lessening of the number can only be described as disappointing and disheartening."

Avoidable Accidents.—To what extent accidents in mines are avoidable or otherwise is a moot point. In a report written a

few years ago by the then chief inspector of mines, it was stated that all accidents had been classified to show whether they were avoidable or not, and so far as falls of ground were concerned about 72% were pronounced to be unavoidable, while as regards other accidents the percentage was 45.6.

Accidents from explosions are decreasing owing to our acquirement, during the last quarter of a century, of a greater knowledge

BY COURTESY OF THE INTERNATIONAL CHANNELLING MACHINES, LTD., SHEFFIELD

FIG. 24.—THE "SISKOL" PATENT ELECTRIC HEADING MACHINE

of the part played by coal dust, and the measures which have been adopted to combat the danger, e.g., prevention of accumulations, inter-mixture therewith of incombustible dusts, as well as the development of safety devices in connection with shot-firing, safety lamps, and in the application of electricity (see Section V.).

The question of support is now resolving itself into one of materials rather than of methods. Falls of ground on haulage roads might be reduced by the erection of steel arches to a larger extent than at present for the support of such roads. The chief inspector of mines in his annual report for the year 1926 stated: "In the South Wales Coalfield, where probably the greatest difficulties are experienced in keeping roads and faces open, steel arches for the support of roadways have been used for many years, and at present some of the collieries have over 20m. of roads so supported." Likewise, the benefits resulting from the use of steel props for the support of the working places is beginning to be realized. The first cost is greater than in the case of wooden props, but it is repaid many times over within a year or two.

But when all is said and done regarding means to be adopted for the reduction of accidents in mines, most is to be hoped from the "safety first" campaign which has been inaugurated at collieries. This is a process of intensive advertising by apt and pithy notices and illustrations of the dangers of carelessness and at some collieries the campaign is worked in conjunction with safety committees consisting of representatives of the officials and workmen, which are functioning admirably.

Coal miners are, on the whole, a strong and healthy body of men. The ailments to which they are most prone are chiefly nystagmus, neurasthenia, and, in the case of the older miners, respiratory diseases, such as bronchitis. Nevertheless, in spite of their dangerous occupation and liability to accidents, statistics show that miners live longer and enjoy better health than most men. (See also p. 198, Report of royal commission on the coal industry, 1925.)

In point of lowness of death rate from accidents in coal mines, Belgium stands best of all the great coal producing countries of the world, while the United States of America occupies the worst position. But between Great Britain, Belgium and France there

is very little difference. The mean annual death rate from accidents per 1,000 persons employed at coal mines in the principal coal producing countries of the world for the periods 1903-12, 1913-1922, 1923-1925, was as follows:—

| Country | Mean annual death rate per 1,000 persons employed | | |
|-------------------------------|---|---------|---------|
| | 1903-12 | 1913-22 | 1923-25 |
| Great Britain | 1.3 | 1.2 | 1.0 |
| France | 1.7 | 1.0 | 0.9 |
| Belgium | 1.0 | 1.2 | 1.1 |
| Germany: | | | |
| Prussian black coal mines . . | 2.1 | 2.8 | 2.2 |
| Union of South Africa | 3.5 | 2.4 | 2.7 |
| British India | 1.1 | 1.2 | 1.4 |
| Dominion of Canada | 3.4 | 4.4 | 2.7 |
| United States of America: | | | |
| Bituminous coal mines | 5.1 | 4.3 | 4.9 |
| Anthracite mines | 5.2 | 4.4 | 3.7 |

The higher rate obtaining in the United States of America is explained in the authoritative summary, by the staff of the United States coal commission appointed in 1922 as follows: "The higher accident rate per 1,000 employees and lower rate per ton of coal, obtaining in the United States, is due to the favourable natural conditions here for mining coal, the larger use of machinery, the high speed at which the industry works, and the venturesome spirit of the men in this and other American industries." As stated in *The case of Bituminous Coal* by W. H. Hamilton and Helen R. Wright (1925) "The high death rate is not due entirely to the natural hazards of the trade, which man is powerless to prevent. The Bureau of Mines estimates very conservatively that at least half of the annual deaths could be prevented." (See also United States Bureau of Mines, "Coal Mine Fatalities in the United States and Europe," by W. W. Adams, April 1924.)

SECTION VII.: LIGNITE: ITS PRODUCTION AND UTILIZATION

Lignite (see also Sections I. and II.) is the term commonly applied to immature coals, whether brown or black, or what American geologists term sub-bituminous coal. Properly speaking it comprises those solid fuels, young geologically, which have retained their wooden structure, and have the appearance of decayed wood (Lat. *lignis*, wood). The greater mass of the brown coal deposits of Germany, for instance, though commonly spoken of as lignite, has not a woody structure, though it contains occasional deposits of true lignite. Brown coal is probably a land formation, as is shown by the considerable number of tree trunks contained therein, and the deposits following naturally the cavities of the ground beneath the coal. Owing to the action of water and movements of glaciers, the deposits are sometimes interstratified with sand and clay.

Lignite is usually of Tertiary age. There is considerable variation in respect of its chemical composition, but two characteristics are fairly general, namely high moisture and volatile hydrocarbon content.

Prof. Elwood A. Moore gives the following as the composition of brown coal compiled from analyses of those coals derived from all parts of the world:

| | Variation % | Average % |
|---------------------------|----------------|-----------|
| Moisture | 0.75 to 43.00 | 14.42 |
| Volatile matter | 27.00 to 53.00 | 40.78 |
| Free carbon | 16.20 to 51.00 | 36.00 |
| Ash | 2.60 to 42.20 | 9.32 |
| Sulphur | 0.16 to 9.00 | 1.14 |

As a matter of fact, the moisture content is higher in some instances than that given above.

The world's available supplies of lignite (brown coal or sub-bituminous coal) were estimated by the Geological Congress held at Toronto in 1913 to amount to 2,997,763 million metric tons or about $\frac{1}{12}$ of the world's resources of fossil fuel. By continents

FIG. 25.—GUBIAL VENTILATING FAN

the supplies were estimated to be:—

| | Million metric tons |
|-------------------|---------------------|
| Europe | 36,682 |
| Asia | 111,851 |
| Africa | 1,054 |
| America | 2,811,906 |
| Oceania | 36,270 |

In the British Isles the deposits of brown coal are negligible; small deposits occur in Bovey Tracey in Devonshire and in County Antrim, Ireland. In Canada, Australia, New Zealand and India, the resources are, however, vast. In the United States of America there are also very extensive deposits of lignite.

The output of lignite and brown coal during the year 1924, as far as ascertainable, was 161,010,000 metric tons made up as follows:—

| | Metric tons |
|---|-------------|
| Germany | 124,360,000 |
| Czechoslovakia | 20,507,000 |
| Austria | 2,777,000 |
| Hungary | 5,429,000 |
| World's output, including small producers | 161,010,000 |

The greatest producer of brown coal is Germany. It is customary in Germany to differentiate as between those deposits of brown coal which are rich in bitumen and those which have a low bitumen content. The "bituminous" brown coal deposits are usually from 25–65ft. thick, whereas the "lean" seams often attain to a thickness of 330 feet. The German industry is highly developed and flourishing. Many of the deposits are "stript," or worked "opencast"; that is to say, where not too deeply buried, the overlying deposits of sand, clay and gravel are removed by excavators. It is regarded as a profitable proposition to remove the "overburden" up to a thickness of three times the thickness of the underlying brown coal deposit.

The chief consumption of German brown coal is the electric power industry, and whereas in 1913 brown coal was the source of only 23% of the electric power generated, in 1922 it had risen to 41·2%, the generation of electric power in Germany having more than trebled in that period, amounting in 1922 to 7,200,000,000 kw.-hours. With the concentration of electrical production in large works built within the last ten years, a saving of from 15–20% in coal has been effected.

The number of persons employed in producing the German output of 124,360,000 tons is about 134,140. The uses to which the fuel is put besides being consumed in its raw state for domestic and industrial purposes are, (1) in conversion into briquettes, (2) the extraction of montan wax, (3) carbonization and recovery of the light oils, (4) recovery of paraffin for candle manufacture.

Briquetting.—As the coal in its raw state contains about 50–52% of moisture it is first dried in steam heated driers down to 15% moisture, and then compressed by a steam actuated press, no binder being used, into briquettes of about 7in. long by 2½in. wide and 2in. deep with rounded ends. Formerly the use of brown coal briquettes was restricted almost entirely to domestic purposes, but latterly their use has extended to industrial and commercial undertakings. Generally speaking, the calorific value of the briquettes is double that of the raw brown coal. If the calorific value of German true coal (*steinkohle*) be taken in 7,000 calories, brown coal (*braunkohle*) at 2,500, and brown coal briquettes at 5,000 calories, then one ton of German true coal is equivalent to about 2·8 tons of brown coal or 1·4 tons of brown coal briquettes.

In 1923, 52,254,000 metric tons of raw brown coal were converted into briquettes (26,533,200 by the dry process and 3,209,000 by wet briquetting) in 239 works employing in all 35,902 workmen.

Extraction of Montan Wax.—When brown coal is treated with naphtha or benzol, "bitumen" is obtained in the form of montan wax. The commercial process consists in treating the dried coal in extracting cylinders with a mixture of hot benzol and alcohol, the extracting arrangements operating in the same way as the well known Saxhlet extractors in chemical laboratories. The benzol-alcohol is then evaporated and the montan wax recovered, the

recondensed benzol and alcohol being used over again. It does not pay to extract the montan wax unless the raw coal is rich enough therein to yield 10% of the substance on treatment in the laboratory by hot benzol.

There are not many deposits of brown coal in Germany sufficiently rich in "bitumen" to allow of the extraction of that substance in the form of montan wax. This substance, which in its refined state has the appearance of bees-wax, is used in the manufacture of boot polish, cable wax, special greases, lacquers, electrical insulation, gramophone records, light polishes, and as an addition to paraffin in the manufacture of candles. The price of raw montan wax averages £22 10s. per ton, the bleached wax fetching £87 10s.

The low temperature carbonization of lignite, and recovery of light oils and paraffin, is carried out in a retort known as the Rolle oven. It consists of a column of cast-iron circular collars superimposed one above the other, the column being enclosed in a fire brick erection. The coal passes down the narrow annular space between the column of collars and the enclosing firebrick cylinder which is heated by encircling flues, the gases distilled from the coal being drawn off through the collars and condensed in the ordinary way. The following figures are taken from actual results recently obtained at some carbonization works in western Germany:—

| |
|--|
| Through-put of coal containing 50% moisture, 3–4 tons per 24 hours, per oven. |
| Semi-coke made per oven per day, 1–1·5 tons or 33% of the raw coal. |
| Tar (60% of the possible yield as determined by analysis), 4–6% of the raw fuel. |
| Light oil stripped from the gas in proportion to tar, 16–20%. |
| Light oil per retort per day, 4·4 lb. |
| Consumption of brown coal for firing, 2%. |

In the year 1923, 14,056,000 tons of raw brown coal were subjected to distillation in 28 works employing in all 1,748 workers; 4,135,000 tons of semi-coke were obtained and 776,000 metric tons of tar.

SECTION VIII.: COAL: ITS SALE, DISTRIBUTION AND EXPORT.

An attempt was made by the British Coal Mining Organization committee in the year 1915 to arrive at some close approximation of the proportional distribution of the coal output of the United Kingdom, and in doing so they made a comparison as between the year 1903 and 1913, the object aimed at being to determine how the available supply could be distributed to meet the national requirements in the best possible way during the World War. The comparison was as follows:—

| Great Britain | 1903 | 1913 |
|---|-------------|-------------|
| | Tons | Tons |
| Total output | 230,334,469 | 287,430,473 |
| Reserved for home consumption (not including bunker coal for foreign trade) | 166,529,120 | 189,092,369 |

The balances were absorbed by export and bunkers.

The average pit-head value of a ton of coal in 1913, all kinds included, was about 10s. 2d. Of the home consumption it was estimated that at least 80,000,000 tons were absorbed in the production of power, inclusive of railways. The following table shows approximately the uses to which the coal was put:—

| Great Britain | 1903 | 1913 |
|--|------------|------------|
| | Tons | Tons |
| Railways | 13,000,000 | 15,000,000 |
| Coasting steamers (Bunkers) | 2,000,000 | 2,500,000 |
| Factories | 53,000,000 | 60,000,000 |
| Mines | 18,000,000 | 19,000,000 |
| Iron and steel industries | 28,000,000 | 31,000,000 |
| Other metals and minerals | 1,000,000 | 1,250,000 |
| Brick-works, potteries, glass-works and chemical works | 5,000,000 | 5,750,000 |
| Gasworks | 15,000,000 | 18,000,000 |
| Domestic | 32,000,000 | 35,000,000 |

The figures given for 1913, which are largely in the nature of an estimate only, will be fairly applicable at the present time.

The Export Trade of Great Britain.—Great Britain is the chief coal exporting country of the world, owing this pre-eminence largely to the variety and high quality of the coal produced, the accessibility of the coal, and the proximity of her coalfields to the sea, as well as to the fact that owing to her earlier industrialization than other countries, she was mining coal on an extensive scale before they had commenced to work their resources.

Although coal has been exported from Great Britain for six centuries, it was in an insignificant quantity until the 18th century, and the first accurate return of coal shipped is in 1791, when the total amount of coal shipped from British ports totalled 335,038 tons, the coal emanating chiefly from the great northern coalfield. By 1850, the exports of coal from Great Britain amounted to 11,000,000 tons; in 1890, 29,000,000; in 1900, 44,000,000 tons; and in 1913, 73,000,000 tons; or, adding the quantity supplied as bunkers to vessels engaged in the foreign trade, the coal equivalent of the coke, and the patent fuel (briquettes) exported, more than 98,000,000 tons, or 34% of the total output, was shipped.

Great Britain still retains the advantage of owning the higher quality and greatest variety of coal as compared with any other country. Her collieries are in the great majority of cases closer to the sea than is common in other countries, and cheap freights are still available; but the production of coal in other coal-owning countries has increased enormously, and not only are their demands in respect of imported coal less than formerly, but in some cases they have become rival competitors for the available export markets.

In fig. 26 the extent of the exports of coal from the United Kingdom is shown diagrammatically in comparison with the exports from Germany and the United States, 1910 to 1926.

The table below shows the export trade in coal of the three great coal producing countries in 1913 and 1924, compiled from the coal tables (1924) issued by the British Mines Department.

World's Coal Export Trade (in millions of long tons), including coal shipped as bunkers by vessels engaged in overseas trade, and also coal equivalents of brown coal, coke and briquettes.

| Country | Quantity | | Per cent of total | |
|---|----------|-------|-------------------|-------|
| | 1913 | 1924 | 1913 | 1924 |
| Great Britain | 98.3 | 82.0 | 49.8 | 51.2 |
| Germany, including reparation deliveries* | 47.4 | 25.1 | 24.0 | 15.6 |
| United States | 23.6 | 19.8 | 12.0 | 12.4 |
| Total of above | 169.3 | 126.9 | 85.8 | 79.2 |
| The World | 197.3 | 160.2 | 100.0 | 100.0 |

*Coal equivalent of brown coal briquettes delivered on reparation account is included here.

These figures show that Great Britain had improved her position in point of her percentage of the world's coal export trade, but inasmuch as the total amount of coal exported from all countries had declined, the weight of coal exported by Great Britain had also declined. The year 1925 showed a further decline of nearly 11,000,000 tons in respect of British coal exports, and, as the figures show, the exports for 1926 were very seriously affected by the lock-out, which caused the exports, including bunker coal shipped in vessels engaged in overseas trade, to be only 28,184,165 tons. Since the end of the last century, the competition of foreign coal has confined all increase in demand for British coal to markets situated, as was pointed out by the late Lord Rhondda, "within a portion of the globe limited by the Suez Canal on the east, by a line drawn from Cape Horn to the Cape of Good Hope on the south, and by a line from Cape Farewell to, say, Trinidad on the west." In 1873 one-fifth of the coal exported from Britain was shipped to regions beyond Europe and the Mediterranean; in 1913 the proportion was only one-eighth.

Taking the whole of the British Coal exports as 100, and dividing the world's markets into nine groups, the proportions of coal

exported thereto in 1913 and 1924 respectively were as follows:—

| Group | Year | |
|---|------|------|
| | 1913 | 1924 |
| | % | % |
| I. Russia, Poland and Scandinavia. | 21.7 | 17.1 |
| II. Germany, Netherlands, Belgium, France and Switzerland | 35.3 | 46.9 |
| III. Spain, Portugal, Italy, Malta, Gibraltar and North Africa (except Egypt) | 21.7 | 19.5 |
| IV. Austria-Hungary, Balkan States, Turkey (European and Asiatic) and Egypt | 7.7 | 4.8 |
| V. West Coast of Africa, Azores, etc. | 2.4 | 2.0 |
| VI. East Coast of Africa, Union of South Africa, Madagascar, etc. | 0.3 | 0.2 |
| VII. Arabia, Indian Ocean and Continent, Malaya, Oceania and Further Asia | 1.1 | 0.9 |
| VIII. North and Central America | 0.2 | 0.8 |
| IX. South America and other Regions | 9.6 | 7.8 |
| | 100. | 100. |

In respect of the various British ports the trade was distributed in the following percentages:—

| Year | East coast | | | West coast | | | All Ports (including ports not specified) |
|------|------------|------------|--------|-----------------|------------|-----------|---|
| | Scot-land | North East | Humber | Bristol Channel | North West | Scot-land | |
| 1913 | 11.3 | 31.3 | 12.1 | 40.7 | 1.0 | .3 | 100 |
| 1925 | 9.7 | 34.6 | 7.1 | 45.1 | 0.4 | 2.6 | 100 |

The table shows there has not been much variation as between the pre-war and post-war years.

The decrease in the export of British coals of late years is due to a variety of reasons, in addition to the reason already named, viz., the increased productivity of other nations. The high price of coal during the World War and for some time thereafter directed the attention of users of fuel to other sources of heat and power, e.g., peat, oil, the generation of electricity hydro-electrically, and also intensified the practice of the more economical use of fuel. With falling prices, however, these restrictive influences will be minimized. There has been, too, on the part of some countries, a desire to erect barriers against the importation of coal; thus, the Soviet Government restricted imports to reduce payments abroad, and forced the use of native coal in north-west Russia, even though an extensive subsidy was necessary to secure this. The French Government also recently (1928) imposed restrictions as to importation of coal.

The average selling price of coal per long ton at the pit's mouth in Great Britain over the period 1905–1926 and the price of coal exported from Great Britain for the same years was as follows:—

| Year | Price at the pit's mouth | | Price of ex- ported coal | | Year | Price at the pit's mouth | | Price of ex- ported coal | |
|------|-----------------------------|----|-----------------------------|----|------|-----------------------------|----|-----------------------------|----|
| | s. | d. | s. | d. | | s. | d. | s. | d. |
| 1905 | 6 | 11 | 10 | 5 | 1919 | 27 | 4 | 47 | 3 |
| 1910 | 8 | 2 | 11 | 7 | 1920 | 34 | 7 | 79 | 11 |
| 1913 | 10 | 2 | 13 | 11 | 1921 | 26 | 2 | 34 | 10 |
| 1914 | 10 | 0 | 13 | 6 | 1922 | 17 | 8 | 22 | 6 |
| 1915 | 12 | 6 | 16 | 8 | 1923 | 18 | 10 | 25 | 1 |
| 1916 | 15 | 7 | 24 | 3 | 1924 | 18 | 10 | 23 | 5 |
| 1917 | 16 | 9 | 26 | 6 | 1925 | 16 | 4 | 19 | 10 |
| 1918 | 20 | 11 | 30 | 3 | 1926 | 19 | 6 | 18 | 6 |

It will be observed from the above table that, while the home prices did not soar unduly during the war period of control, export prices reached very high figures. The former was due to the Price of Coal (Limitation) Act then operative. (See Section XI.)

Sale and Distribution of British Coal.—There are 1,400 separate colliery undertakings in Great Britain, owning 2,500 mines, all engaged in the disconnected disposal of their produce through the selling agencies attached to, or disconnected from,

their concern. Thus in the great northern coalfield it is usual for the coal to be sold to merchants and others through an agent or "fitter" as he is locally termed, who is an official of the colliery company. In other cases the general manager of the colliery, the managing director or the colliery owner acts as the salesman, and

FIG. 26.—DOMESTIC EXPORTS OF COAL OF ALL KINDS, INCLUDING THAT SHIPPED AS BUNKER COAL FOR STEAMERS ENGAGED IN OVERSEAS TRADE

in others outside agents perform this function. One great object being to keep the colliery at work, long-term rather than short-term contracts are sought, the period varying from two or three to six months, or even a year; six and twelve month periods, however, are the more common in the case of large contracts. When prices are very high or very low, the tendency is towards short contracts.

Coal in Britain is seldom if ever sold on an analytical or calorific basis, but under one of the very many commercial names which may or may not—the latter is generally the case—have any reference to the seam from which it is derived. Thus "Wallsend," which originally was the coal from the High Main Seam at Wallsend Colliery on the Tyne, is now merely a name for certain high class house-fire coals. Similarly D.C.B.s (an abbreviation of Davisons, Cowper, Bothal, well known Northumbrian collieries), Derbyshire Brights, Derbyshire Hards, Best South Yorkshire Hards, Best Admiralty Smokeless, etc., have no reference to the seam of derivation, but in the trade itself do represent a certain standard of quality, and certain of the many trade names have a world-wide reputation for excellence as steam, gas, coking or domestic coals.

Few collieries engaged in the British home trade sell direct to customers, but the coal is sold at pit mouth prices to the coal merchants, who bear the cost of transportation to the distributing centre, or the wholesale merchant, sometimes termed a "factor," may dispose of his supplies to smaller merchants, and so on. The public is often at a loss to understand why there should be so great a difference between the price of the coal at the pit's mouth and that which they have to pay delivered into their cellars, even when the extent of the railway charges are known. The difference is accounted for by the many hands through which the coal has to pass from pit to cellar. The crying economic need of the day would appear to be simplicity in distribution. Coal for export also, to a large extent, sold through the medium of merchants, the latter undertaking the risk of transport and distribution.

United States of America.—The coal produced in the United States was estimated in 1922 to be distributed thus:—

| | Per cent of the production |
|-----------------------------------|----------------------------|
| Domestic consumption | 13 |
| Railways | 28 |
| Public Utilities | 12½ |
| Iron and Steel Industry | 15 |
| General Manufacturing | 19½ |
| Export and Bunker Trade | 12 |
| | 100 |

Of the total output of 591,721,000 tons in 1926, there were exported 41,997,495 tons, which was a record in export for that country, the great increase being due to the national lock-out in Great Britain. This figure includes bunker coal shipped in vessels engaged in overseas trade. About the same amount of "soft" coal is devoted to domestic consumption as anthracite. Of the production, about 43% takes place in the summer (April 1 to Oct. 1), and 57% in the winter.

In the matter of sale and distribution of coal, the machinery in the United States does not differ materially from that in Great Britain. Some 50% of the coal is marketed by the producing companies, but even they do not as a rule sell directly to the ultimate consumer. There are, according to Mr. E. T. Devine (*Coal*, by E. T. Devine), 1,500 wholesale dealers in coal, 40,000 retailers (*i.e.*, one to every 600–700 families), and 8,000–10,000 producers.

The anthracite contained within a small area of a single State, *viz.*, Eastern Pennsylvania, has a highly concentrated ownership, 90% of the reserves being owned by the ten railway companies. The capital value of the anthracite industry is estimated at about \$990,000,000. The vastness of the bituminous or "soft" coal industry is indicated by the fact that the coal areas under operation are contained in about 30 of the States, and in 1920, a year of strong demand for coal, there were 12,122 corporations, partnerships and individuals operating 14,766 coal mines.

The production of "soft" coal is on the increase, and this over-production is one of the great troubles with which the United States has to contend; mines being equipped and manned to produce twice their present output, it is not surprising that in 1923 only 179 days were worked on the average. With this capacity for over-production the necessity of the United States to find markets for her coal outside her own border is obvious, and it is interesting in this connection to compare the average export value (*f.o.b.*) in Great Britain and the United States of coal exported to South America—the coal market most available to the United States—together with average freights during two "spot" months, July and August, in 1925:—

| Country to which exported | Great Britain | | | United States | | |
|---------------------------|--------------------|----|-------|--------------------|-------|-----------|
| | Value per long ton | | Total | Value per long ton | | Total |
| | s. | d. | s. d. | s. | d. | s. d. |
| Argentina | 24 | 1 | 16 5 | 40 6 | 18 5 | 16 34 5 |
| Brazil | 22 | 10 | 15 5 | 38 3 | 18 9 | 14 5 33 2 |
| Chile | 18 | 8 | * | * | 17 10 | * |
| Uruguay | 22 | 2 | 15 6 | 37 8 | † | 16 * |

*Information not available.

†No coal exported.

Germany.—The German exports of coal for 1925 rose to 13,500,000 tons, and for 1926 to 28,774,070 tons. Taking the frontiers as they existed in 1925, the consumption in 1913 was 156,000,000 tons, which is not far short of the British home consumption in 1913 of 189,000,000 tons, and points to the increased industrial activity of Germany. The chief consumption of lignite was in the generation of electrical energy. In 1913 lignite was the source of 23% of the power generated in Germany, and in 1922 of 41.2%; the generation of electric power more than trebled in the 10-year period 1913–22, amounting in the latter year to 7,200,000,000 kw. hours. Increased saving in fuel consumption in large power plants and increased use of lignite in the generation of power have liberated a greater quantity of high class "black" coal for export, which competes with British coal in European and other markets.

In Germany the colliery owners must by law sell through syndicates arranged according to districts. A severe penalty is imposed on any owner selling coal outside the syndicate of the district in which his colliery is situated. The syndicates, which are not worked in order to make profit, determine the output of each colliery and fix the selling price of the coal, all coal being divided into classes, *e.g.*, gas coal, coking coal, steam coal, etc. There is one price only for any given class, except in respect of

coals grading from steam into anthracite, intermediate or "dry" steam coals; in these "border line" cases there may be more than one price.

All of these syndicates are combined into the *Reichskohlenverband* over which is a coal council composed of representatives of the coal owners, workmen and consumers' associations, termed the *Reichskohlenrat*, which has conferred upon it, by Government, power to make laws and regulations for the control of the coal mining industry, subject, however, to a power of veto vested in the Minister of Economics (*Reichswirtschaftsminister*). There are at least 100 members of the *Kohlenrat*, 25 of whom are appointed by the management, 25 by the miners and ten by the Reichstag, and the rest—of whom not more than one-third may be officials—by the president of the Reich.

More coal is now being produced in the world than in the past, and more economy is being practised in its use; that is to say, it is being put to better use than previously by improved methods of burning for steam raising and the generation of electricity, by the more extensive use of gas for heating, cooking and for driving internal combustion engines, by the use of powdered fuel, and by other means of obtaining a higher percentage of the available heat value of the fuel. But as Prof. Jevons states, "It is wholly a confusion of ideas to suppose that the economical use of fuel is equivalent to a diminished consumption. The very contrary is the truth."

Speaking generally, it is probable that the economy does lead to increased consumption, but it is doubtful whether it does so to the extent of the economy effected.

SECTION IX.: COAL: HISTORY OF LEGISLATION AND COMMISSIONS OF ENQUIRY

The history of ameliorative legislation in respect of the coal mines and miners of Great Britain may be said to date from the year 1778, when a law was passed which enacted that the state of life-slavery to which the miners of Scotland were subjected should come to an end, for at that time they were working under laws by which they were practically slaves. Able-bodied men were paid ten pence a day for hewing coal; their womenkind, acting as bearers in carrying the coal out from the workings and up the shafts, receiving but threepence a day. The workers forming part and parcel of the concern, passed from owner to owner with the colliery as so many chattels. The emancipation was to be gradual and it was not until 1799, when another act was passed, that complete freedom was granted to the Scottish miners. The pay and conditions of employment of mine workers in other parts of Britain were, however, at that time in advance of those of Scotland.

Repeated disasters in the coal pits led to the formation in Sunderland, in 1813, of a Society for the Prevention of Accidents in Coal Mines, and it was the members of this society who were instrumental in engaging the services of Sir Humphrey Davy in the investigations which culminated in 1815 in the invention of the safety lamp.

About the middle of the last century may be regarded as the time when great advances were made in mining methods and in the conditions and social status of the mine workers, the latter being due in part to the action of the miners themselves and in part to the general advance in public conscience. Colliery bonds (yearly bonds binding the miners to work on certain terms) of 1763 show that combinations of the miners were prohibited at that time. Combinations of the coal owners in the north of England for the purpose of regulating the vend of coals, and so securing higher selling prices, had been in operation off and on for two centuries before the workmen combined among themselves (1825) with a view to restricting production and obtaining better terms for their labour. The Association of Colliers on the Rivers Tyne and Wear, consisting of 4,000 persons (*Fossil Fuel*, p. 299 note), was formed in 1826 immediately after the repeal of the Combination laws by act of parliament (5 Geo: IV. c. 95).

Committees of the House of Commons had been appointed in the year 1800 to enquire into the state of the coal trade and their reports were published in 1829, in which year, and again in 1830 and 1836, the Lords appointed a select committee "to enquire into

the coal trade." Though these sumptuous volumes of evidence and reports constitute a mine of wealth as to the conditions prevalent in the industry at this time, it remained for that great protagonist in the battle for fair conditions for labour, Lord Ashley, afterwards Earl of Shaftesbury (as the outcome of the report of the commissioners for enquiring into the conditions of children employed in mines), to bring in a bill which became law in 1842. This bill prohibited the employment below ground of women and girls and of boys below the age of ten years. Social inspection also opened the way for mine inspection, which was introduced under the Coal Mines Regulation Act of 1850. This was followed by the Regulation Acts of 1855, 1860, 1872, 1887, 1894, 1905 and 1908, the Mines Accidents (Rescue and Award) Act, 1910, and, finally, the Coal Mines Act of 1911, which is still in force. The Act of 1911 deals with such matters as the qualifications of managers and other officials, ventilation, safety lamps, shafts and winding, travelling roads and haulage below ground, support of roof and sides, signalling, machinery, electricity, explosives, prevention of coal dust, inspection as to safety, withdrawal of workmen, surveys and plans, safety measures against inundation, weighing of coal and payment of workers, hours of employment, provisions as to health, notices of accidents, reports, investigations and inquests, penalties, rescue and ambulances.

In addition to the Mines Regulation Acts, there have been passed various Factory and Workshop Acts, which affect such parts of the surface arrangements at mines as, for example, coke ovens, while the Education Acts enforce certain conditions bearing on the education of children and impose penalties for employing a child in contravention of those acts. The Workmen's Compensation Acts of 1897 and 1906 render the employer liable to the workmen for injuries received whilst at work. Among these various measures may be mentioned the Elementary Education Acts of 1870, 1876, 1880, 1891; the School Attendance Acts 1893, 1899; Employment of Children Act, 1903; Employment of Women Act, 1907; Employers' Liability Act, 1880; Factory and Workshop Acts, 1878, 1883, 1888, 1891, 1895, 1901; Fatal Accidents Inquiry (Scotland), 1895; Notice of Accidents Act, 1894, 1906; Truck Act, 1831, 1887, 1896; and the Minimum Wage Act, 1911. In 1865-67, resulting from a petition to the House of Commons from the Miners' National Association urging certain reforms, a select committee was set up to enquire into the working of the law in connection with coal mines and recommended, amongst other things, certifications of competency by examination of colliery managers. Hence the act of 1872.

The Work of Commissions and Committees.—The first royal commission to be appointed in relation to coal mining was that of 1866-71 presided over by the then Duke of Argyll, the reason for its appointment being the alarm raised by the publication in 1865 of Prof. Stanley Jevons' famous book *The Coal Question*, in which he pointed out that, if the great progressive expansion in the production and consumption of coal continued, "the end of the present progressive condition of the Kingdom" would probably take place within 100 years. Various figures were given as to the duration of the coal supplies, 360 years being the lowest. No legislation resulted from the report of this commission. The next royal commission was that on accidents in mines appointed in 1879, which reported in 1886, the Coal Mines Regulation Act of 1887 being the result.

In 1886 an agitation against royalty rents by both colliery owners and workmen led to a memorial of 60 members of parliament characterizing the system as a "gross hindrance to the mining industry." In 1890 a royal commission on mining royalties was set up with Lord Northbrook as chairman. This commission reported in 1893. Amongst other conclusions come to was that "the system of royalties has not interfered with the general development of the mineral resources of the United Kingdom," and they dismissed the question of nationalization.

In the year 1901, the then chancellor of the exchequer, Sir Michael Hicks-Beach, in order to make his budget meet, put a tax of 1d. per ton on export coal, an action which raised much indignation on the part of colliery owners, miners and economists, and eventually induced the Government to set up a commission to re-

view the matters which had come before the 1871 commission. This commission, which was under the chairmanship of Lord Allerton, reported in 1905. The report is still a very valuable work of reference. Of their many conclusions two of considerable interest are worth recording. They foresaw a great development in the use of the steam turbine, powdered fuel and gas stoves. They did not believe there was any "real substitute" for coal as a source of power. They hoped for the establishment of great central electrical generating stations, and were sceptical—in this they were in error—as to the substitution of oil for coal in the Navy. They disapproved of the tax on coal, which was repealed by the Liberal Government in 1906.

In 1906 the miners' eight-hour day committee was appointed, reporting in 1907, and in 1908 an act regulating the hours of employment of miners was passed, which has come to be known as the Miners' Eight-Hour Act.

The period 1896–1911 was one of intense activity as to investigation into the health and safety of miners, for during that period there were set up and reported the explosives testing committee (1897), the first electricity in mines committee (1902), the second electricity in mines committee (1911) and the committee on bobinito (1907). In 1906 a royal commission on mines was appointed under the chairmanship of Lord Monkswell to deal with questions of health and safety and reported in 1909. The outcome of this report was the appointment of a chief inspector of mines, of which Mr. (now Sir) Richard Redmayne was the first occupant, a reorganization of the mines inspectorate, and the passing of the 1911 Mines Act, to which reference has been made already. The mines (rescue and aid) committee, set up in 1910, reported in the succeeding year on the training of rescue corps and maintenance of rescue stations, while the explosions in mines committee, sitting from 1910 to 1914, issued a series of reports giving the result of their experiments carried out at the Home Office research station at Eskmeals in Cumberland. This station is now transferred to Buxton, where it is under the safety in mines research board of the Mines Department. The short Mines Act of 1914 was passed in order to remedy a few oversights in the comprehensive act of 1911.

During the period intervening between the passage of the 1911 act and the outbreak of the World War, several departmental committees were set up to enquire into various subjects connected with coal mining, such as the committee on washing and drying accommodation in mines (1913), dealing with pit-head baths, as a result of which certain regulations were made in regard to the matters reported on; the committee on spontaneous combustion in coal mines (1912–21), which made recommendations to which effect has been given, while the report of the mines rescue apparatus research committee formed the basis of part 3 of the General Regulations of July 20, 1920. The Coal Mines (Minimum Wage) Act was passed in 1912. Though its duration was to be for three years, it is still in existence, having been maintained by Expiring Laws Continuance Acts.

During the period of the World War special legislation affecting the coal mines of Great Britain was passed, the character and object of which are dealt with under Section XI. of this article. But there were certain committees which sat during part of the war period, unconnected with war conditions, which were of far-reaching importance, such as the committee on the coal trade after the war and the coal conservation committee. This last-named committee became on the establishment of the Ministry of Reconstruction a committee of that department, and among its results were the setting up of the Fuel Research Board, and proposals as to the establishment of an electric power scheme for Great Britain, which is now in course of being carried into effect.

An important committee, too, was the acquisition and valuation of land committee, which amongst other matters dealt largely with the question of mine royalties, and as a result of whose report (1919) the Mines (Working Facilities and Support) Act was passed in 1923, giving power to the railway and canal commission to override the rights of owners of land and minerals so as to secure the effective working of coal, and dealing also with ques-

tions relating to support.

The Sankey Commission.—Since the war several important acts have been passed as the result of the findings of other commissions and committees. The most important of these was the coal industry commission which, under an act of parliament passed for the purpose, was clothed with statutory powers for enquiring into the position of, and the conditions prevailing in, the coal industry. This, perhaps the most important royal commission on coal that has sat, was presided over by an eminent judge of the high court, Sir John Sankey, G.B.E. The commission took within its purview many matters connected with the coal industry, such as health, safety, costs, profits, hours of work and conditions of employment generally. It considered alternative methods for the future conduct of the industry, as, for instance, the existing system of private ownership and control, nationalization, and, as an alternative to nationalization, a system of aggregation of colliery interests and co-partnership.

Three divergent interim reports were presented on March 20, 1919. The chairman and the three Government nominees (of the six persons selected because of their economic knowledge) recommended a "seven-hour" working day instead of the existing eight hours, "and, subject to the economic position of the industry at the end of 1920," a six-hour day; an increase of two shillings per shift in the wage of those "classes of colliery workers, employed in coal mines or at the pit-heads of coal mines, whose wages have in the past been regulated by colliery sliding scales," and, in the case of workers under 16 years of age, an advance of one shilling a day. There was included in this report a paragraph which caused much stir in mining circles. It ran,

"Even upon the evidence already given, the present system of ownership and working in the coal industry stands condemned, and some other system must be substituted for it, either nationalization or a method of unification by national purchase and/or joint control."

The report stated that it was "a matter for careful consideration whether 1d. per ton should not be at once collected on coal raised and applied to improve the housing and amenities of each particular colliery district." On the output then being procured this meant about £1,000,000 a year.

The three miners' representatives and the three nominees of the miners (of the six persons noted for their economic knowledge) signed another report which was somewhat longer than the first mentioned, and whilst advocating an advance of 30% in wages and a six-hour working day, constituted also a closely reasoned argument in favour of the complete nationalization of the coal mining industry.

The three colliery owners' representatives, on the other hand, in a somewhat brief report, took up the attitude that they had not to decide the question as to "what amount we would desire colliery workers to receive to enable them to attain a higher standard of living, but the amount to which their existing wages ought to be increased, regard being had to a reasonable standard of living amongst the colliery workers and the effect of any increase of their wages on the development of the coal industry and the economic life of the country." They also opposed any decrease in the working hours. As regarded nationalization or unification of ownership of collieries, they stated that "such evidence as has been placed before us is insufficient to enable us to pronounce any judgment."

The Government accepted the majority (the chairman's) interim or first stage report "in the letter and the spirit," as a result of which the Seven Hours Act and the Mining Industry Act of 1920 were passed.

On June 20 of the same year the commissioners made four divergent final reports, one by the chairman, another by Sir Arthur Duckham (one of the six gentlemen eminent in economic knowledge), another by the miners' representatives and their three nominees (of the six "economic" members of the commission) and a fourth by the colliery owners' representatives and two of the Government's nominees of the six economic members.

The chairman reported in favour of acquiring the coal royalties and mines by purchase for the State. Sir A. Duckham advocated,

amongst other things, State ownership of the minerals (royalties) by purchase, a system of unification in areas under private enterprise, the setting up of pit committees, and the multiple shift system. The miners' representatives advocated State organization and ownership (*see* subsequent Section X.). The fourth report of the colliery owners and two of the economic members stated, amongst much other matter, "that the evidence submitted to the commission afforded no ground for belief that nationalization would have the effect of reducing the price of coal, in fact it pointed the other way, and that they believed in any form it would be detrimental to the development of the industry and the economic life of the country; nor would it lead to peace." They favoured purchase by the Government of the coal royalties and recommended the setting up of pit committees, and district and national councils.

The Government practically accepted none of the reports in their entirety and brought in a bill for setting up pit committees, district and national councils, but the leaders of the miners declined to accept it as a settlement. A national stoppage of the miners was, however, averted.

The coal trade remained in a very disturbed state, and in 1924 a court of enquiry under Lord Buckmaster was set up, and another in 1925 under the well-known Counsel Mr. MacMillan, dealing with certain aspects of the industry. In 1925 the Mining Industry (Welfare Fund) Act was passed prolonging the Welfare Fund for another five years. There was a state of worldwide depression in the coal mining industry, production being in excess of demand. In July 1925 the British Government decided to make to the coal industry a financial subvention as from Aug. 1 of that year to April 30, 1926, by which wages would continue to be paid at the current rate. By March 31, 1926, this subsidy had reached £19,000,000.

The Samuel Commission, 1925.—In Aug. 1925 a royal commission was appointed under the chairmanship of the Rt. Hon. Sir Herbert Samuel, G.B.E., "to report upon the economic position of the coal industry and conditions affecting it, and to make any recommendations for the improvement thereof." The commission, consisting of four persons unconnected with the industry, issued on March 6, 1926, one of the most exhaustive and masterly documents ever produced in connection with the coal industry of Great Britain.

The commission, besides hearing fresh evidence, made a close study of the evidence which had been given before the Sankey commission. The following is a very brief and condensed summary of the findings and recommendations of the commission:—

They condemned the principle of a subsidy. They could not agree with the view of the coal owners that little can be done to improve the organization of the industry, and that the only practicable course was to lengthen hours and lower wages. They considered the problem as divisible under two heads—the permanent and the temporary aspect. The immediate problem to be faced included the fact that, excluding the subsidy, 73% of the coal was produced at a loss and the commission arrived at the opinion that, "If the present hours are to be retained, we think a revision of the 'minimum percentage addition to standard rates of wages' fixed in 1924 at a time of temporary prosperity, is indispensable." They hoped that no increase in hours would be necessary. They deemed it essential that there should be, as heretofore, considerable variation as between districts in the rates of wages, but at the same time advocated the continuance of national "wage agreements" and recommended that the representatives of the employers and employed should meet together, first nationally and then in districts, in order to arrive at a settlement. The revision of the minimum percentage would save the industry from immediate collapse, but it was inevitable that a number of collieries would have to be closed; consequently it might be necessary to arrange for the transference of labour on a considerable scale, in which case the Government should provide funds for the purpose.

With regard to the permanent aspect of the problem, the commission advocated the acquirement by purchase by the State of the royalties; the amalgamation of the collieries into larger

groups which the State, as owner of the minerals, would be able to promote; the promotion of a closer connection of mining with the allied industries, *e.g.*, "the development of electrical supply under the new proposals of the Government should be closely co-ordinated with the generation of electricity at the mines." They suggested the setting up of a national fuel and power committee with advisory powers. They regarded research into the methods of both winning and using coal as being backward. The State should give financial support to the further experiments on a commercial scale which are necessary in the case of low-temperature carbonization. The matter of distribution of coal left much to be desired; large financial advantages might be gained by the formation of co-operative selling agencies—they were especially needed in the export trade. The Government should consider the establishment of an official system for the sampling and analysis of coal so as to encourage selling on a specification and guarantee. Local authorities should be empowered to engage in the retail coal trade. Larger mineral wagons should be used and a greater concentration of ownership thereof effected, and a standing joint committee of the Ministry of Transport and the Mines Department be formed to promote these measures. Whilst the standard length of the working day, which averaged 7½ hr. underground, should remain unaltered, "the optional re-distribution of hours within the present weekly total, over a week of five days instead of six, should be considered," and the multiple shift system should be extended. Joint pit committees should be established generally. Payment of men should be on such a basis, where possible, as to give them a direct interest in output. They advocated a family allowance system and profit sharing. For all new collieries a proper provision of houses for the workers should be a condition of the lease. The general establishment of pit-head baths was necessary and when prosperity returns to the industry they considered that annual holidays with pay should be established. The industry should be continued under private enterprise.

Although the owners, under pressure, accepted the report in principle, it was rejected by the miners, and on Saturday, April 29, 1926, the men ceased work. To support them a general strike was ordered (*see* GENERAL STRIKE), but in a few days this was abandoned. The miners, however, remained idle throughout May and June and the attempts made by the prime minister and others to bring about a settlement of the dispute were unavailing. In June the Government introduced legislation into parliament to carry out the recommendations of the Samuel commission, and (1) the Coal Mines Act 1926, which permitted of increasing the time below ground of workmen by one hour, and (2) the Mining Industry Act, 1926, which gave effect with two important exceptions to the recommendations of the Samuel commission, were passed.

Space does not permit of a description of the very important provisions contained in the latter act, *e.g.*, those for facilitating amalgamations of collieries, the extending of the Mines (Working Facilities and Support) Act, levy on royalties for purposes of erecting pit head baths, limitation of recruitment of labour in the industry for facilitating profit-sharing schemes, pit committees, etc. A number of committees were also set up as the outcome of the report of the Samuel commission to deal with matters referred to therein, *e.g.*, the fuel and power council, the mineral transport committee, the committee of co-operative selling in the coal mining industry; the latter has reported already.

During the last 60 years there have been in connection with the British coal mining industry nine royal commissions, over 30 committees of enquiry, and 26 acts of parliament. Perhaps no branch of industry has been subjected to so much and such stringent state regulation as that of coal mining in Great Britain, with a view, in a great measure, to the protection of the miners. Socially, morally and financially the status of the workers has greatly advanced since 1850, and coal mining has developed into a branch of engineering requiring the most skilled engineers. This high degree of skill is essential because the richer and more accessible coal deposits were largely worked out in the earlier periods of coal mining in England.

SECTION X.: COAL: THE QUESTION OF NATIONALIZATION

A policy which of late years has been espoused by the Miners' Federation of Great Britain is that of the nationalization or socialization of the coal mining industry. Whatever form it takes, whether ownership by the State, with State control, or some form of guild socialization—as, for instance, ownership by the workers in the industry for their benefit—it implies the elimination of the individual employer and the destruction of private enterprise.

The miners, however, did not welcome Government control of the coal mines when it was first mooted in Dec. 1916, being suspicious of what was entailed thereby. On Dec. 20, 1916, the executive of the Miners' Federation adopted a resolution, "That the executive views with the utmost concern the declaration of the prime minister that the Government contemplate taking control of the whole of the mines of the country, and before any definite action is taken, we ask the prime minister to grant an interview to the executive committee at the earliest possible date." Eventually, that view has completely changed.

At the beginning of 1919, when the miners put forward a series of demands, there was included a demand for the "nationalization" of the collieries. And again, upon the issue of the four separate and diverse reports of the Sankey commission (*see* SECTION IX.), the report of the miners' representatives advocated State organization and ownership. The report of the chairman (Mr. Justice Sankey) recommended the immediate acquirement of the coal royalties for the State, which was to pay just compensation to the owners thereof. He also recommended a scheme for the local administration of the collieries, and that legislation be passed for acquiring them for the State, after the scheme had been worked for three years from the date of the report; during that time the coal control, then in existence, was to be continued. The reasons for nationalization of minerals and collieries which animated the miners' representatives and the chairman of the commission may be epitomized as follows:—

(a) Coal being a principal national asset of the United Kingdom, and a wasting asset, it is in the State's interest that it should be worked and used to the best advantage.

(b) The ownership of coal is vested in about 4,000 owners, among whom, though many are reasonable, there are some who are a hindrance to the development of the industry.

(c) Under a system of corporate ownership, boundaries of undertakings are arbitrary and irregular, making it difficult to work the mines, while the coal at present left between the separate mines is lost.

(d) Drainage and pumping of the mines could be more effectively carried on under a system of nationalization than under individual ownership.

(e) Competition between coal owners for the export trade frequently prevents the industry from getting the full value of the coal.

(f) The system of inland distribution of coal being in the hands of many private individuals, the consumer is unable to obtain the coal as cheaply as he should. It is estimated that there are 28,000 retail distributors of coal in the United Kingdom.

(g) There are about 3,000 pits owned by about 1,500 companies or individuals in the United Kingdom. Were these combined under State ownership, standardization of materials and appliances would be possible, with the resulting economies.

(h) Though all the above economies and improvements could be effected under a system of unification without nationalization—by a system of "rationalization," as it has come to be called—it is, or was, agreed that, as the workers think under private ownership they are working for the capitalist, and when a strike takes place a contest between labour and capital is set up which is much less likely to apply with the State as owner.

The miners' representatives were opposed to any compensation whatever being paid to the owners of the coal (royalty owners). Sir Arthur Duckham, a Government nominee on the commission, reported in favour of unification under private ownership. The colliery owners' representatives and two of the Government nominees on the commission reported in favour of the State purchase of the coal but against nationalization of the collieries. They stated that "the evidence submitted to the Commission affords no ground for belief that nationalization would have the effect of reducing the price of coal," and that "without co-operation, nationalization, even if otherwise advisable, would in no way secure increase of output or continuity of production. The evidence has

clearly shown that strikes are not prevented by State ownership and management," and were emphatic that nationalization "in any form would be detrimental to the development of the industry and to the economic life of the country." The Government of the day rejected nationalization, and after the great strike of 1920 the objective for the time being of the miners' representatives had got narrowed down to a national pool of wages and profits. But nationalization of minerals and mines is the avowed policy of the Labour Party in Great Britain.

As a remedy for such defects as unscientific use of coal, costly getting of coal, imperfect selling and transportation arrangements, etc., the Samuel commission (reported March 6, 1926) did not recommend the adoption of the policy of nationalization. They remained unsatisfied that such a system was workable or that it offered a clear social gain. "We perceive in it" they said (p. 233 of the report) "grave economic dangers, and we find no advantages that cannot be obtained as readily or more readily in other ways." They were of the opinion (p. 237) that, "The way to prosperity for the mining industry lies along three chief lines of advance: through greater application of science to the winning and using of coal, through larger units for production and distribution, through fuller partnership between employers and employed. In all these respects progress must come mainly from within the industry."

The author of *Coal Mining Industry during the War* in the concluding chapters of his work, refers thus to nationalization:—

"The economies of administration and working attainable under a system of aggregation must be patent to every broad-minded and enquiring student of the mining industry. Keen competition between rival coal owners allows the foreigner in normal times to exploit the coal output of the country. Great economies could be achieved, too, by a centralized system of purchasing of stores, and important far-reaching economies could be secured by centralization of pumping and to some extent winding plants, and further, underground haulage would be simplified and cheapened by the abolition of eccentric boundaries. . . . The gains or drawbacks of nationalization, on the other hand, hinge upon definite principles of human action and experience. Whatever results may accrue from such a policy, from the record of observation I find great difficulty in believing that it would make for efficiency. During the period of control the representatives of the State did their best, and they were often unfairly criticized, but it is certain that no experienced head amongst them would care to put forward the claim that public management has a genius for either efficiency or economy. It was imperative at the time to impose unified action in important matters, where there was no existing machinery within the industry capable of doing so. But the virtue was in the co-ordination and not in the head directing it, and there can be no doubt that joint action from within, had it been available at the moment it was required, would have produced a more effective and economical mechanism. A prominent instance of this was the system of voluntary district coal distribution which was carried on by a committee of the coal owners. Even if nationalized control were not vetoed by the inherent physical difficulties of the case, it would still have the disadvantage of removing from the industry the great energizing forces of personal responsibility and initiative."

In Great Britain and America there are no State-owned mines. The German State formerly owned a large number of collieries. The Prussian State owned and managed three large coal mines in Upper Silesia, now in Polish territory, three lignite mines and eight bituminous coal mines in the Ruhr, together producing about 9,500,000 tons per annum. Prussia also had control of the Hibernia coal mines, which, however, were run on the lines of a private company. In 1924 all these mines were denationalized, though the State continued to hold all the shares and other capital, the only difference being that, though the directors are appointed by the State, the officials and control generally of the mines are not under the State.

Russia. All the collieries in Russia, once privately owned, are under the Soviet. Figures based on returns by the Soviet—the conditions being those of gradual recovery from war-effects—present (1928) a poor comparison with pre-war conditions. A considerably reduced output has been obtained and that output only with the aid of important State subsidies. In the fiscal year ending Sept. 1924 the coal mining industry received subventions in cash amounting to 24,800,000 chervonets (1 ch. = £1.15) and a credit of 50,000,000 ch. in addition. The industry is greatly in arrears with payment of taxes. The position of the miner is far worse than before the war; in the Donetz basin he received, in March 1924,

15 gold roubles compared with 36.8 gold roubles in 1914 calculated upon the index cost of living. The output in 1913, exclusive of the area assigned to Poland, was 28,990,000 tons, whereas in 1924 it was only 14,580,000 tons; the country cannot even absorb this greatly diminished output. In 1913 the output per man per annum was 149.4 tons; in 1924 it was only 86.8 tons.

Holland. Holland has some State coal mines, the production from which in 1924 exceeded that from the privately owned mines for the first time. The State-owned mines produced 2,912,899 tons out of a total for the country of 5,787,020 tons. The gross working profit from all the State mines in 1924 was 7,320,000 florins as compared with 8,340,000 florins in 1923.

British Empire. In the British Empire there are several cases of State ownership of collieries on a very small scale, e.g., the Udi mine in Nigeria, the Mount Mulligan mine in Queensland and the James and Liverpool collieries in New Zealand.

SECTION XI.: COAL: CONTROL METHODS IN THE WORLD WAR

In times of war and national emergency, when industry is paralysed for lack of motive power, the overwhelming importance of coal is emphasized. Coal is not only the prime factor in the manufacture of nearly all war materials, and in the mobilization of shipping, but in the case of Britain, it is a prime article of exchange for the foodstuffs that are imported. The cost of living is further very largely affected by the price of coal. During certain periods of the war the trading value of coal became very pronounced, for a free exchange in coal did not exist. Certain Governments, notably the British and German, held the delivery of coal under control. For instance, Britain supplied coal to Norway and Sweden, at a price subject to those countries giving in exchange return cargoes of pit timber and certain classes of high grade iron ore and steel billets. To Sweden also at one time bituminous coal and anthracite were supplied subject to the release for transport to Russia of certain medical stores of which the latter country was in great need. Similarly, Switzerland relied almost entirely on German coal for industrial purposes, and Germany used this weapon as a means to press for "compensatory goods," and also obtained iron ore in like manner from Sweden.

By a systematic development of the policy of granting supplies of coal for bunkering purposes only upon condition that those receiving such supplies would render certain services to the British empire and her Allies, or would abstain from giving certain facilities to their enemies, the firms who controlled the marketing of British coal were gradually able to exert a degree of pressure upon neutral shipowners and manufacturers which formed a valuable contribution towards the economic measures directed against the enemy. But, the immediate effect of the war on the coal trade of Great Britain was also to close several important foreign markets against her. Transport facilities, by reason of the diversion of rolling stock and shipping to military purposes, was also impeded. The result was a temporary glut of coal at the collieries for home consumption.

The Allies, especially France and Italy, became largely dependent on Britain for their supplies of coal, the latter country entirely, while France's demands were soon double that of the normal importation. The great expansion in the manufacture of the munitions of war at home greatly augmented the fuel requirements of the iron and steel works, and on top of all this the war requirements made a constant drain on the number of miners. Up to the end of March 1916, no fewer than 282,000 men from the coal mines had voluntarily enlisted in the fighting forces. So that, although the decline in exports of coal and coke during the year 1915 amounted to about 14 million tons, this was more than balanced by decreased output, amounting to nearly 12,500,000 tons, and increased demands for home consumption. The average pithead price of coal rose from 9s. 11.21d. in 1914 to 12s. 4.8d. per ton in 1915.

The Coal Mining Organization Committee.—This body consisting of representatives of the colliery owners and miners, presided over by the chief inspector of mines, was set up by the Government in Feb. 1915 to organize the industry to the best

advantage to meet the exigencies created by the war. It had no plenary powers; it could only investigate, report and arbitrate. It continued in almost constant session until complete financial control of the industry by the State was instituted in 1917, and but for the very strained relations between the colliery owners and workmen in South Wales, which culminated in a complete impasse at the close of 1916, it is probable that the committee could have functioned successfully throughout the war. Two other committees dealing with coal problems were established on the advice of this committee, namely, the coal exports committee, under whose control was placed the whole of the export trade of the country in coal, and the coal and coke distribution committee, which dealt with the inland distribution of supplies.

In 1916 the output of coal showed an increase of over 3,000,000 tons on the previous year, and the average pit-head price had risen to 15s. 2.57d. per ton. Exports still further decreased, but this was occasioned by the unavoidable restriction which had to be imposed to meet home requirements, due to the starting of munition factories and the extensions of works. On the advice of the coal mining organization committee, the Government instituted the Price of Coal Limitation Act, which became law as from July 29, 1915, and remained in being until the end of March 1921, being repealed when Government control ceased.

The coal trade had reached a purely artificial state which continued throughout the war, the natural laws governing supply and demand being largely disturbed by Government control of prices and of export. The limitation of the price of coal, which was in the nature of a self-denying ordinance on the part of colliery owners and the miners, constituted one of the chief events in the history of the coal mining industry of Great Britain. It was almost the first attempt at a statutory limitation of the price of an essential commodity and, on the whole, it achieved a remarkable success. By the act, certain maximum pit-head prices for the sale of coal for inland consumption were fixed, the coal owners being left free to obtain the best possible price for coal for export, with the exception of a limitation in the case of coal sold to the Allies. Thus at one time the price of the same coal was for home consumption 16s. 6d. per ton and for export 60s., 62s.6d. and 65s., and after the Armistice actually reached 140s. a ton for export.

Government Control.—Owing to the wage disputes in South Wales terminating in an impasse, the Government took possession of the coal mines in Wales and Monmouthshire as from Dec. 1, 1916, with the object of eliminating war profits, avoiding industrial disputes and securing the best results from labour in the mines during the war. In February of the year following it was succeeded by a more stringent control which was extended to include all coal mines, the three advisory committees mentioned above being merged in the control. An agreement arrived at between the controller and the coal owners as to the compensation to be paid to the latter under the control was confirmed by act of parliament on Feb. 6, 1918.

The management of the collieries remained with the owners, and a profit standard was fixed in respect of each colliery undertaking based on any one of the three years preceding the war which the owner chose to select, such profit being guaranteed to him during the period of control, provided he worked up to a standard output. Eighty per cent of all the profit over and above the guaranteed profit was paid to the inland revenue, as in the case of the excess profits of other concerns. Of the remaining 20% the Government coal controller took 15%, which went to form a pool from which he met deficiencies that arose in respect of the guaranteed profits of any of the undertakings, the colliery owners receiving the remaining 5%.

Perhaps the two most important actions taken by the controller of coal mines were those in respect of the transport and rationing of coal. On Sept. 8, 1917, the Transport of Coal Order was issued, under which Great Britain was divided into 20 areas to which coal produced in each of the production areas might be forwarded by public railway for inland consumption, (1) for steam and manufacturing purposes, (2) for gas and cooking purposes, and (3) for domestic purposes. It was estimated that, on the basis of the year 1917, the scheme would effect a saving in transport of rail-

borne coal of 700,000,000 ton-m. per annum; though it is doubtful whether the saving effected actually reached this figure. The rationing of domestic coal first applied to London under the Household Coal Distribution Order of Aug. 10, 1917.

The Distribution Order, 1917.—Three principal objects were aimed at by this order: the establishment of minimum stocks of coal to be held in reserve throughout the winter; a priority in distribution of any available stocks of coal, in case of shortage, to be conferred on consumers requiring or taking supplies in quantities not exceeding 2 cwt. per week, and restriction in the consumption of coal where it was in excess of the normal average requirements of houses of different sizes. In July 1918 compulsory rationing in respect of domestic coal was made applicable to the whole of England and Wales, and in Oct. 1918 to Scotland also.

End of War Time Control.—The financial control of the coal mines was terminated by the passage, on March 31, of the Coal Mines (Emergency) Act, 1920, which specified that it should be deemed to have ceased as from April 1, 1919.

The financial decontrol of the mines took place on March 31, 1921. As the temporary scheme was drawing to a conclusion the representatives of the owners and workmen met in order to work out a permanent settlement. Their efforts failed, and on April 1, 1921, another national strike took place; it lasted until July 4, when a settlement was arrived at embodying for the first time the idea of profit-sharing.

UNITED STATES

According to recent estimates, those of the International Geological Congress, the United States has about 52% of the coal supply of the world, but in view of the fact that the geological resources are probably almost as closely estimated in the United States as in any part of the globe and that large areas of the earth's surface have been only roughly surveyed and some not at all, this figure may be subject to some reduction. Twenty-eight States, as well as the Territory of Alaska and the Philippine islands, have bountiful supplies of coal, 8 States have only a small quantity in each and 12 States, with the Hawaiian islands, are absolutely without this fuel. Table I. shows the separate production of 28 states and Alaska in 1926 with the combined tonnage of California, Idaho and Nevada.

Some of the figures in the last column of the table—"average tons per man per day"—may be too high in some States because men in those regions frequently go into the mines to shoot coal and load cars on days when the tipples or mines as a whole are not in operation. The figures relate only to active mines of commercial size that produced bituminous coal in 1926. The number of such mines in the United States was 7,177 in 1926; 7,144 in 1925 and 7,586 in 1924. Of the coal mined in 1926, it may be said that 90,772,894 tons or 15.8% was undercut by hand; 52,439,914 tons or 9.1% was shot off the solid; 410,912,680 tons or 71.7% was cut by machines; 16,922,695 tons or 3% was obtained by stripping and 2,318,802 tons or 0.4% was mined under conditions unspecified. There were 174 mines in Class 1A (producing 500,000 tons or over in the course of the year). These

mined 23.6% of the entire tonnage. There were 649 in Class 1B (with a tonnage between 200,000 and 500,000 tons in the year). These produced 34.5% of the tonnage. Class 2 (100,000 to 200,000 tons) numbered 845 and produced 21.0%; Class 3 (50,000 to 100,000 tons) numbered 867 and produced 10.9%; Class 4 (10,000 to 50,000 tons) numbered 1,912 and produced 8.3% and Class 5 (less than 10,000 tons) numbered 2,730 and produced 1.7%.

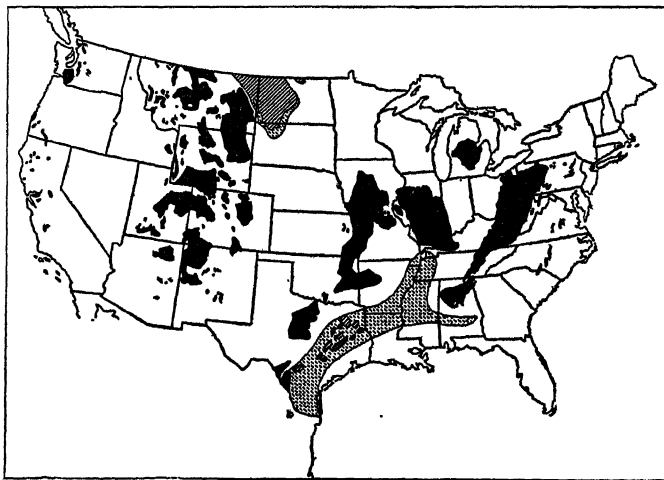

FIG. 27.—COAL WHETHER SUB-BITUMINOUS, BITUMINOUS, SEMI-BITUMINOUS, SEMI-ANTHRACITE OR SUPERANTHRACITE IS DESIGNATED BY THE SOLID BLACK AREAS. LIGNITE OF DOUBTFUL OR UNDETERMINED VALUE IS DESIGNATED BY BROKEN HATCHING; DARKER HATCHING SHOWS LIGNITE FIELDS OF KNOWN COMMERCIAL VALUE

Table II. shows the coal analyses in more important districts.

Pennsylvania Anthracite.—The anthracite region of Pennsylvania until and including 1869 (except in 1865) produced more coal than all the rest of the United States. In that year the output of Pennsylvania anthracite was 17,083,134 tons. Since that time the tonnage of the anthracite field has increased, but the production of bituminous coal and lignite has augmented far more rapidly. The value of anthracite per ton at the mines averages 2½ times that of bituminous. (See ANTHRACITE.)

Methods of Mining.—Most of the coal produced in the United States is mined by room-and-pillar methods which are equivalent to the bord-and-pillar, or post-and-stall, methods of Great Britain. The width of the room varies from 10 to 80 ft. depending on the strength of the part of the roof immediately over the coal, the depth of the seam from the surface, whether it is the purpose to withdraw the pillar and whether an attempt is made not to disturb the surface. Where, as in the Connellsville region of Pennsylvania, the cover is deep and the pillar coal friable, the room width may be only 12 ft. wide, especially, if, as is usual, the extraction of the pillar or "second mining" is to be attempted later. In that case pillars of as much as 80 ft. width have been provided. In many parts of West Virginia, in central and southern Illinois, and in the south-western coal region generally where pillars are not removed, the percentage of recovery may be less than 50. In the Connellsville, Fairmont and Pocahontas regions complete extraction is attempted and 90% is frequently attained. In these regions the pillars are withdrawn retreating and in a long break line extending over two or three entries which is adhered to rigidly in order that no pillar may form a salient angle in the line of goaf, and thus receive more than its due load. No coal is left standing. If it cannot be loaded it must, at least, be shot down, so as to permit the roof to break and fall, relieving the stress on the coal face. In such instances the roof is frequently observed to be torn on the surface, as in longwall workings, some hundreds of feet back of the break line over the still standing coal. The underground breaks of the roof within the area that has been totally excavated doubtless do not connect with these surface breaks. The fractures in the workings appear to project into the goaf, or excavated area, from a line near the break line at an angle to the horizontal of 70 degrees, leaving a corbel of rock along the break line.

COAL AND COAL MINING

TABLE I.—*Production, Value, Men Employed, Days Worked, and Output per Man per Day at Coal Mines in the United States, in 1926*
(Exclusive of product of wagon mines producing less than 1,000 tons)

| State | Net tons | | | | | Value | | Number of employees | | | | Average number of days worked | Average tons per man per day | |
|--------------------------|------------------------------|---|----------------------------------|-------------------------|----------------|---------------|-----------------|----------------------------------|-------------------|------------|---------|-------------------------------|------------------------------|-------|
| | Loaded at mines for shipment | Sold to local trade and used by employees | Used at mines for steam and heat | Made into coke at mines | Total quantity | Value | | Number of employees | | | | | | |
| | | | | | | Total | Average per ton | Underground | | | Surface | | | Total |
| | | | | | | | | Miners, loaders, and shot-firers | Haulage and track | All others | | | | |
| Alabama | 20,008,638 | 671,616 | 269,194 | 51,514 | 21,000,962 | \$ 48,036,000 | 16,140 | 3,378 | 3,506 | 4,321 | 27,345 | 266 | 2.89 | |
| Alaska | 82,000 | 4,450 | 850 | .. | 87,300 | 459,000 | 47 | 8 | 24 | 52 | 131 | 221 | 3.02 | |
| Arizona | .. | 624 | .. | .. | 624 | 1,000 | 1 | .. | .. | .. | 1 | 90 | 6.93 | |

Plans (fig. 28) are shown of a standard practice of mining in the Pocahontas region from an article by Audley H. Stow in *Coal Age*, vol. 3, pp. 594-600.

Another (fig. 34) of the methods of operation of the U.S. Coal and Coke Co. is from an article by Edward O'Toole on the Pocahontas Coal Field, *Proc. A.I.M.E.*, vol. lxxii, pp. 874-897. The

FIG. 28.—TYPICAL POCAHONTAS COAL MINING LAYOUT

plan of concentrated mining of the H. C. Frick Coke Co. and others (fig. 29) is derived from *Proc. A.I.M.E.* vol. lxxiv, pp. 523-536.

Longwall of the circular advancing type has been in operation for many years in northern Illinois, northern Iowa and northern Missouri, also in parts of Arkansas. In general it was adopted only where, as the coal was thin, packwall material was available. Only in quite recent years with the advent of conveyors has longwall been adopted where the coal is of such thickness that rooms can be driven without lifting bottom or shooting top rock and even then but seldom. Room-and-pillar is still standard and almost universal practice where the coal thickness exceeds 4 feet.

Mine Gradients.—In southern Illinois the coal is as level as the prairie land above it, and in much of the United States it is on gradients running from zero to 5%. As the great Appalachian uplift is reached on the east and the Cascades are approached on the west the grades increase. The gentle folds of western Pennsylvania give way to steeper folds in the central Pennsylvania area, grades of 10% being not uncommon. In the anthracite region the coal may pitch at 90 degrees and even turn over so that the rock that was laid down as the roof of the coal becomes what metal miners term the footwall. In the Cahaba and Coosa regions of Alabama, similar conditions exist and in the Cascades also.

There are between the Appalachians and the Cascades some heavy gradients. In Wyoming at Hanna, Gebo, Cumberland, Kemmerer and Rock Springs they have given much trouble. At first it was customary to drive the rooms up the pitch and let the loads pull the empties up to the face of the room, a rope passing over a pulley connecting the two. Friction in some cases had to be used to steady the loads down the grade, and, wood rails being used, speed of travel was further reduced. This method resulted in many accidents to cars and to men. Derailments were frequent, so the method was discontinued at Hanna, Gebo and Rock Springs. In Alabama this system is still being used. In Wyoming it became the custom to drive engine planes down the dip and lay out the rooms on the strike. The loaded cars are drawn by mules to the room mouth and there a rope is attached, the cars being pulled one by one by this rope around the switch or room parting up the engine plane to the level heading above. There the

cars from the various rooms are assembled and pulled by electric locomotives to the main hoist. The mining machines are also lowered or raised on the same engine plane to the rooms which are to be cut. This involves four haulage units—mule, small hoist, locomotive and main hoist—and this does not make for efficiency but the plan seems to be better than the old method. More recently, with the advent of conveyors and scrapers, it has become general practice once again to drive rooms and, sometimes, long faces directly up the pitch, bringing the coal down to level gangways, from which it is hauled by electric locomotives to engine planes, on which it is hoisted to the surface.

Steep grades are also found in Colorado, and in northern Illinois is an extremely steep inclination in a coal bed near La Salle, but this coal is not being mined where the pitch occurs.

Steep Gradient Methods.—Where the pitches are heavy indeed but still light enough for the purpose, it has been customary in the anthracite region to use what is known as a "buggy breast" (fig. 31). The breast or room, is driven up the pitch, and rock is piled in the roadway near the mouth of the room to a considerable depth and to a gradually decreasing depth toward the face so as to reduce the gradient. On the new inclination thus formed a small car or "buggy" is run. This is dumped at the end of the grade into a short chute which carries the coal to a point near the entry where it can be loaded into a standard mine car. The system is used on gradients from 10 to 18 degrees. On lesser gradients the room is frequently turned enough off the pitch to make it possible to place the standard car at the face by mule power.

Where the pitch runs from 18 to 30 degrees, sheet iron is used. Where the coal will not run it has to be pushed or "bucked" with a shovel at great expenditure of human energy. When the coal runs too freely the sheet iron can be omitted and boards laid or the coal may be allowed to run on the coal floor. But with heavier grades the full-battery system is used (figs. 32 and 33). A heavy battery or barricade is erected somewhere, either at the mouth of the room or further in. A chute with a gate at the barricade leads to the car. The coal as it is dislodged is directed to the centre of the room, where it is held by two lines of posts and timber on either side of the centre. It is allowed to fill this space.

FIG. 29.—CONCENTRATED MINING

On either side is a manway which is kept open. Any excess of coal over that needed to fill the battery is let out through the gate, and loaded into cars on the gangway by gravity. The rest of the coal is not loaded till the room or "chute" is driven its full distance up the pitch.

In early days pillars were not drawn. To-day long holes are

FIG. 30.—GENERAL PLAN OF OPERATION OF U.S. COAL AND COKE CO.

drilled in the pillar and the coal shot down or the coal removed in some other way. Sometimes on steep pitches with soft coal, such as the Primrose, the coal will run out of the bed and a steady flow can be taken out at the gate till the roof falls and rock ap-

FIG. 31.—BUGGY BREAST ON 10-18 DEGREE PITCH

pears. The objection to the full-battery system lies in the "degradation," or breaking, of the coal to small sizes and the delay in getting the benefit of a large part of the coal won. In consequence new systems are being put in operation in the anthracite region, notably the slant chute system (fig. 34) used first on a heavy pitch in No. 1 tunnel of the Lehigh Coal & Navigation Co., which, as will be seen, shortens the distance the coal has to travel on the full pitch, arranges for the removal of all the coal and provides that the coal will travel the greater part of the distance

on a slope much less than that of the full pitch (*Proc. A.I.M.E.* vol. 72, pp. 730-734).

The pillars between breasts, whether level or pitching steeply, are often "skipped" (that is, reduced in size by taking off a part up one side) or split by a roadway where the coal pitches slightly or by what is known as a "chute" if the coal pitches heavily. After this the pillar is brought back, but in any event driving these narrow places is expensive, so wherever the pitch is steep the pillar is often entirely removed by the full-battery method, reliance being placed on the coal in the battery to support the roof till the pillar is extracted. This manner of working has been developed into another system, known after the Wanamie Colliery of the Lehigh & Wilkes Barre Coal Co. where it was first used. In the illustrations (figs. 35 and 36) it will be noted that "breasts" are driven with timber and manways on either side.

FIG. 32.—FULL-BATTERY SYSTEM

The Carbon Hill Coal Co. is using what is practically "tailles chassantes," or a stepped longwall face travelling along the pitch in a level direction, the upper end trailing behind the lower, *see* fig. 39. Each miner has his own step, below which is set a wood planking termed a "wing" which protects the miner below and

directs the coal to a chute which carries the coal to a gangway below.

Where in this state badly split seams have to be worked on a steep pitch even more elaborate methods are used. For further details of the methods described and others see Simon H. Ash in the *Proc. A.I.M.E.*, vol. lxxii., p. 833-873.

FIG. 33.—DOUBLE CHUTE BREASTS

Fig. 35 shows the Wanamie method of removing pillars upward from the chain pillar by use of the full battery. Fig. 36 exhibits the means by which the uprise is constructed through the chain pillar. In fig. 37 is illustrated the manner in which, in Pierce County, Washington, narrow "chutes," or rooms, are extended to be drawn back as shown in fig. 38. A longwall method used by the Carbon Hill Coal Co. in Washington is outlined in fig. 39. In many anthracite mines, where pillars have been left in one seam and another seam below it is worked later, rockholes are driven vertically or at a steep angle up to the pillar of the first seam, in which a narrow place is driven till another narrow place is reached from another rockhole. Thus ventilation is provided and the pillar is removed, the coal being dropped or chuted down the rockhole. Much coal in the Mammoth is thus being recovered through the Skidmore bed and the Big Ross through the Little Ross.

Cutters.—Only a few industries in the United States have made equal progress with coal mining in the present century.

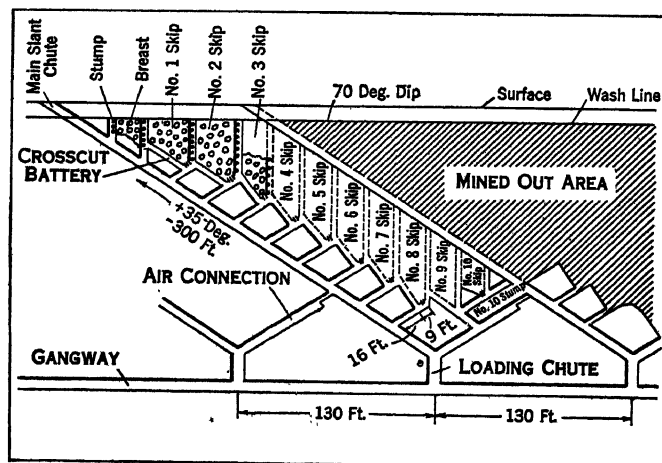

FIG. 34.—SLANT CHUTE METHOD

Very little coal is now undercut by hand despite statistics. In some places the law requires the miner to undercut the coal, but unless it is undercut for him by machine he rarely does more than make a cut of a foot or two and then shoots the coal from the solid. The punching machine, whether operated by air directly, or by air compressed at the machine electrically, has almost entirely disappeared. It cut the coal with a wedge-shaped kerf causing it to fall heavily and roll over so that it was easy to load. All other machines make a uniform kerf and the undercut coal may fall

when shot with scarcely any change in condition. In consequence "snubbing," or converting the uniform kerf into one of wedge shape, is a quite general practice. This work has been done mechanically but not in many mines.

The breast machine, which makes a series of forward cuts under the coal, about the width of the machine and has to be retreated and moved each time a cut is made, still continues to be used, not because anyone prefers it but because such equipment is on hand or can be bought second-hand cheaply and because the wage scale for cutting makes usually no distinctions.

The shortwall cutting machine is provided with chains which enable it to sump its cutter bar into the coal. When it has arrived at the required depth it can be caused to travel across the face cutting the kerf as it goes and stopping only when it has traversed the room or entry. The longwall machine cannot cut itself into the coal but is suited to places where continuous cutting for a long distance is available.

Some cutting machines are mounted on a truck and cut from the rail. They can be adjusted to place a kerf at any desired level. In some mines with fragile roof they cut their kerf near the top of the coal so that the shots can be put near the bottom. In this case the shots must be heavy or they will be less effective than with undercutting and top shooting. In other cases the cut is made in some impurity which it is desirable to remove. In some mines the machine is caused to cut across the face two or more times to remove completely a thick "binder" or "parting" which it is desirable to keep out of the coal. Some machines cut a square kerf and others one that is circular. Machines of this type are made which cut both horizontally and vertically, so that having cut the coal with a level kerf they can cut it vertically or "shear" it as the expression runs. This increases the percentage of "cuttings," or "bug dust," but is said on good authority to so greatly lessen the use of powder that less fine coal results. Plate II., fig. 3 shows a shearing machine.

Longwall machines are made of heights as low as 12 inches. So far no coal is being worked in the United States too low for the operation of a shortwall machine. The track-mounted, or turret,

FIG. 35.—WANAMIE SYSTEM FOR STEEPLY PITCHING COAL

machines require greater height and there are fewer of them in use. Disc machines, like those so common in Great Britain are unknown in the United States. Post punchers, however, have been used. A shortwall machine with a rotary bar armed with cutter bits has been operated in West Virginia for cutting across faces. The introduction of mechanical cutting has been accompanied by mechanical haulage and mechanical drilling. The horse and mule are units of power well suited for "gathering" cars from rooms and entries where the height of the seam is suitable. They can work in gas without hazard. They can go up one room pulling a car, pass through a crosscut to another room and bring out a loaded car, and they often can go through a crosscut from one entry to another and so work conveniently in both. This "flexibility" is absent with electrical equipment which, however, has the advantage of being able to bring more and heavier cars to the parting, requires no food when idle, and is not so readily stalled by adverse gradients.

Haulage.—In 1924 (H. O. Rogers, U.S. Bureau of Mines, in

Coal Age, vol. 32, pp. 84-88) no less than 36,352 animals were still used for underground haulage in bituminous mines. There were also 649 rope haulages, excluding those on main slopes; 779 storage-battery locomotives that can be run with or without trolley current; 1,515 storage-battery locomotives without trolley; 11,986 electric trolley locomotives, 85 compressed-air locomotives, 226 gasoline locomotives, 132 steam locomotives, a total of 14,723

FIG. 36.—DETAIL OF CHUTES IN WANAMIE SYSTEM

locomotives of all kinds. The percentage of coal hauled by animals only in bituminous mines was 10.1; by rope only 0.1; by locomotive only 32.8; by animal and rope 1.9; by animals and locomotives 50.0; by rope and locomotives 1.3; and by animals, rope and locomotive 3.8. This does not include strip-pit coal; 85.6% came from mines using one or more locomotives.

Mine cars are increasing in size, due to the fact that being loaded by machinery the labour of lifting coal to a high car need

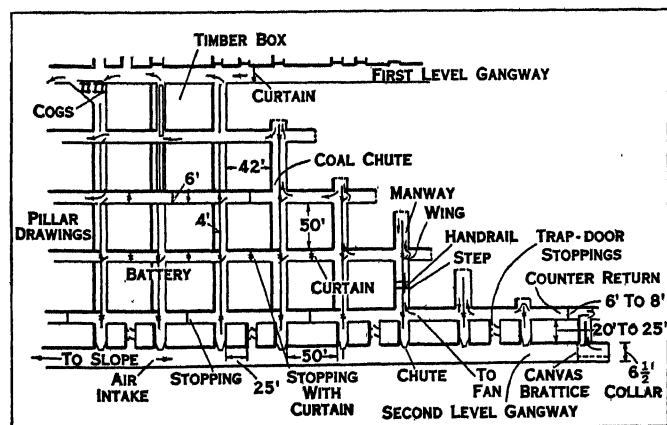

FIG. 37.—CHUTE AND PILLAR SYSTEM. PIERCE COUNTY, WASHINGTON

not be considered, that where large loading machines are provided to get maximum results large receiving units are necessary, that in thin coal a large car can be loaded as readily as a small one, for the loading is done in a high entry, that the haulage units are adequate to handle the biggest cars and that improvements—spring-draft rigging, automatic couplings and bearings—are relatively more economical in weight and cost with a large car. In order to get capacity the body of the car is made wider than the track (which sometimes has as much as 4 ft. 8½ in. gauge). Cars are made as large as 12 ft. long over bumpers, 10 ft. inside length

and 6 ft. inside width. With such wide cars the sides are flared at a low angle or the bottoms are wider than the gauge and the tops of the wheels run in a housing provided in the flared sides or in the bottom.

Coal is often hauled in mines a distance of 5 miles. The H. C. Frick Coke Co. at one point had three shaft mines which were about 4 m. from the Monongahela river, on which lay their Clairton by-product plant. The three mines were combined underground; two rotary dumps were installed each capable of overturning forty 2-1-ton mine cars at one time with a feeding device for delivering that quantity of coal to a 60-in. fabric belt and a series of 18 rubber belts, 48 in. wide, aggregating with the fabric belts 4 m. and 1,810 ft. (Pl. I. fig. 8). The coal is dumped from a cross belt into hoppers over the river.

Another belt line has been built by the same company of a similar character but a little less than 3 m. long with a single 30-wagon underground rotary dump, which delivers the coal that comes from two mines, and a single 2-wagon underground rotary dump which delivers the coal from a third mine. This equipment has a capacity of 12,800 tons per 8-hour day.

For the haulage of large trains big electric locomotives are provided or units are put in tandem. One large electric locomotive weighs 38 tons and develops 399 h.p. from three 500-volt motors. Storage-battery locomotives, locomotives with a cable reel and crab locomotives with a wire cable which serves as a portable hoist are used for gathering. The first two are those most gener-

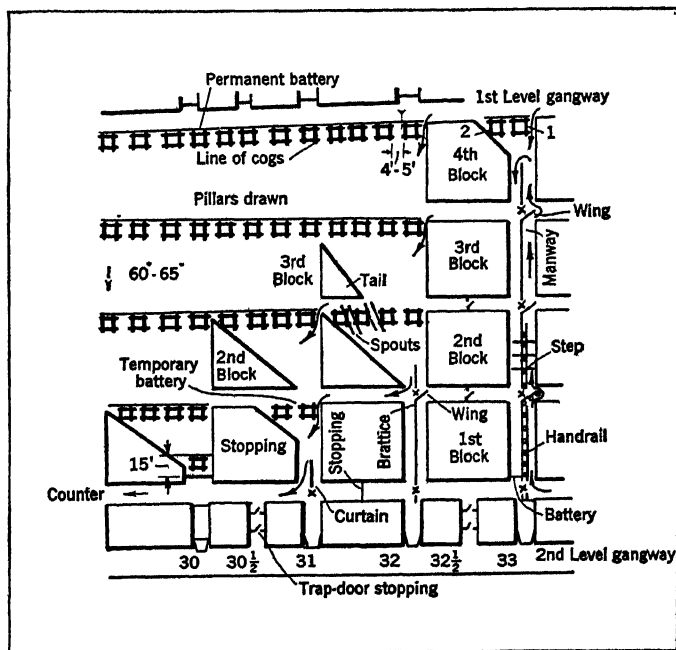

FIG. 38.—WORKING AWAY PILLARS IN SYSTEM SHOWN IN FIG. 37

ally used. For gathering on down gradients room hoists are often provided.

Mechanical Loading.—Last of all improvements is mechanical loading, which in the United States has been liberally interpreted to include both hand-loading into conveyors and loading by machinery into mine cars. Strange to say, the United States had the first conveyor longwall working, namely the Vintondale mine of the Lackawanna Coal Co., in Cambria county, Pennsylvania. The first installation was made by C. R. Claghorn in 1901. After a change in management the longwall face caved, destroying some hundreds of feet of conveyor, and the plan was abandoned, but meantime a large coal area had been worked by this means. Col. Blackett introduced the system into England, and it returns to the United States as a European practice owing to its many years of estrangement. Conveyors are being used in many ways. In some instances they are being operated in rooms 30 to 40 ft. wide. The coal is cut by a machine which is kept in the room and used by the loaders whenever they are ready to prepare the face for shooting. When the coal is shot down part

of it—perhaps a third—falls on a cross conveyor which carries it to the main conveyor, in this instance, a shaking pan (Pl. II. fig. 6), which transports it from the face to the entry, where it is discharged into a mine car. Another third perhaps is pulled down onto the cross conveyor and yet another third has to be shovelled. This shovelling is easily performed because the conveyor is every-

FIG. 39.—STEPPED LONGWALL. CARBON HILL COAL CO.

where near the coal and because the coal need be lifted only a clear height of 4 in. instead of, say, 2 feet. The coal need be shovelled only once whereas with two roads in a 40-ft. room it may be necessary to shovel some of it twice or three times. The cross conveyor consists of a flight conveyor and at the end has what is known as a "gooseneck" which raises the coal a sufficient height to deposit it in the shaking conveyor, into the end of which also some coal falls from the face or is shovelled. Chain-mat conveyors are also used.

In other cases the working place has been made 100 ft. or more wide and the coal has been thrown into a shaking conveyor

FIG. 40.—LONG FACE WITH CONVEYOR (C) OR SCRAPER (I)

running parallel with the face. This dumps into another shaking conveyor, both conveyors being driven by a common unit, the face conveyor being actuated by the main conveyor through a bell-crank attachment. However, frequently the conveyor is situated in front of a long face which may be level or possibly on a pitch (see fig. 40). Where coal is left along the entry, conveyors may be used to receive the coal near the entry pillar and to convey it to the opening through the pillar. Another conveyor then lifts

it into the car. Another provision is the duckbill loader which can be used even where the place being driven is narrow. The differential movement of the shaking conveyor that pitches the coal forward as does a shovel in the hands of a miner is used to enable the duckbill attachment at the end of the shaking conveyor to dig into the coal. As the duckbill has a flaring mouth and wedged teeth it gets under the pile. As soon as the coal is in the shovel-like duckbill it is carried back toward the room mouth. By arranging for the swiveling of the conveyor it is possible to make the duckbill attachment clear a wide area of coal. Little trimming is necessary. Arrangements are provided for feeding the duckbill forward without stopping the equipment.

By putting another shaking conveyor at right angles to the main conveyor with a bell-crank attachment and by transferring the duckbill to this face conveyor, it is possible to have it load off the end of the pillar of the room. This is a valuable aid to safety as the duckbill needs for its manoeuvring only the space occupied by the cut at the pillar end. The system is illustrated by a drawing from an article by Oscar Cartledge in *Coal Age*, vol. xxxiii, p. 473 (see fig. 41). In the West the conveyors in several rooms have been connected with one drive and that also has been done in the anthracite region. Where the pans transmit the motion, each room, perhaps, should have its own drive unit.

Mechanical Scrapers.—Mechanical scrapers were devised by Cadwallader Evans in Jan. 1914. They are well suited to thin coal and are so used for the most part but they are also used on thick coal. Fig. 42 shows an Illinois application (from *Coal Age*, vol. xxxi, p. 428, in which the scraper is used advancing. The loading chute is seen at the mouth of the room and in this instance can be skidded sidewise so as to be available for use in two rooms. The general appearance of a scraper, albeit, small, can be noted in Pl. I. fig. 6. The scoop shovels travel on the floor of the mine and pull from 250 lb. to 5 tons. Where, however, the larger size is used the coal is thick and the scraper is hauled along a face 200 or 300 ft. in length. The retreating method (see fig. 43) is quite generally used. A narrow place is driven up the centre of what will later be the room and when this has reached its boundary the scoop shovel is caused by diagonal cuts to widen the working place to the required width. As the work is retreating, no pillar or only a foot or so has to be left, this being to prevent fallen roof rock in the advance room from being loaded by the scraper in the adjacent room. The scoop shovel gathers the binder or partings with the coal and sometimes, when the bottom is soft, scrapes up the bottom clay, especially if there are rolls. For this reason the scraper is used only in coal that is reasonably free of irregularities.

Short inclined elevating conveyors have been designed for hand loading. The upper end of these inclined conveyors is high enough to load into a mine car. The lower end rests so near the floor as to make loading easy. This type of conveyor can be moved around either on a track or on the floor. In some instances it has a self-propelling truck and power-driven capstans for handling the mine car back of the loader.

A large number of conveyor loaders has been designed and used that pick up their own coal and pass it by a conveyor to another swiveling conveyor that discharges the coal into a car. The main difference between them is in the means by which the coal is lifted from the bottom. One well-known machine has gathering arms which pull the coal onto an inclined conveyor. Most types rely on the conveyor itself to do its own gathering.

FIG. 41.—DUCKBILL LOADING ON END OF PILLAR

The conveyor in one type has a chain, working on sprockets with vertical axes, which sweeps the coal onto and up an inclined trough. Others have vertical sprockets and the flights being buried in the loose coal lift it onto the conveyors. One such conveyor has loaded an average of 466 tons from room and entry faces in eight hours over a period of a month. Another shortwall machine combines cutting and loading. It cuts the coal, which is then

FIG. 42.—SCRAPER DRIVING ROOM

shot down. The machine is sumped again into the loose coal and fed as for undercutting, but for this part of the service two other bars like the cutting bar but shorter are provided. They, with the cutter bar, drag out the coal and force it onto the flights of a conveyor.

Another quite recent machine is only 26 in. high. It has only one conveyor chain working on sprockets with vertical axes. This conveyor not only lifts the coal from the floor but places the coal in the mine car or a room conveyor, the conveyor itself being so arranged that one end can be swiveled. The intention, however, is not to bring the mine car to the loading machine but to have the loader dump into a portable shaking conveyor running on the room rails with the loading mechanism of this conveyor serving (1) as a flight conveyor to lift the coal from the conveyor to car height, (2) as a car feeder to spot a line of cars in front of the loading chute at the entry as desired and (3) as a locomotive to haul the conveyor from room to room.

Another type of loader is a power shovel that is forced under the coal and lifted. The shovel has no back and consequently the coal falls off the rear of the shovel onto a conveyor, by which it is conveyed to the swiveling conveyor which drops it into the mine car. This has been modified so that where the first conveyor can be loaded by the advance of the loader without a movement of the shovel the equipment can be used in this manner. Another type of shovel loader has a hydraulic pillar which bears against the roof and around which as a trunnion the whole equipment turns a full circle of 360 degrees if necessary. The shovel is forced under the coal pile and withdrawn. It is then lifted and swung over the mine car, whereupon it is emptied by an ejector plate.

For heading-driving, one machine is provided with an undercutting bar and two shearing cutters with a number of picks which break the coal down, which then falls and is removed by an inclined conveyor. Another machine has two revolving cutters that cut two interlapping tunnels in the coal with a chain that cuts the top and bottom. It makes an entry 11 ft. wide and about 6 ft. high with flat roof and floor line but with sides which are segments of circles.

Stripping Methods.—Open-cut mining is the term applied to

the working of mineral deposits which either outcrop at the surface of the ground or are covered by a shallow overburden or capping, which must be removed before the ore can be mined. In coal mining work mining by this means is generally termed stripping. Since the cost of removing the overburden is charged to the cost of mining a point is reached, as the cover increases in thickness, beyond which open-cut mining does not pay and some method of underground mining must be used.

One of the most distinctive features of open-cut methods in American coal mining, one that probably cannot be found in any other country or in any other type of mining in the United States or elsewhere is the method of stripping by casting. There are many strippings in the United States where the overburden is loaded by shovels or drag line excavators into cars, hauled to a distance and dumped. This is the most usual way of uncovering mineral in Europe and in America. Large machinery is sometimes used, as at Yallourn in Australia, where one 370-ton shovel, one 200-ton shovel and one 150-ton shovel with respective bucket capacities of 9, $3\frac{1}{2}$ and $2\frac{1}{2}$ cu.yd. are installed, and Hazleton, Pa., where a 6-cu.yd. shovel weighing 230 tons is being used. Here the maximum cover to be removed is 165 feet.

In Yallourn, conveyors are used instead of cars but the usual American method is entirely different. If the coal outcrops, the cover is lifted off the coal in a long swath 100 or more feet wide by a steam or electric shovel or drag line excavator and dumped down the hill. If the coal does not outcrop, the cover is similarly lifted from the coal and deposited along the property line. A smaller steam or electric shovel follows the stripper and lifts the coal into mine cars which carry it to the tippie. Where the coal occurs in a knob or small hill the two shovels chase each other round the hill, the stripper uncovering the coal and depositing the spoil where the coal has been removed by the coal shovel. In this manner none of the overburden is moved more than 100 to 125 ft., and it is all done without the use of cars or conveyors. The cars are used solely for transporting coal. As much overburden as

FIG. 43.—LAYOUT FOR SCRAPER RETREATING SYSTEM

10 or 12 times the thickness of the seam being worked has been removed. In rare instances as much cover as 70 ft. has been taken but the difficulty of finding space for the spoil and the disadvantages in making such big cuts limit the overburden taken even with thick coal. At Forsyth, Mont., where the coal is lignite and extremely thick, the coal output per man employed is 47 tons. The largest shovel employed for such stripping is that of the Northern Illinois Coal Corporation, near Wilmington, Ill. This special shovel has a 12-cu.yd. dipper on a 90-ft. boom and a 60-ft. dipper handle.

In 24 hours it has handled 15,481 cu. yards. The United Electric Coal Companies has ordered a 15 cu.yd. shovel for stripping that will take at one bite 7×7×8 ft. of spoil. The boom will be 120 ft. long and the dipper stick will be 82 ft. long. Its reach will be over 150 ft. and it will lift material 90 to 100 ft. The coal stripped by steam or electric shovel is often only 24 or 30 in. thick.

Regulation and Inspection.—Owing to the many States in which mining is pursued and in part to the varied conditions in each State and to the differences in their accident records, the laws vary greatly and, as some think, unduly. The anthracite and bituminous mines in Pennsylvania have entirely separate laws. Each State has its own inspectors and some have both State and county inspection. The U.S. Bureau of Mines is almost solely a research body. It had at one time regulatory power over properties in the segregated Indian lands and in the areas mined under lease from the U.S. Government. The authority has recently been transferred to a division of the U.S. Geological Survey.

The bureau has examined and approved several explosives and several types of mining equipment which it has declared "permissible," the word "permitted" not being used as in Britain, because the bureau has no power to admit or exclude explosives or equipment under the U.S. Constitution. The bureau has established mine rescue stations and equipped cars for the same purpose, and these are used most effectively for the saving of life in the larger mine disasters. (R. D. H.)

COALBROOKDALE, a village and ecclesiastical district of Shropshire, England, on the G.W.R., 5 m. S. of Wellington. Pop. 1,400. The "dale" is the valley of a stream rising near the Wrekin and following south-east for about 8 m. to the Severn. Its ironworks, founded in 1709 by Abraham Darby with Dutch workmen, were the pioneer attempt to use pit-coal for smelting iron.

The third Abraham Darby built the famous Coalbrookdale iron bridge over the Severn, which gives name to the neighbouring town of Ironbridge, which with a portion of Coalbrookdale is in the parish of Madeley (*q.v.*). There are also brick and tile works.

COALDALE, an anthracite-mining borough of Schuylkill county, Pennsylvania, U.S.A., 45 m. S. by W. of Scranton. It is on Federal highway 209, and is served by the Central railroad of New Jersey and the Lehigh and New England railroad. The population in 1930 was 6,921, of whom 1,703 were foreign-born white.

COAL-FISH (*Gadus virens*), a fish of the cod family, with three dorsal and two anal fins, distinguished from the cod by its blackish colour, prominent lower jaw, and very small barbel. It ranges from the Arctic ocean to the Mediterranean, and grows to a length of about 4 feet.

COALING STATIONS: see FUELLING STATIONS.

COALITION, a combination of bodies or parts into one body or whole. (Lat. *coalitio*, from *coalescere*, to grow together.) The word is used, especially in a political sense, of an alliance or temporary union for joint action of various powers or states, such as the coalition of the European powers against France, during the wars of the French Revolution; and also the union in a single Government of distinct parties or members of distinct parties.

COAL TAR, the viscous, oily fraction of the liquid distillates obtained in the manufacture of coal-gas or of coke by the destructive distillation (see CARBONIZATION) of bituminous coal at 900–1200° C. Many factors affect both the yield and composition of the tar, particularly the class of coal carbonized, the type of retort setting used, the temperature at which the coal is heated and the manner in which the heat is applied. The tars obtained when coal is distilled in horizontal retorts for the production of either gas or coke are sufficiently similar to be classed under the heading of coal tar.

In the manufacture of gas, the coal is often mixed with bog-head shale, bituminous lignite, etc., the gas being thereby enriched. The tar is, however, of less value, being mixed with paraffins, which make the purification of tar products much more difficult. Also, by the substitution of vertical for horizontal retort settings, a tar is obtained which differs in some respects from ordinary coal tar. This new tar is thinner owing to the presence of paraffinoid substances, contains a higher percentage of tar acids,

and on distillation yields much less pitch (40–55%) than tars from horizontal retorts. The yield of tar from vertical retorts is slightly higher, and the amount of "free carbon" (*i.e.*, residue insoluble in benzene) is much smaller. These variations from "normal" tar are due to the fact that many of the products of distillation are removed from the reaction chamber before the coal has reached its final high temperature. Vertical retort tar, therefore, has some of the characteristics of low-temperature tar (see TARS, LOW-TEMPERATURE). Owing to the increasing use of vertical retorts, two types of tar have to be considered as commercial products. The effect of temperature of carbonization on the yield and composition of tars is very marked. The product commercially accepted as coal tar is therefore that derived from the carbonization of bituminous coal in horizontal retorts at 900–1200° C, where the primary object is the production of coal-gas or coke. In either case the tar is a by-product of the operation.

Properties and Composition.—Coal tar, a thick, black, oily liquid of sp. gr. 1.1 to 1.25, is obtained with ammoniacal liquor when the volatile products of the carbonization of coal are cooled. On settling, the distillate separates into two layers, and the aqueous ammoniacal liquor is drawn off from above the tar. The latter, however, mechanically retains approximately 4% of aqueous liquor which is very troublesome in subsequent distillation. The average yield of tar is 10 gals. per ton of coal carbonized, or 5% by weight. All tars contain so-called "free carbon," which, although resembling amorphous carbon, always contains hydrogen. The constituents of coal tar are almost wholly aromatic in character, comprising hydrocarbons of the benzene, naphthalene and anthracene series, oxygenated compounds including carboxylic acid, the cresols and cumarone, nitrogenous substances, mostly basic and belonging to the pyridine and quinoline series, and in lesser degree compounds containing sulphur, *e.g.*, thiophene. Small amounts of members of the aliphatic series are, however, never absent, paraffins, acetone, acetonitrile, carbon disulphide and other representatives of the "fatty" series being usually identifiable. Several hundred entities have been identified in tar, less than 200 have been estimated, and not more than 100 have been isolated; commercially, it is profitable to isolate in the pure state only a few of these.

The most general characteristic of tar is the occurrence in it of naphthalene, which may represent as much as 10% of the crude tar and is the predominant constituent. Other constituents are benzene, anthracene, phenanthrene, carbazole, acenaphthene, fluorene, carboxylic acid, cresols, pyridine, quinoline, isoquinoline and cumarone; the amount of any one of these substances rarely exceeds 1%. Valuable as these pure compounds are, from an industrial and commercial point of view, as distinct from that of the organic chemical industry itself, the various crude products obtained from tar are of equal if not greater importance. These coal tar "crudes," including the benzols, toluols, solvent naphtha, heavy naphtha, cresylic acid, creosote, heavy bases, anthracene oil and pitch, form the various "fractions," or can be easily prepared from these fractions, when the tar is distilled.

Distillation.—Whether crude or refined products are required, straight distillation is the industrial method of dealing with the crude tar. It is very seldom, however, that all the above fractions are collected in any one distillation, the crude products required being dependent on fluctuating demands or on the particular purpose for which the tar is distilled. Thus if tar for road making is the object, the anthracene oil fraction is not collected but left in the still with the pitch. Again the crude benzols boiling up to 110° are sometimes collected separately instead of being run with the light oil up to 180–200° C. In a preliminary distillation of tar the following fractions are usually collected:—

- (1) Crude naphtha (first runnings), boiling point up to 110° C.
- (2) Light oil, b.p. 110° to 180–200° C.
- (3) Crude carboxylic oil or light creosote, b.p. 180–200° to 240–250° C.
- (4) Heavy creosote, b.p. 240–250° to 270–280° C.
- (5) Anthracene oil, b.p. 270–280° to 340–350° C.
- (6) Pitch.

These fractions are more or less standard, but rearrangements in the cutting points are to be expected as research develops new applications for substances such as acenaphthene, fluorene, acridine,

etc. The value of cumarone and indene as resin-forming constituents is a case in point. To obtain a fraction rich in these two substances, a distillate b.p. 160–180° C is isolated.

Dehydration of Tar.—The presence of aqueous liquor leads to many difficulties in the distillation of tar, especially “frothing” and “bumping.” Although many efforts have been made to dehydrate the tar before distilling it, prolonged, gentle heating is the only method which has been found satisfactory. For this purpose steam is supplied through a series of closed coils immersed just below the surface of the liquid. By regulating the supply and controlling the level of the tar, the process is made continuous, and dry, heated tar overflows for use in any distillation apparatus.

In cases where no special preliminary dehydration of the tar is carried out, special mechanical and heating devices are used during the distillation of the light oils and water. A typical tar distillation plant is the Woodall-Duckham still (*see* DISTILLATION).

The tar, separated from excess of aqueous liquor by long settling, is charged into the still and heat applied either by means of coal or (as in coke-oven installations) of surplus gas, which permits of very delicate heat control. In all distillations, unless the tar has been previously dehydrated, the first runnings consist of a very light oil and water which separate on standing, the oils forming the upper layer. When no more water distils—a point usually coinciding with the rise of the specific gravity of the oils to 1.0—the crude carbolic oil is collected, and at this stage the condensing apparatus must be maintained at 40° C to avoid deposition of naphthalene in the coils. The end point of the carbolic acid fraction is denoted by the appearance of the distillate, which runs more freely as the naphthalene content decreases. The anthracene oil fraction is collected when the distillate assumes a green colour or when “green grease” makes its appearance, the condensers at this point being maintained at about 100° C. The pitch is run out of the still whilst hot. Towards the end of tar distillations much trouble is often caused by “coking.” To prevent this, and also to help in the distillation of the higher-boiling fractions, use is often made of direct superheated steam and of reduced pressures. These modified methods also improve the yield and quality of the distillates, particularly of anthracene. The temperatures of fractionation are seldom controlled by thermometers, but use is made of the specific gravity, appearance, or volume of the distillates. The end point of the operation is determined, not by temperatures, but by the class of pitch required or the total volume of distillate obtained.

Working Up of the Fractions.—Fraction I. (first runnings), representing 1.5–2% of the crude tar, after separation from the aqueous liquor which has accompanied it in the distillation, consists of a mobile oil of sp.gr. 0.89 and is composed mainly of benzene and toluene with small amounts of phenols and bases. The products of commercial importance isolated from this fraction are pure benzene and toluene and the crude distillates, “90% benzol” and “50% benzol.” The first step in the purification of the oils consists in washing them thoroughly with caustic soda solution (10%) whereby the acidic (phenolic) constituents are extracted as sodium salts soluble in the aqueous solution. A similar extraction with dilute sulphuric acid removes the bases as soluble sulphates. If the ultimate aim is the production of pure constituents, the oils at this stage are agitated with concentrated sulphuric acid, impurities such as olefines and nitriles being destroyed. Successive treatments with alkali and water render the oils neutral. The alkaline and acid washings from this fraction are added to the similar extracts from the light oil and the carbolic oil. The neutral oils, before treatment with concentrated sulphuric acid, consist almost entirely of benzene and toluene, although small quantities of olefines, paraffins, nitriles, carbon disulphide and thiophen are usually present. A further stage in the purification of the oils consists in fractional distillation with or without the aid of direct steam. By careful fractionation and the use of efficient rectifying columns, almost pure benzene (*q.v.*) and toluene (*q.v.*) can be obtained. The yields of these hydrocarbons from this and the next higher fraction are approximately 0.4 to 0.6% and 0.2 to 0.4% respectively calculated on the crude tar. In many cases the pure hydrocarbons are not isolated, fractions

designated as “90% benzol” and “50% benzol” being collected. (The expression “per cent.” in this case signifies that 90%, or 50%, distils below 100°.) Commercial 90% benzol contains about 70% benzene, 24% toluene, traces of xylenes and 4–6% carbon disulphide, light paraffins, etc.; 50% benzol is chiefly toluene and xylene with a small proportion of benzene.

Fraction II. (light oil), consisting of hydrocarbons, mostly homologues of benzene, together with phenol and pyridine, amounts to 7–8% of the tar. By application of the treatment described in the case of fraction I, this fraction may be made to yield the pure hydrocarbons, toluene, *o*-, *m*- and *p*-xylene (0.2 to 0.5%), pseudocumene, and mesitylene, or alternatively the crude fractions 50% benzol, 30% benzol, solvent naphtha and heavy or burning naphtha. Solvent naphtha, consisting of xylene and higher homologues, with naphthalene and paraffin in small quantity, is that fraction of the neutral oils distilling between 120° and 160° C, whilst heavy naphtha, containing mostly pseudocumene, mesitylene, naphthalene, with smaller amounts of cumarone and indene, distils between 160° and 190° C.

The acid extracts from fractions I. and II. are worked up for basic compounds. The bases obtained from these low tar distillates are principally of the pyridine series, contaminated with a small quantity of aniline and resinous products. The two latter are removed from the solution of the sulphates of the bases by fractional precipitation by ammonia and the bases subsequently liberated by the addition of aqueous caustic soda or ammonia. The crude bases separating as a black oil are collected and distilled over solid caustic soda in iron stills. Pyridine to the extent of 0.1% of the tar forms the major part of these bases, but methylated derivatives of this constituent are also present.

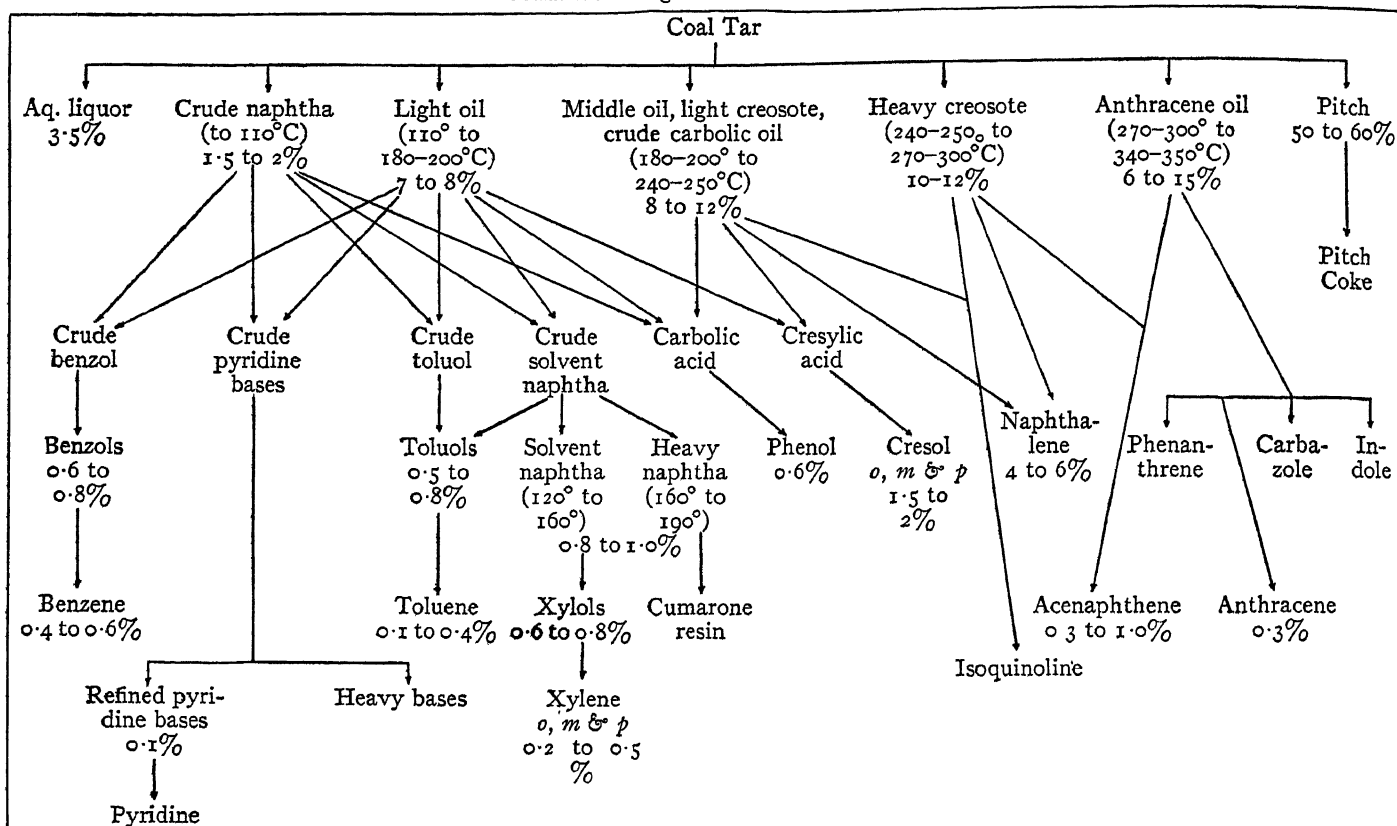

Fraction III. (crude carbolic oil or light creosote) is one of the most important fractions of the tar of which it represents 8 to 12%. Its major constituents are naphthalene, which may amount to as much as 40% of the fraction, and the lower phenols, carbolic acid and the cresols. At ordinary temperatures it is solid or semi-solid with a specific gravity of 1.2, but at 45° C is wholly liquid. The oils are chilled and the naphthalene, of which about four-fifths crystallizes out, is isolated by filtration or by exuding the oil under hydraulic pressure. Further purification of this hydrocarbon consists in treating the melted product with concentrated sulphuric acid and caustic soda, followed by distillation or sublimation. The content of naphthalene, by far the largest single constituent of the tar, varies from 6 to 10%.

The oily filtrate from the crude naphthalene, containing phenols, cresols, xylenols, pyridine bases and dissolved naphthalene, is called crude carbolic acid. It contains 25–35% of phenols and 5% of bases. The former are extracted in the manner described in the purification of fraction I., and the alkaline solution with the corresponding extracts from fractions I. and II. are steamed to remove neutral substances and then decomposed by means of mineral acids or carbon dioxide. The phenols, which separate as an oil, are collected, washed with water and distilled, when crude carbolic acid, b.p. about 180° C, is separated from the cresols (*q.v.*), xylenols and higher phenols, the mixture of which is termed liquid carbolic acid or cresylic acid. Repeated fractionation of crude carbolic acid finally yields a pure white product which crystallizes on cooling after distillation.

The oils left after extraction of the phenols can be worked up for pyridine bases, naphthalene and heavy solvent naphtha in the following manner. Agitation with sulphuric acid extracts the bases, which can be recovered as described above, whilst the remaining neutral oils are chilled and filtered, a second yield of naphthalene being thus obtained.

Fraction IV. (heavy creosote), a greenish-yellow, fluorescent oil amounting to 10–12% of the tar, contains carbolic acid, cresol, naphthalene, anthracene and other hydrocarbons, and is employed in the crude state as creosote oil. The naphthalene content in this fraction may be as high as 20% and the hydrocarbon often crystallizes out on standing. It is removed by distillation, being found in the first runnings of the distillate, from which it crystallizes in a pure condition. The crude oily residue of the oils containing nearly 30% of high phenols is employed in commerce without

Crude Coal Tar Distillates as obtained in practice and the Refined and Pure Products Derived therefrom
Yields are average values on the crude tar

further purification. The "creosote oil" contains several constituents which are of increasing importance.

Isoquinoline (*see* QUINOLINE) is obtained from the mixture of crude quinoline bases which are extracted from the creosote oil by sulphuric acid. Its purification, a matter of some difficulty, consists in fractional precipitation of the crude bases with ammonia, and the conversion of the most basic components into sulphates, followed by crystallization of the sulphate most insoluble in alcohol until the m.p. rises to 206° C. Decomposition of this sulphate liberates the pure base, b.p. 242° C.

Indole (*q.v.*), extracted as its potassium salt when the neutral oils of the creosote fraction are heated with solid caustic potash, is liberated when the potassium salt is treated with water, and purified by distillation under reduced pressure.

Acenaphthene (*q.v.*) appears in the creosote fraction distilling at 260-270° C. On cooling, this fraction yields a solid product moderately rich in hydrocarbon. Further purification is carried out by crystallization from alcohol.

Fraction V. (anthracene oil or green oil), which represents on an average 12% of the tar, is wholly liquid at 60° C, but on cooling to ordinary temperatures it becomes semi-solid, yielding a crystalline deposit of crude anthracene amounting to 6-10% of the fraction. This crude product is freed from oils by centrifugal plant or by hydraulic or filter presses. After pressing, first cold then hot, a crude anthracene cake containing 30 to 40% of anthracene is obtained. Other hydrocarbons present in this crude product include methylanthracene, phenanthrene, acenaphthene, diphenyl and pyrene, whilst nitrogen compounds such as carbazole and acridine are also present. As a general rule phenanthrene and carbazole (*q.v.*) are the chief constituents together with anthracene in the crude filtered product. These three substances can be separated by treatment first with naphtha, which dissolves the phenanthrene, and then with pyridine, in which carbazole is much more soluble than anthracene (*q.v.*). The latter is then purified by sublimation.

From the anthracene oil fraction, by treatment at 280° C with solid caustic potash, the hydrocarbon fluorene (*q.v.*) can be isolated through its potassium salt, which is freed from oils and

other hydrocarbons, and decomposed by means of water. The accompanying chart (Bunbury and Davidson) illustrates the preliminary distillation of tar and the nature and average yield of the commercial products.

APPLICATIONS

Refined Products.—The constituents of tar isolated in the pure state and used as such in chemical industry, usually as starting points for the manufacture of other chemical compounds, are benzene, toluene, naphthalene, phenol and anthracene; in lesser degree, the xylenes, cresols, pyridine, acenaphthene, phenanthrene and carbazole; and to a smaller extent still, indole and isoquinoline. These substances together only amount to some 10% of the tar, and of this naphthalene forms the major portion. Synthetic methods of manufacture are reducing the demand for even these few tar products. Thus the synthesis of anthraquinone (*q.v.*) has rendered unremunerative the extraction of anthracene from the tar. Synthetic phenol, being superior in quality to that derived from crude carbolic oil, will gradually reduce the demand for the latter, provided a sufficient supply of benzene is available. The tendency, therefore, is to find some utilization for those constituents of the tar which can be isolated without undue difficulty.

Although the number of pure products isolated commercially is small, their value can hardly be assessed. Many industries are largely dependent on these few substances either directly or indirectly. In fact, the majority of the industrially important organic chemicals are prepared from the five first-mentioned constituents of tar. Naphthalene is one of the main starting points in the manufacture of intermediates for the important dyestuff industry, whilst from anthracene springs the whole of the anthraquinone series of vat colours and also the mordant dyes of the alizarin group.

The pharmaceutical use of coal-tar products takes its place in the front rank, not so much because of the amount of material used, which is comparatively small, but on account of its importance in the prevention and suppression of disease. As antiseptics, antipyretics, hypnotics, anaesthetics, etc., the derivatives of benzene, toluene and phenol particularly have received wide and

successful application. Further, the growth of synthetic organic chemistry from coal-tar products has enabled the medical profession to fight a winning battle against bacteria and trypanosomes. The value of these specialized applications of tar products lies not in finance or in economics but in their significance in human affairs.

Toluene and phenol are respectively the starting points for two well-known explosives, T.N.T. and picric acid, whilst the World War led to the manufacture of lachrymators ("tear gas"), such as diphenylchloroarsine, designed to produce disablement. In the manufacture of these, large quantities of benzene, toluene and phenol are used.

Another important industrial development is the manufacture of synthetic resins (*q.v.*), wherein large quantities of phenols and cresols are used in one type of resin and cumarone and indene in another.

Derivatives of tar products have had successful application as rubber accelerators, particularly nitrosophenol, aniline and nitrosodimethylaniline.

The manufacture of perfumes, the photographic industry, and the synthetic organic chemical industry employ large quantities of the pure constituents of coal tar. An interesting development is the manufacture of hydrogenated naphthalenes and phenols which are powerful solvents, especially for fatty oils, waxes, gums, resins, etc. One of the most important properties of hydrogenated phenols is their power of dissolving or dispersing in aqueous soap solutions, yielding a colloidal solution with powerful detergent and emulsifying powers. They are used in soaps, pastes and polishes, and in certain varnishes and lacquers.

Crude Products.—In addition to the value of the pure constituents isolated from the tar, there are products obtained by distillation which have far-reaching technical and industrial uses, and which are consumed in quantities many times greater than all the pure products combined. The coal-tar industry is indeed dependent on the commercial usefulness of the "crudes," *i.e.*, the distilled fractions and the residue, which together amount to 90% of the tar. The following are some of the most important applications of tar and its crude distillates.

(1) *Crude Tar.*—Commercial application of crude tar is somewhat restricted, as in most processes the presence of water is detrimental. In the crude state, however, tar is used as an anti-corrosive paint in the protection of iron, wood, brick and stone work against atmospheric conditions. This application is particularly useful in large manufacturing works where iron-work is exposed to an acid atmosphere. As a preservative, the crude product is used in the tarring of ropes and other accessories in ships. By the application of the Bergius process of hydrogenation (*q.v.*) tar, when heated with hydrogen at 430° C under 100 atmospheres pressure, is converted into a product resembling petroleum, 60% of which distils below 250° C and from which fuel oils and spirits can be obtained by distillation.

(2) *Prepared Tars.*—By far the widest application of tar is in the surfacing of roads and binding of macadam, granite chips or wood blocks. For this purpose the crude tar is "prepared" by distillation up to the point when the creosote oil begins to distil. The residue in the still, consisting of pitch dissolved in the heavier oils of the tar, constitutes road tars. Prepared tars, or tars from which the water and more volatile oils have been removed, can be regarded as soft pitch. These may be diluted further with distilled creosote and are often mixed with asphalt, mineral pitch or bitumen to improve the binding power. In tarring stones about 10 gal. of tar are used per ton of stone, and in surfacing 1 gal. covers about 6 square yards. Prepared tars are also used in the manufacture of steel linings for converters of the Bessemer type, and in the manufacture of roofing felt, when the woollen fabric is impregnated with the hot material and covered with a layer of sand on both sides.

(3) *Pitch.*—In the distillation of tar the residue in the still is pitch, constituting from 50 to 60% of the original tar. Until the modern demand for road tar developed, this pitch formed the most valuable fraction of the tar commercially. It is used chiefly as a binder for small coal in the preparation of briquettes, the

proportions used being approximately 90% of coal and 10% pitch. Some of the more important specifications for pitch for briquettes are: softening point not to be below 60° C, amount of "free carbon" not to exceed 30% and absence of excessive amounts of volatile matter. In the preparation of briquettes, the coal slack is "wetted" with molten pitch and compressed into uniformly shaped blocks which are resistant to ordinary handling and transport. Mixtures of coal and pitch or the coke formed by the carbonization of the pitch have been used as domestic fuel. These products are attractive by reason of their low ash content and the high radiant heat obtained on combustion.

Pitch is often used as one of the components in protective paints and varnishes. For this purpose it is dissolved in heavy naphtha, other ingredients such as creosote being added as desired. A special bituminous paint is made by heating pitch to 160° to 200° C and adding cumarone resin as a solvent; a waterproof paint consists of a mixture of 1 part of pitch, 1 part of hot tar, and a suspension of 1 part clay in 1 part of water.

Other minor applications of pitch are the production, by further carbonization, of a coke suitable for the manufacture of electrodes, and as a filling material for resins in the manufacture of cold moulded articles.

(4) *Crude Benzols.*—The neutral oils of tar distillate up to 110° C constitute the commercial "crude benzol." For employment as a motor fuel it is further purified by redistillation and careful fractionation, eliminating the carbon disulphide which distils in the first runnings. If a high-grade fuel is required, the thiophen, which cannot be separated from the benzene by distillation, is removed by treatment with concentrated sulphuric acid. Motor benzol gives a ton-mileage per gallon 25% higher than petrol and has other advantages, such as less tendency to knock, whilst allowing a higher compression ratio to be used. It is also used in admixture with petrol, the fuel being known as "benzole mixture." Motor benzol has the following properties. Its sp.gr. is 0.87–0.885, and on distillation not more than 75% should pass over below 100° C and 90% below 120° C, whilst at 125° C there should be no residue. The sulphur content does not exceed 0.4% and the product is water-white in colour and free from water. It is free from acids, bases and sulphuretted hydrogen, does not freeze above –14° C, and when shaken with 90% sulphuric acid for 5 minutes does not give more than a light brown colour in the acid layer.

As a solvent, the crude benzol is used extensively in the paint and varnish trade, and for dry cleaning. Mixed with acetone it dissolves nitrocellulose, and with anthracene oil it is used as a solvent for resins. Purified benzol is one of the most important solvents used in fine organic chemical work. It is also used as a fuel in heating lamps and blow-lamps.

(5) *Solvent Naphtha*, as its name implies, is almost wholly used as a solvent. It also dissolves paints and varnishes and is used extensively in the composition of grease and oil removers.

(6) *Heavy Naphtha.*—High boiling, heavy or burning naphtha contains two substances, cumarone and indene, which when treated with suitable reagents polymerise to form valuable resinous products. In the manufacture of the resins (*q.v.*) the pure compounds are not isolated, the crude naphtha, b.p. 160–180° C after purification, being used. This crude distillate is also employed as a fuel for burning in illuminating lamps of the Lecigen type for use out of doors.

(7) *Anthracene Oil.*—After removal of the crystalline deposit of anthracene, the green oil is used, like creosote, as a fuel in Diesel engines and as an absorbent in gas washing. It is also employed as a lubricant for clay moulds in brick making, and as a component in grease for lubricating wire ropes such as are used in mines, ships, etc.

(8) *Light Creosote.*—Large quantities of light creosote, generally in the form of cresylic acid, are used in the preparation of general disinfectants, sheep dips and timber preservatives. It is usually profitable to extract the carbolic acid from the light creosote by using insufficient alkali to neutralize all the phenols in the fraction. The "sharp oil" or cresylic acid which remains is the basis of many common disinfectants. Saponified by emul-

sifying agents it is found in commerce under the trade names of "Lysol," "Creolin," etc. When dispersed in water, these products are powerful disinfectants and are used for general purposes.

(9) *Creosote Oil* or heavy creosotes have provided excellent fuels for oil-burning engines of the Diesel and semi-Diesel type. These oils have a high ignition temperature, approximately 450–500° C, and difficulties are met in starting the engine from the cold. Two methods have been used to overcome this difficulty—either starting the engine on a low fuel such as petrol and changing over to the higher fuel when the engine is sufficiently hot, or using a mixture of 10% petrol and 90% creosote as fuel. Creosote for this purpose must be thoroughly freed from solids such as naphthalene, inorganic salts and tarry impurities. It also forms a good fuel for oil-burning furnaces such as are employed in glass works and in heating rivets and small metal work. Like naphtha it is burned in lamps for out-door use.

Heavy creosote is also used as an absorbent in the recovery of light hydrocarbons from coal gas. In this process, called "gas washing" or "gas stripping," the gas is made to ascend towers down which the heavy oil is sprayed. The absorbed light oils, consisting chiefly of benzene, toluene and xylene, are recovered by subsequent distillation and amount to 1 to 3 gal. per ton of coal fivefold by creosoting.

Creosote finds its largest application in the preservation of wood, especially railway sleepers, piles, telegraph posts and paving blocks, being frequently applied under pressure, sometimes after subjecting the timber to a vacuum. The oil may also be used at a temperature sufficient to boil the sap out of the wood. The advantages of treating wood with creosote are the closing of pores, thus rendering the material a non-absorbent of water, the inhibition of germ life, and the coagulation of albumen by the tar acids. It is estimated that the life of railway sleepers is increased fivefold by creosoting.

Heavy creosote, after elimination of deposited naphthalene, is frequently converted into general disinfectants by admixture with about four times its volume of slaked lime, when "disinfectant powder" is obtained. This is used for railway cars, farm buildings, etc. When saponified by soaps, these oils form disinfecting emulsions with water and are used as sheep dips. Being less caustic than carbolic acid, the tar acids of the heavy creosote are less harmful to animals (*see TARS, LOW-TEMPERATURE, for wood-tar creosote*).

Creosote has been suggested as a soil sterilizer. A direct conversion of creosote oils into permanent gas has been evolved, but high temperatures are necessary. A ton of oil is capable of yielding 13,000 cu.ft. of gas of 14 candle power. Sulphonation products of light and heavy creosotes, either alone or on further condensation with formaldehyde, have been used as tanning agents.

(10) *Crude Tar Acids*, i.e., the phenolic substances found in the higher fractions of the tar distillates have been applied as froth-producing agents in the "froth flotation" process, which mechanically and economically separates associated solids such as coal and stone, ore and earth, etc.

(11) *Pyridine Bases*, and more particularly crude pyridine, are used as denaturants to make alcohol non-potable. They are also employed as solvents, notably in the purification of anthracene.

(12) *Crude Solid Aromatic Hydrocarbons*.—The sulphonated products of crude phenanthrene, fluorene and carbazole have been applied as tanning agents. More extensive use has been made of crude naphthalene. It is claimed that a solution of naphthalene in petrol functions as an anti-detonating fuel from which greater efficiency can be obtained than from petrol. Motor cars, omnibuses and motor boats have been successfully run on naphthalene itself as a fuel, although the use of this product necessitated special adaptations in the engine for feeding and carburetting. It is claimed that 1 lb. of naphthalene is equivalent to 0.3 gal. of petrol. As a fuel, however, naphthalene finds its widest application in the manufacture of fire lighters which consist of wood waste impregnated and consolidated by immersion in the molten hydrocarbon.

COAL-TAR DYESTUFFS: *see* DYES, SYNTHETIC.

COALVILLE, a town in north-west Leicestershire, England, 112 m. N.N.W. from London. Pop. of urban district (1931) 21,886. It is served by the L.M.S.R. This is a town of modern growth, a centre of the coal-mining district of north Leicestershire. There are also iron foundries and brick-works. A mile north of Coalville is Whitwick, with remains of a Norman castle, while to the north again are remains of the nunnery of Gracedieu, founded in 1240.

COAST, the edge of the land in contact with the sea. The term (from Lat. *costa*, a rib, side) is sometimes applied to the bank of a lake or wide river, and sometimes to a coastal zone (*cf.* Gold Coast, Coromandel Coast). If the coast-line runs parallel to a mountain range, such as near the Central Andes, it has usually a more regular form than when, as in the *rias* coast of south-west Ireland, it enters between the crustal folds. A recently elevated coast is usually regular, while a recently depressed coast shows the irregularities which were present upon the surface before submergence. Waves and sea-currents are the chief agents in coast sculpture. A coast of homogeneous rock exposed to steady erosion will present a regular outline, but if exposed to differential action it will be most embayed where the action is greatest. A coast consisting of rocks of unequal hardness will be marked, when the wave and current action remains similar throughout, by headlands, "stacks" and "needles" of hard rocks, and bays or gulfs of softer or more loosely aggregated rocks, *e.g.*, the southern shore-lines of the Isle of Wight and of south-western Wales. Subsequently the coast becomes "mature" and its outline undergoes little change as it gains on the land, for the hard rock being now more exposed is worn away faster than the softer rock which lies protected in the bays and re-entrants.

COASTAL MOTOR BOAT: *see* FLEET AUXILIARY VESSELS.

COAST DEFENCE. The term coast defence is sometimes liable to be confused with what is really local defence. It is now accepted that it is not possible to defend the whole length of a coast line of even a comparatively small country like Britain from spasmodic assaults by sea. It is quite possible, however, with an adequate Navy, to give security against invasion or prolonged attack.

Aerial bombardments on a large scale are an entirely separate problem (*see* AIR WARFARE) and their antidote does not come under this heading.

General Principles.—Stated briefly, the only true defence of a country's coast line against attacks from the sea, is a fleet, which, under modern conditions, means a force consisting of battleships, carriers, cruisers, destroyers, submarines and aircraft; and that fleet must be free to move out and give battle to the enemy in the open sea, and not be tied to any particular locality, however important it may seem.

This important principle was not always recognized in the past and there are numerous historical instances of the misuse or lack of understanding of sea power by rulers or even great military commanders. As an example of this defect in the outlook and training of those responsible for the conduct of war, we may note how, in 1588 Queen Elizabeth's Privy Council rejected Drake's plan to mass the available ships into a single great fleet to meet the Spanish Armada before it could approach home waters. To the English Government Parma's army in the Netherlands seemed so serious a menace as to necessitate the retention of an Eastern squadron in the Strait of Dover. They failed to perceive that an army on the mainland would be impotent to invade England unless a safe passage was assured by the presence of a fleet which had already met and defeated the enemy fleet, or had effectively expelled it from the waters to be traversed. As it was, the English naval forces were divided and the western fleet was nearly caught at grave disadvantage in the port of Plymouth. Good tactics, fine seamanship and superior gunnery, redeemed faulty strategy; the Armada was defeated and dispersed; Parma's army never embarked.

BY COURTESY OF THE CONTROLLER OF H.M. STATIONERY OFFICE

SECTION OF GERMAN COAST DEFENCE IN THE WORLD WAR

At a later date we see the fleet itself suffering owing to the prevalence of a faulty doctrine that it was possible to defend the country against attack from the sea, by isolated naval units. About 1870 the British Admiralty was building coast defence ships of very low sea-going and fighting efficiency. These were dotted round the coast of England and at one or two naval bases abroad. They gave an entirely false sense of security to the local inhabitants if not to the country at large. Actually this constituted a typical example of that dispersal of strength which is anathema to the sound strategist. The same false ideas were manifest in the Spanish-American war, when the inhabitants of some of the American sea ports clamoured for guardships.

United States.—The term coast defence, as used in America, is understood to mean systematic protection against hostile attack along coast lines. The great length of the United States coast line makes it both difficult and expensive to secure adequate fortification. In the United States the army and the navy are jointly responsible for coast defence, and operations are carried out under a chief of staff with the Secretary of the Navy at the head of the department. The authorized strength of the Coast Artillery Corps of the Army at the close of 1925 was 14,420 enlisted men and 1,000 officers.

The progress of the work of providing armament for the exposed harbours has been contingent upon congressional appropriations. Great impetus was given the work when public attention was focused upon the grossly inadequate defences existing at the outbreak of the Spanish-American War. Construction was then begun and has since been carried forward on implements, fortifications, guns, mortars, gun-carriages, special ammunition, smokeless powder, high velocity explosives, the development of rapid fire and fire control.

By 1915 all ports of commercial and strategic importance had been fortified with the exception of the entrance to Chesapeake Bay. The fortification of the Panama Canal (*q.v.*) on both sides has been completed and similar work is in progress in all outlying possessions. The present policy of armament of the government calls for the installation for defence of at least one 16-inch gun in or near every harbour.

The modern method of emplacement is to spread the guns over a considerable area, and to have them connected by supply and control lines. Such an arrangement makes destruction by an attacking fleet almost impossible and adds to the difficulty of land operations by an enemy. A large number of American guns are mounted on disappearing carriages where they are completely

concealed from lateral view. The use of aeroplanes in reconnaissance and direction of offensive and defensive action has modified the designs of new coast works and it is believed that in the future many of the guns, large and small, will be mounted on rails and moved to constantly changing positions. In July, 1929, experiments in the United States with a large calibre gun mounted on a truck, hauled by railroads parallel to the coast line, were highly successful, and it is believed plans for the complete mobilization of coast defence may be feasible.

A very striking contrast between the influence of sea power and of shore defences in guarding a coast was afforded during the World War. The German army, having forced its way to the Belgian coast, found that their navy could not afford adequate protection to its right flank against attack from the sea. So there grew up along the miles of coastline between Nieuport Canal, where that flank rested, and the Dutch frontier, the most tremendous system of batteries and other coast defences the world has ever seen, including over three hundred guns, six inch and above.

On the other side of the canal the left flank of the French and Belgian armies also rested on the sea, but the coast behind them was innocent of any sizeable battery which could fire to seaward as far back as Dunkirk, and even this historic fortress relied on a comparatively antiquated armament. Here, however, was the base of a considerable naval force, mostly British, which, throughout the war, effectually safeguarded this section of the coast.

In spite of the array of shore defences on the German side, their coastline and harbours in Belgium were assaulted by heavy bombardments, numerous torpedo attacks and the famous landing and blocking expeditions against Zeebrugge and Ostend (*see* BELGIAN COAST OPERATIONS).

When the problem of Coast Defence is expanded into that of safeguarding a number of widely scattered territories like those composing the British Empire, the whole question of the disposition and allocation of armed forces assumes a much broader aspect. The policy to be adopted must depend largely on international relations and is liable to vary to some extent from time to time according to the distribution of foreign armed forces, particularly those of a naval character. (*See* NAVY.)

Local Defence.—In spite of the fact that to attempt to render inviolate a whole length of coast line will generally be mere waste of effort, the defence of particular localities, such as large commercial ports or naval bases, may often be essential. Such local defence must necessarily vary with geographical and other conditions, but will generally necessitate a combination of sea, land and

air forces. These, in turn, will be effective only if they are either adequate in themselves to meet the largest scale of attack which may be launched against them or if they can hold out until reinforced. Even so, it can seldom if ever be guaranteed that a place will be absolutely secure from any and every form of attack. The best that can be sought for is to make the risks incurred by an enemy so great as to render attack improbable.

All the chief sea Powers have adopted the principle of establishing some form of permanent defences at their more important naval bases. In some cases large ports, mainly commercial in character, also have fixed defences. On the other hand, there is a growing disinclination to expend large sums on fortresses and immobile defences generally and an increasing tendency to rely on more mobile forms of defence, such as submarines, auxiliary surface warships including minelayers, and aircraft.

It cannot be said, however, that the coast defence battery is obsolete. Mobile defences such as the foregoing may be eluded or may be affected by bad weather, when, but for the fixed defences, the locality would be at the enemy's mercy. Broadly speaking, the principle is to provide the minimum permanent defences consistent with the importance of the place to be defended and having regard to its distance from a potential enemy on the one hand, and reinforcements on the other.

It is possible that as air power increases in range, intensity and reliability, it may be found possible to reduce permanent defences still further, but, at present, the aeroplane is not a complete and efficient substitute for the heavy, long-range fortress gun; still less can it replace those naval units which are an essential part of any system of local defence against sea attack. (E. A.)

Technical.—Attacks on defended harbours or anchorages may be from the sea, air or land, and these may be simultaneous. Attack from the land by itself will not be considered here, but history shows that this has proved the most successful method, *e.g.*, Sebastopol, Port Arthur, Tsingtao, and its menace must influence the local defence scheme.

SEA ATTACK

To repel this, naval action alone must be ruled out. A fleet cannot have its freedom for offence crippled by being tied to the mouths of harbours. Similarly air force action alone must be ruled out, partly for the same reason as a fleet and partly because aircraft carrying bombs or torpedoes are not accurate enough for reliance to be placed on them alone to defeat a naval enemy. Therefore the onus of the defence must fall on the land forces although the other two must co-operate. The division of responsibility will be somewhat as follows:—

(i) The army provides all artillery and other defences actually on the land against all forms of attack.

(ii) The navy provides for distant observation and defence on the sea beyond the power of the land forces, and for sea obstructions such as mines or nets.

(iii) The air force, if available, provides distant air observation and co-operates with the other services in attacking enemy sea and aircraft and in assisting the fire of long range guns.

The defences required on land will vary according to the nature of the sea attack.

Defences Against Deliberate Bombardment, Probably from Heavy Ships.—To guard against this, heavy artillery must be mounted. As the ranges of naval guns have lengthened up to as much as 40,000 yards, and ships are well protected, powerful guns are required on shore, say from 12 in. calibre upwards. In the case of ports where, owing to shallow water or for geographical or other reasons it is considered that bombardment need be expected from more lightly armed ships only, lighter guns will suffice.

The guns must be placed so that all the water whence hostile fire is possible may be covered. In some places ships can fire across intervening land. Wherever possible guns should be pushed forward from the object of defence (harbour, dockyard, etc.). The aim should be to keep ships beyond bombarding range of the object or at least to bring effective fire on the ships before the latter come within that range. If the object of defence is close

to the sea, owing to the coastline being unindented, the number of guns will have to be increased.

The guns will be dispersed in batteries but should be able to assist each other with their fire. Generally, two guns will be in each battery, but sometimes they may be placed singly. A gun must have a firm support in the form of a heavy pedestal on a concrete foundation, and the usual mounting is the open or bar-bette type, the only protection for the crew of the gun being a shield which is part of the mounting. Parapets are not required round the gun as the angle of descent of hostile shell would be too steep to make them of service. It is probable that heavy guns will be placed behind features of the ground so that they will be unseen from the sea. In any case they will have to have their fire directed by some instruments separate from them, so that they lose nothing in this way, while there would be the advantage of easier communications up to them and probably greater latitude in choice of sites.

Guns mounted on a railway are not suitable for coast defence as they cannot change their direction of fire sufficiently rapidly. A gun and mounting which can travel by rail and be lowered on to a fixed pivot in a short time, was used by the Germans on the Belgian coast during the World War. Some of this type have been adopted by the United States of America. But the sole advantage in these mountings, that of being able to reinforce threatened points, is more than counterbalanced by not having the guns always on the spot where their crews can be trained with them. This is especially the case where the men come from local sources.

In order to be "knocked out" by a ship a coast gun must receive a direct hit. The chances of this are very slight, since the target presented to the ship is so small. Owing to this and to the very powerful action of a heavy shell, if it does hit, it is better to obtain protection for the battery by dispersing its various parts, giving them only slight material cover than to concentrate them in one place and protect them by sheer mass of material. Concentration would be necessitated on account of the cost of such protection. By this dispersion each part of the battery becomes a separate target for a ship, the guns being separated by some 250 to 500 yards, and the ammunition stored in isolated buildings. These should be above ground, the structure being proof against splinters only. Advantage should be taken however of the shelter given by any features of the ground. Each gun should have several cartridge and shell stores, their internal details being so designed as to allow the ammunition to be handled as quickly as possible. The moving of the shells requires special attention as they are heavy, while the cartridges must be kept at the correct temperature. The stores should not be close to the guns and should have good intervals between themselves, while the means of communication between the battery and the nucleus of the defence, whether it be railway, tramway or road, should pass close beside them. The ammunition should be supplied to the guns on small trucks running on light tramways or on concrete paths.

Accessory parts of a heavy gun battery will be some form of power for working the guns (probably electric), stores for artillery material, etc., and the structures for housing the officers in charge of the guns and their staff, together with the ends of the electrical cables which enable them to receive orders from their superiors and information from the observation posts which give the data for aiming the gun aright.

Range-finding and Observation of Battery Fire.—This is carried out as far as possible by instruments in the above posts, which are established in places whence a view is obtained over the waters commanded by the guns. The principal instrument used is termed the horizontal-base position-finder. This requires a structure at each end of the base to house the angle-finding instruments and their gear. The posts are generally some thousands of yards apart and should be at as great a height as possible in order to obtain the necessary range of view. On low-lying sites use may be made of existing high buildings or it may be necessary to erect towers for the purpose. The posts should be as inconspicuous as possible, though this is difficult to arrange in the case of a tower.

The system of determining the position of an enemy ship is that one post sends its information to the other, called the receiver, where the two observations are combined, either by automatic means or by plotting them graphically. The former method requires more gear and less men than the latter; the difference in speed is slight. The final result, as sent to the battery, gives the angle and bearing of the target ship from the gun. The battery commander should be in a structure beside the receiving post, the position selected being fairly near the battery but well to one side.

Instruments for important guns are often duplicated or alternatives are used such as the self-contained Barr and Stroud rangefinder, which has the necessary base within the instrument itself.

At ranges beyond the view of land instruments or in cases where the ships use extensive smoke clouds for concealment, the assistance of aircraft will have to be obtained to observe the fire of the guns. This will necessitate the provision of a wireless station for the battery commander. It should be realized that aerial observation will not be so accurate as that from fixed instruments.

It is worth noting here that the possibility of jamming the wireless of aircraft has not yet been fully tested. If feasible their value for observation purposes would largely disappear.

A battery to deliver indirect fire as described above is unseen from the sea, but it has to reckon with hostile observers in the air "spotting" the fire of the ships. These observers may sometimes be impeded by the defending aircraft and anti-aircraft artillery but other measures can be taken. It is possible to surround the battery area with a screen of dense smoke. Also the general lay-out of the battery should be made as indefinite as possible, long straight lines should never be used for any part of it. The object of this is to make it difficult for the enemy's airmen to estimate the position of the fall of shell. To further this end, in suitable localities the whole battery area might be planted with trees at intervals. For the same reason portions of a battery, such as tramways, paths, etc., may be concealed under what is known as camouflage (*q.v.*). This would be done on the outbreak of war only, as it is impossible to prevent any potential enemy from gaining information about such a work as a coast battery erected in peace.

Defences Against Attack by Cruisers.—A deliberate bombardment from heavy ships is not an operation to be undertaken lightly by an enemy, owing to the great danger to which these important vessels are exposed and the large expenditure of ammunition involved. A more easily conducted bombardment would be a short one, or what may be called a raid. This may be carried out from heavy ships but is more likely to be the work of cruisers. At defended ports, where it has been decided that only cruiser attack is probable, the guns can be of a lighter nature. Also, since the ranges at which such actions will be fought will be shorter than in the case of heavy ships and may get very short, the guns should be placed where they can see the water themselves (direct-fire batteries). These medium batteries will be situated, as regards the object of defence, on much the same lines as the heavy batteries, but some of their fire should be able to command the water up to the entrance of the harbour and the guns should be at a good height above the water. The battery designs would follow the same general idea as the heavy batteries, modified by the fact that the battery site may be exposed to view from the sea. Everything possible must be done to make the various parts inconspicuous. The guns, probably two to a battery, should be closer together than the heavy guns, firing from mountings of a similar type (with modifications) with no parapet in front. To render them inconspicuous the guns *must* have a background as viewed from the sea which may have to be artificial and paint, judiciously applied to the guns and visible concrete, will assist greatly.

The ammunition stores should be small and dispersed and they must not form objects conspicuous from the sea, every advantage being taken of features of the ground to hide them. Other parts of these batteries would not differ materially from those of the heavy batteries. In both forms of batteries already described ac-

commodation for the officers and men would be restricted to war shelters in the battery area but dispersed irregularly.

Defences Against Attack at Close Quarters.—This attack may be made with the endeavour to penetrate the channel and to torpedo ships lying inside, or to attack dockgates. The craft employed will probably be of a much smaller nature, possibly destroyers or fast motor boats, while submarines might be used, but in most cases they would not be able to enter submerged. The attackers will generally move at high speed.

To meet this form of attack light guns with a rapid rate of fire are required to cover the channel entrance and the water close in front of it. These batteries would be designed so as to give the fullest effect to the guns, the question of protection not being of great importance as the hostile craft will not be able to delay in order to engage them. In these light batteries the ammunition should be kept close to the guns, and shelters for the men on duty should be provided in the immediate vicinity, with sleeping accommodation for the remainder inside the battery. These batteries should not be on very low sites as it is advisable to be able to use the automatic sight, which requires some height. This sight is an adaptation of the vertical-base position-finder in which the act of bringing the target into the field of the sight lays the gun correctly.

Close attacks are most probable at night so that the water in the entrance and near it must be illuminated effectively. This is done by powerful electric searchlights which have a range of some 2,000 yards and upwards, varying with the state of the atmosphere. They may be used as observation lights, illuminated area lights or fighting lights. Observation lights have concentrated beams and are placed at the outer edge of the near defences, being generally in pairs. For ranges beyond that of the lights the artillery can assist by firing star-shell. Illuminated area lights have dispersed beams and are used to light an area of water. Fighting lights are concentrated beams specifically allotted to serve particular guns or batteries.

Defences Against Attempts to Block Narrow Channels by Sinking Ships in Them.—(See BELGIAN COAST OPERATIONS: *Zeebrugge*.) Where it is considered that such attacks are possible, naval assistance is most desirable for the defence, but guns and lights must be provided also to stop the ships before they reach the narrow channel. For some time after 1890 the Brennan torpedo, controlled mechanically from the shore, was used in the British service against such attacks. It is possible that counter-attack by torpedoes, fired from the shore, or carried on manless electrically controlled motor craft, might be used. Such craft, however, might find better employment against ships carrying out deliberate bombardment.

Defences Against Gas Attack.—Such attack might consist of the use of gas clouds or gas shell. If this is deemed possible special measures will be necessary to make gas-proof such places as observation posts, command posts, etc., since the use of ordinary anti-gas appliances worn on the person interferes greatly with the use of instruments.

Defences Against Landing Raids.—Where batteries, electric lights, observation posts, etc., are isolated they will have to be defended by troops. Any works, such as trenches or wire obstacles should be sited irregularly in order not to assist hostile observers.

AIR ATTACK

The scale on which any attack from the air can take place depends upon whether it can start from a land base within reach or whether it can be launched only by sea-borne aircraft. It is more likely that air attack would be directed on the object of defence than on the coast defences themselves, but both are possible. Every use will naturally be made of any defending aircraft, but anti-aircraft guns and searchlights must be provided on the ground to guard both the object of defence and the defence works. The efficiency of these ground defences has greatly improved since the World War.

The chances of a bomb actually hitting such a small target as a coast gun are very slight, but it may be thought advisable in heavy batteries to erect thin splinter-proof walls round the gun

emplacements to guard against the effects of bombs burst in the close vicinity. Also, sometimes a shell-proof, bomb-proof and gas-proof shelter would be provided, with sitting accommodation, for the battery garrison.

DEFENCE ORGANIZATION

A defended port (coast fortress) is under a fortress commander who arranges the co-operation with navy and air force. A large place is divided into sections, each under a commander in charge of all troops in his section. The coast artillery is divided into groups of batteries, called fire-commands, each under an officer. Such a group generally consists of batteries which fire over the same area of water. A fire-command lies wholly in one section.

The tactical control of observation and illuminated area search-lights is exercised by the fire-commander through an electric light director. Fighting lights are controlled by the battery commander whom they serve.

(J. C. M.)

COASTGUARD, a force usually naval in character, maintained in some countries for the suppression of smuggling or affording assistance to vessels in distress or wrecked and for other duties incidental to a seaboard, e.g., signalling, etc.

To cope with the intensive smuggling which followed on the conclusion of the Napoleonic wars a special British preventive service was formed, officered by half-pay naval lieutenants, to work in conjunction with the revenue cutters and riding officers to whom hitherto the duty of the protection of the revenue had been entrusted. Until 1831 the control of this service was vested in the customs, but in that year the service was reorganized and came, for purposes of administration, under the Admiralty, taking the name of Coastguard, but it was not until 1845 that it assumed a naval character. In 1856 the Coastguard Act was passed and the service transferred entirely to the control of the Admiralty. By the provisions of this act the Coastguard were, in time of war, to be used for the defence of the coast and as a reserve for the navy. The protection of the revenue remained, however, the primary function in time of peace.

From the establishment of the Coastguard—both prior to and since its transfer from the board of customs to the Admiralty—certain services connected with wrecks, casualties at sea, and life-saving generally were undertaken gradually by the force.

The main work of the Coastguard in time of peace, therefore, was on behalf of government departments other than the Admiralty, the board of trade and board of customs, the former being the government department responsible by Act of Parliament for the establishment and maintenance of rocket and other life-saving stations on the coast of Great Britain. The personnel were, however, trained regularly in their naval duties, at first by periodical cruises in Coastguard vessels stationed at various ports on the coast and subsequently by embarkation in the fleet during the annual manoeuvres. A certain portion, however, were organized and trained as a signal section for the purpose of manning signal stations around the coast in the event of war. This system prevailed at the outbreak of the World War.

On the conclusion of peace the Coastguard was reorganized, the personnel being composed of naval pensioners in place of active service ratings. The force, however, continued to be officered by officers on the active list and its duties remained substantially the same as in pre-war days.

In 1922 as the result of the recommendations of the Geddes Committee an inter-departmental committee was appointed to enquire what establishment was necessary for carrying out the civil duties discharged by the Coastguard, what arrangements should be made for a divisional responsibility and cost between the departments concerned and what economies consistent with the maintenance of the necessary national services could be effected. The committee reported in effect that the responsibility for revenue protection should be assumed by the board of customs and excise and that the responsibility for the other non-

naval services should be assumed by the board of trade. These recommendations were accepted by the Government and the service was reorganized on the lines recommended as from April 1, 1923.

The Coastguard Act of 1856 was repealed by the Coastguard bill of 1925 whereby it was enacted that H.M. Coastguard shall consist of such numbers of officers and men as the board of trade may, with the consent of the Treasury, from time to time think fit, and shall be raised, maintained, equipped and employed as a coast watching force for the performance of the duties hitherto performed by the Coastguard on behalf of the board.

As a result the Coastguard is now, although very much reduced in numbers, primarily a life-saving service, to which end the organization is directed. The personnel is composed entirely of retired naval officers and pensioners from the royal navy.

In France, although there is no coastguard service in the sense of that maintained by Great Britain and the United States, a number of semaphore stations are established on the coast, manned by long-service men from the navy, called "Guetteurs Sémaphorique." Their duties are primarily concerned with signalling, but the work is also of a life-saving character as a look-out is kept for vessels in danger or distress, while the personnel have charge of and assist to work the rocket life-saving apparatus, should there be one in the vicinity of the station. The service is under the control of the minister of marine, stations being under the command of the maritime prefect of the district.

BIBLIOGRAPHY.—The rise and early history of the Coastguard in Great Britain are told in *Smuggling Days and Smuggling Ways* by the Hon. Henry N. Shaw, R.N. (1892). Information of this nature can be found also in *The King's Customs* by Hatton and Holland. Later history must be traced in the *Queen's (and King's) Regulations and Admiralty Instructions* of successive years. The reports of the Inter-Departmental Conference on the Coastguard held in 1907 (Cmd. 4,091) and of the Inter-Departmental Committee on the civil duties of the Coastguard held in 1922 (Cmd. 1,753) contain much useful information as to the history and the duties of the Coastguard. In the case of the United States full information as to the organization and duties of the Coastguard can be obtained from the annual reports issued by the Treasury on the United States Coastguard; the report for 1921 especially contains much useful information concerning the history and development of the service. (H. J. M. R.)

UNITED STATES

The United States' Coastguard was originally created by an act of Congress approved on Jan. 28, 1915, which combined therein the existing U.S. revenue cutter service and U.S. life-saving service. The act expressly provides that the Coastguard "shall constitute a part of the military forces of the United States, and shall operate under the Treasury department in time of peace, and operate as a part of the navy, subject to the orders of the secretary of the Navy, in time of war or when the President shall so direct."

The Coastguard, through its antecedent, the revenue cutter service, is one of the oldest organizations under the Federal Government. After the Revolutionary War, the continental navy was disbanded. There was no sea force available for the protection of the coasts and the maritime interest of the newly constituted United States until the organization of the revenue cutter service by an act of the first Congress, approved by President Washington on Aug. 4, 1790. The vessels of the revenue cutter service formed the only armed force afloat belonging to the young republic until the navy was organized a few years later. The revenue cutter service was from the first, and still is, charged with the protection of the customs, that is, with preventing smuggling from the sea.

The Coastguard has played a distinguished part in every war in which the United States has been engaged, with the exception only of the war with Tripoli. The records show that of the 22 prizes captured by the United States during the difficulties with France in 1798 and 1799 the Coastguard cutters captured 18, unaided, and assisted in the capture of two others. A Coastguard vessel made the first capture afloat in the War of 1812. The suppression of the piracy which prevailed during the first quarter of the 19th century in the Gulf of Mexico was due chiefly to the Coastguard. The cutters waged a relentless war upon the pirates, pursued them to their every resort and rendezvous, and attacked

BRITISH AND AMERICAN COASTGUARD STATIONS

1. Coastguard lookout hut, Bolt Head, Devon. Lookout hut for vessels in distress, placed on a commanding headland
2. The Lookout, Cromer, Norfolk. This station is equipped with wireless telephone for communication with lightships off the Norfolk coast
3. Old Chicago coastguard station crew holding capsized drill. The United States coastguard maintains stations on the Great Lakes
4. A modern British coastguard station, providing housing accommodation, and equipped with a wagon-mounted rocket life-saving apparatus

and dispersed them wherever found. Vessels of the Coastguard service participated actively in the Seminole Indian War, in the Mexican War and in the Civil War. The cutter "Harriet Lane" was attached to the squadron of naval vessels that was sent to Paraguay in 1858. The Coastguard cutters fought alongside vessels of the navy in the Spanish War. The cutter "Hudson" was actively engaged at the battle of Cárdenas and the cutter "McCulloch" was with Admiral Dewey's fleet at the battle of Manila

TWO COASTGUARD PATROL BOATS PICKETING A FOREIGN "RUM" VESSEL OFF THE NORTH ATLANTIC COAST OF THE UNITED STATES OF AMERICA

bay. When the United States entered the World War, the entire Coastguard, in accordance with law, passed into the naval establishment. Coastguard vessels fought submarines and performed escort and patrol duty in the European war zone, and officers and men served with distinction in practically every phase of naval activity. The sinking of the Coastguard cutter "Tampa," after she had safely escorted her convoy to an English port, by an enemy submarine, Sept. 26, 1918, when every soul on board, 115 in all, was lost, constituted, with the sole exception of the loss of the "Cyclops," the largest individual loss sustained by U.S. naval forces during the war.

In time of peace the Coastguard maintains a constant readiness for war and is prepared to pass into the naval establishment on 24 hours' notice. It is a real and valuable part of the national defence. In addition, it is charged with a large number of important peace-time duties, most of which are essentially humanitarian in their character. Its most important function, in time of peace, is that of saving life and property at sea. Its ships cruise actively along the coasts at all times, and particularly in the most dangerous weather, to render aid to vessels in trouble. In addition to the ships and supplementing their work in rescuing human life, a cordon of 277 Coastguard stations (formerly known as life-saving stations) protects the shores.

The Coastguard clears away derelicts and other floating obstructions to navigation that constitute a very real danger to ships at sea. It maintains the international ice patrol along the trans-Atlantic steamer lanes, a service that was instituted following the sinking of the steamer "Titanic" April 14, 1912. Since the Coastguard took charge of this patrol there has not been a single life lost by collision with icebergs or ice-fields in the North Atlantic. The cutters protect the seal herds and other fisheries in Alaskan waters and visit the remote parts of the Alaskan coast, carrying medical aid and the benefits of law and civilization to the whites and natives in those far northern regions. The Coastguard enforces the regulations governing anchorage of vessels in navigable waters; it aids in the enforcement of the navigation laws governing merchant vessels and motor boats; it suppresses mutinies on merchant vessels; it protects human life and maintains order at regattas and large marine parades. During the great Mississippi flood in the spring of 1927, the Coastguard service sent 674 officers and men and 128 vessels and boats into the inundated regions. It removed 43,853 persons from perilous positions to places of safety and saved 11,313 head of live stock. During the fiscal year ended June 30, 1927, the number of lives saved or persons rescued from peril by the Coastguard was 3,313. The number of derelicts and other obstructions to navigation removed or destroyed was 136. The number of persons on board vessels assisted was 14,496. The value of vessels assisted, including their cargoes, was \$37,801,357. The number of vessels boarded and their papers examined was 68,223.

On June 30, 1927, the Coastguard fleet consisted of 33 cruising cutters, 25 destroyers, 37 harbour cutters and launches, 46 off-shore patrol boats, 198 75-foot patrol boats, 7 other patrol boats and 112 small picket boats. The personnel consisted of 359 commissioned officers, 47 cadets, 22 chief warrant officers, 832 warrant officers and 9,924 enlisted men.

There are 277 Coastguard (live-saving) stations, of which 252 are in an active status. The equipment of Coastguard stations consists of the beach apparatus—line-projecting guns, hawsers, breeches-buoys, etc.—flag and pyrotechnic signals, life-cars and life-boats, surf-boats and other types of boats, all intended to rescue persons in peril at sea. The historic motto of the Coastguard is *Semper Paratus* ("Always Prepared"). (F. C. Br.).

COASTING, usually called tobogganing (*q.v.*) in Europe, the sport of sliding down snow or ice-covered hills or artificial inclines upon hand-sleds, or sledges, provided with runners shod with iron or steel. It is uncertain whether the first American sleds were copied from the Indian toboggans, but no sled without runners was known in the United States before 1870, except to the woodsmen of the Canadian border. American laws have greatly restricted and in most places prohibited the practice, once common, of coasting on the highways, and the sport is mainly confined to open hills and artificial inclines or chutes. Two forms of hand-sled are usual in America, the original "clipper" type, built low, with long, pointed sides, formerly shod with iron but since 1850 with round steel rods for runners; and the light, short "girls' sled," with high skeleton sides, usually flat shod. There is also the "double-runner," or "bob-sled," formed of two clipper sleds joined by a board and steered by ropes, a wheel, or cross-bar, and seating from four to ten persons.

Coasting has become a very popular pastime in the Adirondacks, in upper New York state, where there are numerous artificially constructed chutes in popular resorts.

The chute at Mt. Royal, Montreal, consists of five tracks, side by side, separated by ice. Dufferin Terrace, Quebec, has three tracks. Berlin, N.H., has a famous toboggan chute. The Dartmouth winter carnival, held each winter at Dartmouth college, Hanover, N.H., features tobogganing, coasting, skating, etc.

In Scandinavia several kinds of sled are common, but that of the fishermen, by means of which they transport their catch over the frozen fjords, is the one used in coasting, a sport especially popular in the neighbourhood of Oslo, where there are courses nearly 3m. in length. This sled is from 4 to 6ft. long, with skeleton sides about 7in. high, and generally holds three persons. It is steered by two long sticks trailing behind. On the ice the fisherman propels his sled by means of two short picks. The general Norwegian name for sledge is *skjölker*, the primitive form being a kind of toboggan provided with broad wooden runners resembling the ski (*q.v.*). In northern Sweden and Finland the commonest form of single sleds is the *Sparkstöttinger*, built high at the back, the coaster standing up and steering by means of two handles projecting from the sides.

Coasting in its highest development may be seen in Switzerland, at the fashionable winter resorts of the Engadine, where it is called tobogganing. The first regular races there were organized by John Addington Symonds, who instituted an annual contest for a challenge cup, open to all comers, over the steep post-road from Davos to Klosters, the finest natural coast in Switzerland, the sled used being the primitive native *Schlittli* or *Handschlitten*, a miniature copy of the ancient horse-sledge.

The construction of great artificial runs followed, the most famous being the "Cresta" at St. Moritz, begun in 1884, which is about 1,320yd. in length, its dangerous curves banked up. The famous run has an electrical timing apparatus. The record time for the descent is 53.7sec. made in 1911, an average speed of 47m. per hour. The total drop from start to finish is 514ft., the average gradient 1 in 7.7. On this the annual "Grand National" championship is contested, the winner's time being the shortest aggregate of three heats. In 1885 and the following year the native *Schlittli* remained in use, the rider sitting upright facing the goal, and steering either with the heels or with short picks. In 1887 the first American clipper sled was introduced by L. P.

Child, who easily won the championship for that year on it. The sled used by the contestants is a development of the American type, built of steel and skeleton in form. With it a speed of over 70 m. an hour has been attained. The coaster lies flat upon it and steers with his feet, shod with spiked shoes, to render braking easier, and helped with the gloved hands. This is called the *ventre-à-terre* position. The "double-runner" has also been introduced into Switzerland under the name of "bob-sleigh."

Both bob-sleigh and skeleton-tobogganing are controlled by the International Federation of Bobsleigh and Tobogganing, and both races are included in the winter sports of the Olympic Games. Each nation participating may enter three bobs in each, but only two may compete. Each bob may carry four or five men. At the winter games of the Eighth Olympiad, held in Chamonix in Feb. 1924, Switzerland's second team won and Great Britain's second team were close runners-up, followed by Belgium third, France's second team fourth, Great Britain's first team fifth, and Italy's second team last.

The race was run on four descents of the track, two on each day—the results being determined by the totals of times. The length of the run at Chamonix, starting at the first station of the Téléferique Railway, is 1,433 metres, there are six big curves and in all 18 turns; the track was specially constructed for the Olympic Games and intentionally made difficult. By some experts it is considered dangerous. The French bob of M. le Comte de la Frégoière, which met with disaster, was the only *ventre-à-terre* bob in the race.

In the winter sports of the Ninth Olympic Games held at St. Moritz in Feb. 1928, the United States won the bob-sleigh race, United States second team was second, Germany third, Argentina fourth, Argentina fifth, and Belgium sixth. In the Skeleton toboggan the United States captured the first two places, with Great Britain third.

See T. A. Cook, *Tobogganing at St. Moritz* (1896), and *Ice Sports*, in the Isthmian Library, London (1901); W. Duston White, *The Book of Winter Sports* (1925). (V. M. C.; J. B. P.)

COAST PROTECTION AND LAND RECLAMATION. The boundaries between sea and land are perennially changing. In many sheltered bays and estuaries the sea is receding, while along other portions of the sea coast it is continuously encroaching. The same causes operate to produce both results: the rivers carry down with them detritus and sediment from the higher ground; the sea, aided by wind and tide, is always eroding exposed portions of the seaboard; and even such lesser influences as rain and frost assist in disintegrating cliffs composed of softer strata.

RECLAMATION

The main objects of reclaiming land from the sea are: (a) to increase the area of ground available for cultivation; (b) to gain land of high potential value for some industrial purpose or for municipal expansion. Examples of the first are the fen-land reclamations, the embanking and reclaiming of Sunk Island in the river Humber, and the great Zuider Zee reclamation which was begun in 1920. The reclaiming of nearly 300 ac. of foreshore by the construction of a costly sea embankment at Hodbarnow in Cumberland, for the purpose of mining iron-ore under the foreshore and sea bed, and many instances of reclamation of sites for dock works, such as that begun at Southampton in 1926, are examples of reclamation for industrial purposes. The reclaiming of the foreshore at Back Bay on the west side of the Colaba peninsula at Bombay, begun after the World War, is a notable undertaking connected with city expansion. The high cost of labour and materials compared with the value of agricultural land in recent times has, particularly since the war, rendered works of reclamation, solely with the object of cultivation, in Great Britain at any rate, usually unremunerative.

Reclamation in Estuaries.—Accretion is the increase of land areas brought about by natural forces; e.g., the deposit of silt in estuaries. Land which has been raised by accretion nearly to high-water level can be shut off from the sea by works of a simple nature and the fresh alluvial soil thus obtained is generally

very fertile. Accretion in estuaries is a slow process under ordinary conditions. Directly, however, a fixed channel is secured by longitudinal embankments or training walls, accretion progresses rapidly by the deposit of sediment in the slack-water behind the embankments. Ultimately the time arrives when the water may be altogether excluded by the construction of enclosing embankments; these must be raised above the level of the highest tide, and should have a flat slope on the exposed side, protected, in proportion to exposure and depth of water, with clay, sods, fascines or stone pitching.

In the intermediate stages of the process outlined above much may be done to promote the growth of accretion, or warping as it is termed, and to ensure the fertility of the reclaimed land. The deposit of warp is accelerated by anything which tends to reduce the flow and consequent scour of the ebb-tide over the foreshore: thus considerable advantage will accrue from placing rows of faggots or sods across the lines of flow. The light, fertilizing alluvium only deposits in shallow water at high tide and where there are no tidal currents. The final enclosure, therefore, in the case of land intended for cultivation, should not be effected until this deposit has taken place. A final and rapid deposit can sometimes be effected by making sluices in the banks: the turbid water is admitted near high tide, and retained until the whole of its silt has been deposited, the clear water being allowed to escape slowly towards low tide. Premature enclosure must be guarded against; it is more difficult, the cost greater, the reclaimed land is less fertile and, being lower, less easy to drain.

The practice of reclaiming land in British estuaries is a very ancient one. The Romans effected reclamations in the Fen districts, in Romney Marsh and near Winchelsea; the enclosing of Sunk Island in the Humber was begun in the 17th century, and now produces an annual revenue of something like £10,000; large reclamations in the Dee estuary took place in the 18th century; and, in recent times, works have been carried out in the estuaries of the Ribble, Tees and other rivers. The bulk of the recent work has been with the object of industrial development. For instance, in the Tees estuary large areas of foreshore have been, and are being, reclaimed for factory sites and other industrial purposes by forming banks of iron-slag obtained from the iron-works of the Middlesbrough district. Slag constitutes an excellent material for the construction of reclamation banks in localities where it can be obtained at a low cost near the site of the works. The deposit of alluvial material, during and after embanking, is not an important factor in reclamation for industrial purposes and where the levels of land have to be raised it is usual in such cases to effect this by the artificial deposit of filling material.

Sea-coast Reclamation.—In the reclamation of land adjoining the open coast, sites where accretion is taking place are obviously the most suitable. Marsh lands adjoining the sea, and more or less subject to inundation at high tides, can be permanently reclaimed by embankments; but these, unless there is protection by sand dunes or a shingle beach, are required to be stronger and higher, with a less steeply inclined and better protected slope than is required in estuaries. Waves overtopping the bank will quickly cause a breach, and produce disastrous results; the height of the bank must, therefore, be calculated to meet the case of the severest on-shore gale coinciding with the highest spring tide. Undermining, caused by the recoil of waves on the beach, is liable to occur in exposed sites; this may be prevented by a line of sheet-piling along the outer toe of the bank.

Sea-coast embankments should not generally be constructed farther down the foreshore than half-tide level, as the cost of construction and maintenance would increase out of all proportion to the additional area obtained. It is, as a rule, more economical to reclaim a large area at one time, instead of enclosing it gradually in sections, as the cost varies with the length of embankment; it is, however, more difficult to effect the final closing of a bank, where a large area is thus reclaimed, on account of the greater volume of tidal water flowing in and out of the contracted opening. The final closing of a reclamation embankment is best accomplished by leaving a fairly wide aperture, and by gradually raising a level bank across its entire

length. The embankments in Holland are closed by sinking long fascine mattresses across the opening; these are weighted with clay and stone, and effectually withstand the scour through the gap; the two terminal slopes of the finished sections are similarly protected.

There are many examples of sea-coast reclamation: Romney marsh was enclosed long ago by the Dymchurch wall, where the method of protection adopted in late years more nearly resembles

FIG. 1.—SEA WALL AT DYMCURCH, KENT

the Dutch system than any other work in Great Britain (fig. 1), and a large portion of Holland has been reclaimed from the sea by embankments (fig. 2); the reclamation bank for the Hodbarrow iron-mines illustrates the use of puddled clay to prevent infiltration. The outer portion of this embankment for a length of over 3,000ft. was protected on its sea face by concrete blocks, each weighing 25 tons, deposited "pell-mell" (fig. 3). The sea embankment of the Back Bay reclamation at Bombay (*q.v.*) is an example of modern construction on a rocky foreshore. When completed the length of the wall will be 4 miles.

Breaches in Embankments.—The repair of a breach effected in a completed reclamation embankment is a more difficult task than that of closing the final gap during construction; this is owing to the channel or gully scoured out upon the opening of the breach. When a breach occurs which cannot be closed in a single tide, the formation of an over-deep gully may to some extent be prevented by enlarging the opening. Breaches in embankments have been closed by sinking barges across the gap, by piling and planking up, by lowering sliding panels between frames erected to receive them, and by making an inset wall or bank round the breach.

The gradual drying of reclaimed land lowers the surface some two or three feet; the land therefore becomes more liable to inundation after reclamation than before. Accordingly, it is most important to prevent breaching of the bank by promptly repairing any damage caused by storms; and if a breach should occur, it must be closed at the earliest possible opportunity.

Reclamation by Dredging.—Mention should be made of the method of reclamation by dredging material from the bed of the sea or a river and depositing it on shore or behind an embankment for the purpose of raising the level of existing

FIG. 2.—CHARACTERISTIC CROSS-SECTION OF DUTCH SEA EMBANKMENT OR DIKE

land or converting foreshore or sea-bed into dry land. The method was first used on a large scale in Holland towards the end of the 19th century and has since been extensively employed in many parts of the world (*see DREDGERS AND DREDGING*). The material, whether sand, silt, clay or gravel, is dredged from the sea or river-bed by a bucket dredger or a suction dredger. If the former is employed the dredged material is usually delivered into barges and conveyed to a "pump-ashore" station, where admixture with water takes place, and a pump forces the mixture through a line of pipes on to the land to be reclaimed. If suction

dredgers are used for gaining the material it can be pumped ashore direct through floating pipe lines, if the distance is not too great, or transported by barges from which it is pumped ashore by means of a fixed or floating reclamation pump. In some instances an intermediate pumping station in a long line of delivery pipes has been used to "boost" (*i.e.*, to speed up or relay the flow through the pipes) the mixture of water and dredgings delivered to it from the main dredger.

COAST EROSION AND PROTECTION

There is a difference of opinion about the value of much of the works for coast protection, and some consider that money expended thereon does not give an adequate return. Even in Holland, whose existence depends on the maintenance of its sea walls and defences, authorities are divided on important questions both of principle and practice. Since the close of the 19th century there has been remarkably little development in the means adopted to combat coast erosion; and, generally

FIG. 3.—RECLAMATION BANK FOR THE HODBARROW IRON MINES, 1904

speaking, the methods of construction which still find favour, not only in Great Britain but also abroad, are the same in principle as those which have been used for generations previously. The royal commission on coast erosion, appointed in 1906, whose final report was issued in 1911, collected and placed on record much useful information on the subject of coast erosion, protection and reclamation, not only relating to the United Kingdom but also in reference to foreign countries and Holland and Belgium in particular.

The recommendations of the commission regarding the control of the foreshores of the United Kingdom and the constitution of a central sea defence authority have not yet been given effect to by legislative enactment. The report, however, has served to dispel certain erroneous ideas, particularly as to the extent of the loss of land due to erosion in the United Kingdom, and proves conclusively that the expense of protecting purely agricultural land is out of all proportion to the value of the land thereby saved from destruction.

Causes of Sea Encroachment.—Encroachment of the sea on the coasts is due to erosion of cliffs and shore material. Of the detritus derived from such erosion a portion is carried along shore by the combined action of wind, waves and tides. It remains in a state of more or less constant movement until it is finally deposited to swell an accreting sand or shingle bank, or is driven against some natural or artificial barrier, where it lies and is perhaps buried under subsequent deposits. The travelling shingle and sand or littoral drift is the principal source of the beach materials which form, and make good the wastage from, the foreshores of the coast. But in the course of this lateral travel the particles, large and small, forming the detritus are still further disintegrated. The lighter material is carried off in suspension by the sea and ultimately finds a resting-place on the ocean bed at a level below the influence of wave action or tidal scour.

The remaining portion of the solid materials derived from the destruction of the cliff or shore is more or less immediately transported into deep water, the finer particles being rapidly swept

away by the current until finally deposited on the sea bed, and a certain proportion of the larger material, too heavy to be carried in suspension for any considerable distance, is drawn down the foreshore and the bed of the sea by the under-tow of the waves and ultimately makes its way by gravitation into deep water where it finds a resting place.

Deep Sea Erosion.—The process of erosion and littoral drift is not confined to the foreshore and beach above low-water mark.

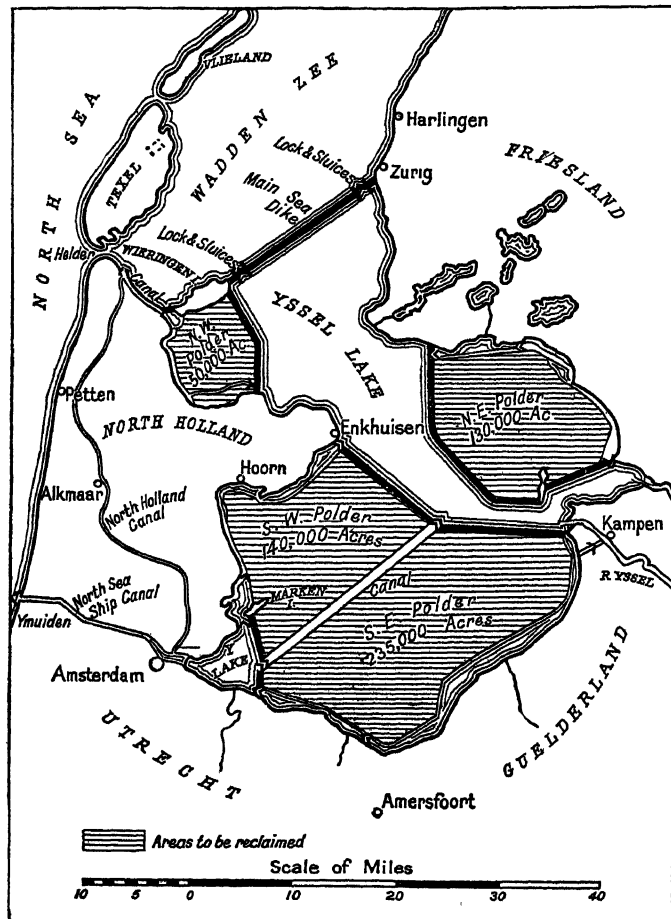

FIG. 4.—SKETCH PLAN FOR THE RECLAMATION OF THE ZUIDER ZEE

Such changes are continuously in progress below low-water where wave action or tidal scour is capable of affecting the sea bottom. These agencies and the gravitating tendency of the particles continue at work until the opposing forces reach a condition of equilibrium. Under certain conditions material lying on the sea bed below low water and in shallow depths is driven back on to the foreshore, but this is merely a temporary phase in the progress of littoral drift. With change of wind or tide the conditions may be reversed.

Conditions Affecting Littoral Drift.—The direction of the prevailing littoral drift is in general governed by the direction of the flood-tide, the prevailing winds and the shape of the coast. Opinions differ as to the relative effect of tide and wind, and although the direction of drift is at times varied by the wind direction, and the consequent wind waves, most competent authorities agree that, in the case of Britain at any rate, the prevailing drift coincides with the set of the flood-tide. In fact, on the British coasts the direction of the flood-tide does generally coincide with the direction of the prevailing winds. On the east coast the drift is from north to south and on the south coast from west to east; in both cases in the direction of the flood-tide and prevailing wind.

Where a coast-line is broken up by deep bays and indentations no continuous drift can take place, each bay retaining its own characteristic material which is prevented from leaving it by the projecting headlands extending to low water or beyond and

forming natural groynes. Numerous examples of these conditions are found on the south coast of Devon and Dorset. The direction of the flood-tide is also in many cases altered locally by the configuration of a bay; e.g., the deflection of the tide along the shores of the bay in a direction opposite to that of the normal coastal current. In cases where a coast-line is broken up by estuaries or rivers the results are variable, depending upon the continual struggle which takes place between the opposing forces affecting littoral drift and the tidal inflow and outflow of the river, the latter sometimes aided to a material extent by the addition of large volumes of fresh water.

During strong winds in a direction contrary to the set of the tide the normal travel of drift may be nullified or even reversed. The accumulation of material on a foreshore is generally brought about by tidal and wave action in calm weather, and a beach which has been depleted during a long spell of heavy weather usually makes up again, at any rate to a partial extent, on the occurrence of calm sea and the cessation of wind. This replenishing is due to the return of a portion of the material previously drawn down into shallow water below low-water mark. Generally speaking, on-shore gales result in the drawing down of the beach material and its gravitation towards the deep sea. Off-shore winds, on the other hand, frequently lead to the accumulation of material on a foreshore.

In order to increase the extent of a foreshore or to maintain it even in its existing condition, the natural and incessant losses must be made good by accretion or the trapping of material derived from other parts of the coast. This may be done in favourable circumstances by the construction of groynes or other works similar in effect, but the accretion through their agency is in every case accomplished to the detriment of neighbouring foreshores. Thus the large groynes at Brighton trap for the time being the greater part of the shingle travelling from west to east, and very little passes on to the foreshore to the east of Brighton, which has consequently become denuded.

Effect of Artificial Projections on Adjoining Coast.—The construction of solid piers or other similar obstructions at an angle with the general shore line and projecting into the sea is, when occurring on a coast-line subjected to erosion, almost inevitably followed by serious depletion of the foreshore to leeward. The solid projection, which in many cases is carried sufficiently far in a seaward direction to reach comparatively deep water, effectively hinders the passage of littoral drift from its windward to its leeward side. (The terms "windward" and "leeward" are used in the sense understood by engineers engaged in coast protection work; viz., "windward"—the direction whence the prevailing littoral drift proceeds; and "leeward"—the direction towards which such drift takes place.) Thus the

FIG. 5.—CHARACTERISTIC CROSS-SECTION OF THE MAIN SEA DIKE IN THE RECLAMATION OF THE ZUIDER ZEE

erosion of the lee shore is accelerated by the loss of the travelling material which under natural conditions makes good to a partial extent the ravages of the sea. Instances of such stoppage are numerous on the English coast. The Folkestone harbour pier has arrested the travel of the beach from the westward, and led to the accumulation of a large bank on that side and the denudation of the foreshore to the east of the harbour and towards Dover. The construction of the harbour works at Dover has stopped the eastward drift at that point and accelerated the destruction of the cliffs in St. Margaret's Bay. At

Lowestoft the construction and subsequent extensions of the harbour pier and other works which project at right angles to the coast-line at the sea outlet of Oulton Broad have resulted in the accumulation of a bank of shingle to the northward and serious encroachments on the town frontage to the south of the harbour.

Sea Walls.—The conditions affecting the design of a sea wall differ so materially that every case must be considered on its merits and provided for accordingly. Sea walls may be divided roughly into two classes, sloping and upright, each class having its advocates among engineers. Generally speaking, walls having a sloping face are used in Holland and Belgium, whilst a vertical or nearly vertical face is more common in Great Britain. The immediate effect of the construction of a wall is detrimental to the beach in front of it, although affording protection to the cliff or banks behind. Thus the construction of a sea wall on a sand or shingle foreshore is in itself calculated to bring about the denudation of the beach and the wall may become before long the agent of its own destruction. Whilst the wall will prevent erosion by the sea of the cliffs in rear of it, the beach in front of the wall must be protected and conserved by the construction of groynes. Many walls have failed through the displacement of the filling behind them by wave action; the provision of a substantial and wave resisting surface or paving behind the wall is, therefore, of great importance, and has been too often neglected. Suitable provision for the drainage of the cliffs, where they exist at the back of sea walls, is also a matter of high importance which also has often been neglected with disastrous results. Much can undoubtedly be done by draining, sloping and planting, to preserve and protect cliff faces, and these works ought to proceed simultaneously with the carrying out of sea-defence undertakings, when the cost of the latter is justified, to protect the foot of the cliff.

Sea walls subjected to abrasion by shingle are, if faced with concrete, very liable to progressive and serious damage. In such positions a concrete wall is frequently protected by a facing, at any rate over that portion subjected to abrasion, of hard stone or flints. For this reason also reinforced concrete is unsuitable for use in the face work of walls on a shingle beach, as the wearing away of the concrete soon results in exposure and deterioration of the steel reinforcement.

Upright sea walls, with some batter on the face, have been constructed along the frontage of many sea-side towns, with the double purpose of making a promenade or road, and of affording protection. A very sloping and also a curved batter reduces the effective stroke of the wave by facilitating its rising up the face of the wall, but the force of the recoil is correspondingly augmented. A vertical face offers more direct opposition to the wave, minimizes the tendency to rise and, consequently, the recoil; while a stepped face tends to break up the wave both on

FIG. 6.—SEA WALL AT HOVE, SUSSEX

ascending and recoil, but there is a corresponding liability to displacement of the face blocks of the wall. The sea walls shown in figs. 6, 7 and 8 exhibit straight, stepped and curved forms of batter. The building of the Scarborough wall (1887) was followed by erosion of the shale bed on which it was founded, and further protective works, including aprons and groynes, had to be added subsequently. A sea wall at Bridlington, constructed in 1888, and, like the walls at Hove and Scarborough, protected by groynes, is shown in fig. 9. At Blackpool walls of the Dutch type but with somewhat steeper aprons have been built on an extensive front (fig. 10).

Groynes.—However effective they may be in collecting travelling material, groynes will not in all cases prevent the waves

reaching the top of a cliff or bank and eroding it to a greater or less extent. A combination of the two forms of protection—groynes and wall—is frequently desirable, but groynes alone have on many low-lying foreshores, particularly where there are no cliffs, proved successful and efficient without the construction

FIG. 7.—SEA WALL AT MARGATE, KENT

of sea walls or protected banks, as for instance on the four m. of shore between Worthing and Shoreham. In some cases protection of the crest of a beach above high water has been secured with success by the construction of a timber barrier or wave screen, formed of piles spaced apart and driven parallel to the line of shore. Groynes may be divided into two main classes: (1) high and substantially built structures of timber or other material; (2) low groynes of inexpensive and light construction usually placed at short intervals apart. In general low, light groynes are suitable on flat, sandy foreshores which are not exposed to sudden and extensive changes of level. In any case it is undesirable to build up the planking of a groyne to a considerable height above the foreshore level existing at the time of construction, and it is preferable to raise the groyne by the addition of planking to keep pace with the accretion of beach material. The use of reinforced concrete for the construction of groynes has frequently been advocated, but is unsuitable on shingle beaches on account of the rapid abrasion of the thin concrete covering of the steel reinforcement.

Groynes although, in Britain, usually constructed of timber are sometimes built of concrete or masonry; examples are the high groynes at Brighton and Hastings (fig. 11), which are faced with flints to protect the concrete from abrasion by shingle. A typical high timber groyne at Eastbourne is shown in fig. 12 and a low groyne of lighter construction in fig. 13.

Groynes, speaking generally, to be of maximum efficiency should be at distances apart about equal to, or little more than, their length. They should extend continuously from the shore or work to be protected to the vicinity of low water of spring tides. There is much diversity of opinion and practice with regard

FIG. 8.—SEA WALL (NORTH CLIFF) AT SCARBOROUGH, YORKSHIRE

to the direction in which groynes should point. Some authorities advocate their direction at right angles to the shore line, others pointing slightly to windward and some prefer a leeward direction. No general rule can be laid down and a plan suitable for one locality may prove a failure in another. The opinion of the majority of authorities, however, appears to favour a direction pointing slightly to windward.

Relative Extent of Loss and Gain of Land.—The evidence as regards the total superficial area gained and lost in recent years on the coasts and in the tidal rivers of Great Britain shows

that far larger areas have been gained by accretion and artificial reclamation, taken together, than have been lost by erosion. Evidence laid before the royal commission by the Ordnance Survey Department in 1907 showed that within a period, on the average, of about 35 years, about 6,640ac. had been lost to the United Kingdom, while 48,000ac. had been gained. Most of the gain has been in tidal estuaries, while the loss has been chiefly

FIG. 9.—SEA WALL AT BRIDLINGTON, YORKSHIRE

on the open coast. Moreover, the gain has been due in the main to the deposition of sediment brought down by rivers and to artificial reclamation. It is, however, probable that the land lost has been more than compensated for by land naturally accreted. The report of the royal commission contains the following statement:—

"The erosion . . . would have been far more serious if extensive works of defence had not been constructed by local authorities, railway companies and others, at a great cost, though, on the other hand, such works in many places have been responsible for erosion of the neighbouring coasts by interfering with the normal travel of the beach material. On the whole we think, however, that while some localities have suffered seriously from the encroachment of the sea, from a national point of view the extent of erosion need not be considered alarming."

Removal of Shingle.—Beach material is too often limited in quantity and the question arises whether its removal for commercial purposes should be allowed. The results of natural erosion and denudation are, in many instances, aggravated by

FIG. 10.—CHARACTERISTIC CROSS-SECTION OF SEA WALLS AT BLACK-POOL, LANCASHIRE

this practice. The powers possessed by the Board of Trade provide for the issue of prohibitory orders and, in certain circumstances, where the removal of beach or sand can be shown to be injurious, such orders have been frequently made.

Cost of Coast Protection.—The cost of construction of groynes varies very considerably with the design and local conditions. Before the World War light low groynes might be constructed at a cost of from 10s. to £1 per foot lineal, and groynes of more substantial construction from £1 to £3 per lineal foot, while some of the large concrete and masonry groynes, of the

type frequently constructed at Brighton and Hastings, cost as much as £7 or £8 per lineal foot. The initial capital cost of protection per mile of shore was seldom less than £4,000, even when no sea wall was constructed. Under present conditions these figures should be nearly doubled. The annual charge for repairs, interest on capital, and replacement may be put at not less than 10% of the original capital cost.

The cost of protecting purely agricultural land which is subject to erosion must of necessity, under the conditions which usually prevail, be considerably in excess of the value of such land. Protection under such conditions is only justified when agricultural land is in the vicinity of towns, and erosion, if not stopped, is likely to lead to those towns being outflanked by the sea and in situations where the works have as their object the preservation from inundation of areas of low-lying land of considerable extent. It is not desirable, even if it were practicable, to prevent erosion of all parts of the coast, as the waste of the cliffs provides the greater part of the beach material which acts as the most valuable agent of protection.

The expenditure incurred in the construction of sea defences by many of the coastal towns of Britain in recent years has been very considerable and in some cases has imposed a heavy burden on the inhabitants. As an instance the case of Sidmouth, a seaside town on the south coast of Devon, having a population of about 6,000, may be referred to. As a result of exceptional gales the sea defences of the town over a frontage of under half a mile were seriously damaged and undermined between the years 1917 and 1925 and the construction of new sea walls and groynes, completed in 1926, entailed an expenditure of over £100,000.

Sand Dunes and Alluvial Flats.—The preservation of sand dunes is most important along certain parts of the coast where they afford protection to low-lying areas behind them, and they should in these cases be maintained and fostered by the encouragement of the growth upon them of marrum and other grasses, which help to bind the sand together. Where drifting of blown sand occurs much may be done to check it by the fostering of

FIG. 11.—CROSS-SECTION OF CONCRETE GROYNES AT HASTINGS, SUSSEX

FIG. 12.—CROSS-SECTION OF CHARACTERISTIC HIGH TIMBER GROYNES AT EASTBOURNE, SUSSEX

such grasses. The process of natural accretion on alluvial flats has been hastened in many cases by the planting of suitable vegetation such as rice grass (*spartina*), and in this way land may in time be reclaimed by entirely natural means.

CONDITIONS IN HOLLAND AND BELGIUM

A large part of Holland and some portions of Belgium are below the normal sea level and are protected from inundation by artificial embankments (dikes) or by narrow belts of sand dunes. The foreshore works on the coast of Holland and Belgium, although of great interest and attended with considerable success, do not afford examples to be followed as affecting the sea defences of Great Britain and other countries exhibiting physical characteristics similar to those of the latter. The protection works

in such cases as Blankenberghe, Heyst, Scheveningen, Kallantsoog and Petten are of great magnitude and the engineers responsible for these works, particularly in Holland, have at their command the accumulated experience of centuries of sea-defence work. The local conditions with which these works have to conform—viz., low flat foreshores consisting entirely of sand—are wholly different to those generally associated with sea-defence works in

England. The large expenditure involved is justified by the necessity of securing the safety, not only of the sea-board, but of large tracts of the countries themselves. Investigations in Holland are said to indicate a continuous subsidence of the land of that country relative to the sea level, amounting to about 15cm. per century.

The North sea foreshores of Holland and Belgium consist for the most part of fine sand; similar deposits border the lower portions of the numerous river estuaries which penetrate far inland, but in the higher parts of these the foreshores are generally composed of fine sand covered with clay or mud. The foreshores of the North sea between high and low water have an average gradient of about 1 in 45 and the shores above high water normally slope at about 1 in 25. Submerged sandbanks more or less parallel to the shore are a characteristic feature of the North sea and estuary coast-lines of Holland and Belgium. These, where they exist, afford considerable protection to the sandy shores during on-shore gales. In calm weather and with off-shore winds sand accumulates on the foreshores.

SEA DEFENCE WORKS

The most important forms of sea defence works in common use in Holland are: (a) groynes, (b) sea walls or "dikes" and (c) fascine mattresses with stone ballasting for the protection of submerged banks.

Groynes.—Groynes are usually constructed at right angles to the shore line and are maintained as a rule at a small height above the average foreshore level. On those portions of the North sea coast which are most exposed, groynes are placed about 250

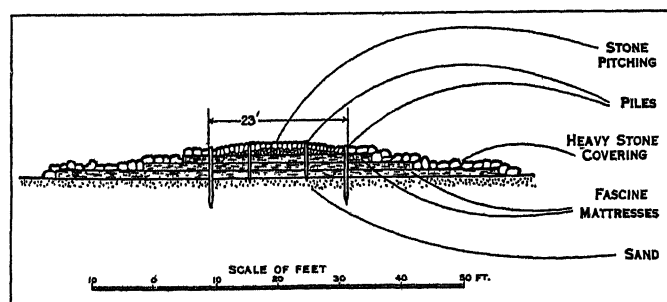

FIG. 14.—CHARACTERISTIC CROSS-SECTION OF MATTRESS GROYNES ON THE COAST OF NORTH HOLLAND

metres apart and are extended out beyond the low-water line. Many of the groynes on the Dutch coast are constructed of layers of fascine mattresses covered by heavy stone, having their crests almost flat or turtle-backed with side slopes of 1 in 2, or flatter. The fascine or brushwood mattresses are held together and pinned down by rows of piles. Wide brushwood aprons, with heavy stone covering forming flat slopes, are constructed on either side of the groyne in order to protect the flanks against scour (fig. 14). The groynes are carried up above the line of high water to meet the base of the sand dunes or the protecting dikes. These groynes, inclusive of the side aprons, are often of considerable width, sometimes as much as 30 metres at their deepest and widest parts. The cost of groynes recently built in Holland has varied from £4,000 to £11,000 each.

On the coast of Belgium at Blankenberghe and in its vicinity the shore is groyned on an extensive scale. The groynes on the average are about 820ft. long and 680ft. apart; they resemble the typical Dutch groyne in form and are constructed with a foundation of mattress work or concrete, faced with brickwork or stone pitching (figs. 15 and 16).

Dikes.—On much of the North sea coast-line of Holland and Belgium, where the beach is protected from erosion by groynes,

FIG. 15.—CHARACTERISTIC CROSS-SECTIONS OF GROYNES AT OSTEND AND BLANKENBERGHE, BELGIUM

the sand dunes or the coastal embankments (dikes) are frequently protected by a flat slope of brickwork, or basalt or other stone pitching, or concrete slabs laid on beds of clay, rubble and mattress work (fig. 2). In situations, such as Scheveningen and Ostend, where a promenade has been formed on the sea embankment, a curved faced wall is sometimes substituted for the upper part of the normal slope of the paving thus reducing the width of the protecting works (figs. 17 and 18); but over large stretches of coast, particularly in Holland, a simple flat paved slope is the common practice.

Protection of Submerged Banks.—The underwater banks of some of the estuary channels and sea inlets on the Dutch coast often stand at a steep slope with deep water alongside. Under these conditions there is serious liability to erosion and it is usual to protect the banks both above and below water by artificial means. For many years fascine mattresses have been used for this purpose. These are made up on a convenient sandy foreshore, covered at high tide, and, when completed, are towed to the place where they are to be used and sunk on the sea bottom by ballasting with stone. They consist of two layers or grids of brushwood each

FIG. 16.—PLAN OF GROYNES ON NORTH SEA COAST AT BLANKENBERGHE, BELGIUM

built up of crossed rows of parallel brushwood ropes, 0.4 metre circumference, and spaced 0.9 metre apart centre to centre, bound tightly together with a filling of brushwood in three layers between them. On the top of the upper brushwood grid, openwork partitions are formed for the reception of stone ballast. Formerly, clay mixed with a little stone was used for ballasting, but in modern practice stone alone is employed, the mattresses being weighted to the extent of 1,000kg. per sq. metre. The cost of continuous protection of the steep banks of the estuary channels, where the depth of water alongside is sometimes as much as 100ft., is very

considerable, amounting in some cases to as much as £100 per metre run of bank. In some localities the cost has been reduced by the construction of intermittent mattress work, leaving short unprotected stretches of bank between projecting spurs which serve to deflect the main current away from the unprotected embayments. In cases where the sea bed of the deep channels consists of clay, erosion is not so uniform as that of sandy bottoms and the side slope is sometimes very steep, exceeding 1 to 1 in certain cases. In such situations rubble stone ballasting or surfacing of the bank is preferred to the employment of mattresses. (In Great Britain stone protection of this nature is known as "revetting.") The protection of the shore lying between the steep submerged and partially submerged banks of the channels and the base of the dike or wall which forms the immediate protection of the land behind, is usually effected by means of groynes. These shores, which are sometimes of considerable width above the level of normal high water, have in most cases flat gradients.

THE RECLAIMING OF THE ZUIDER ZEE

The partial reclamation of the Zuider Zee, undertaken by the Dutch Government in 1918, is the greatest work of its kind ever attempted. The earliest plans for regaining the submerged lands of the Zuider Zee date from the 17th century, but it was not till the middle of the 19th century that serious proposals began to be considered. Among these plans were those of van Diggelen, 1849, Leemans, 1877, and the various schemes of the engineer C. Lely, subsequently Minister of Public Works, which appeared between 1887 and 1891; the last of which is substantially that on which work was actually commenced in 1920. The finally approved scheme as shown in the plan fig. 4 includes: (1) a sea dike about 1½ m. long between the mainland of north Holland and the island of Wieringen, completed in 1926; (2) a drainage and navigation canal for small vessels, also finished in 1926, extending from the western end of the Wieringen dike near van Ewijksluis along the coast of North Holland to Helder. This canal will maintain the access from the Texel channel to the old North Holland canal at de Kooi by a lock at that place, and connect with canals to be formed along the eastern coastline of North Holland up to Amsterdam; (3) the main sea dike, about 18½ m. long, from the eastern end of the island of Wieringen to the Frisian coast near Zurig (figs. 4, 5 and Plate). Two sets of

FIG. 17.—CROSS-SECTION OF SEA EMBANKMENT AT OSTEND, BELGIUM

sluices will be provided, one set near each end of the dike, the total width of the sluice openings being about 1,000 ft. Navigation locks for vessels up to about 2,000 tons in capacity are also to be built near the ends of the dike. This part of the work was commenced in 1926 and is expected to be completed in 1934. A large part of the section of the sea dikes is formed of boulder clay dredged from the Zuider Zee, brought to the depositing sites in barges and unloaded by grab dredgers. The sand filling of the dikes is pumped; (4) the reclamation of four areas (polders), by the construction of secondary dikes inside the sea dikes, aggregating about 553,000 ac. thus increasing the total land area of Holland by about 7% and the arable land alone by 10%; (5) The formation, inside the main sea dike, of an inland fresh-

water lake of about 247,000 ac. called the Yssel lake, to provide for the disposal of the flood waters of the river of that name, and a canal, about ¾ m. wide, connecting this lake with a smaller one (Y lake) to the east of Amsterdam. This canal will separate the south-west polder from the south-east polder and will have a regulating lock and sluices at its entrance from Lake Yssel.

The draining of the reclaimed land will be accompanied by a shrinkage, the amount of which, it is expected, will vary between

FIG. 18.—CROSS-SECTION OF SEA WALL AT SCHEVENINGEN, HOLLAND

one and three feet. All the polders will be at levels considerably below sea level, and the lowest drainage channels will be as much as 22 ft. below the Yssel lake level. Pumps will be installed at points on the borders of the polders to provide for the drainage of the land. They will lift land water up to the level of the lake and discharge it over the secondary dikes.

The reclaiming of the north-west polder (Wieringen) was commenced in 1927; and it is proposed to begin the work on the three remaining polders as soon as the main sea dike is completed, probably in 1934. The north-west polder will be finished about 1932, but cultivation will not be possible till three or four years later. It is calculated that the lands will not have become so free from salt as to reach their full capital value until the 14th or 15th year from this commencement of the reclamation of a polder.

In addition to the main features already mentioned, the scheme includes many important subsidiary works such as minor canals, locks and sluices, drainage arrangements, roads and bridges. The latest estimate of the total cost of the work amounts to £45,000,000, inclusive of interest during construction and development, but not including the compensation of the Zuider Zee fisheries and some other items. It is estimated that, when the last of the lands to be reclaimed has acquired its full capital value about the year 1959, the undertaking will have shown a profit to the State of at least £8,000,000. The average selling value of the land at full maturity is estimated at about £90 per acre.

BIBLIOGRAPHY.—The *Reports and Evidence: Royal Commission on Coast Erosion and Reclamation of Tidal Lands*, particularly the final report, Cd. 5,708 (1911), should be consulted both for Coast Erosion and Reclamation. Vol. i, part 2, i. Cd. 3,684 (1907), contains a useful bibliography by W. Whitaker, F.R.S., up to 1906. The Bibliographic lists issued by the International Association of Navigation Congresses, Brussels (since 1908) are very complete. Another good bibliography of works in English was issued by the Engineer School Library, Washington, D.C., in 1926. The best comprehensive account of coast protection for general readers is W. H. Wheeler's *The Sea Coast* (1902). See also A. E. Carey and F. W. Oliver, *Tidal Lands* (1918); and D. W. Johnson, *Shore Processes and Shore Line Development* (1919). The latter and the periodical reports of The Board of Commerce and Navigation, New Jersey, on *Erosion and Protection* should be consulted for conditions in the United States. For Holland see papers by A. T. de Groot in *De Ingenieur*, No. 35 (1911), and R. P. J. Tutein in *Die Gids*, Nos. 3 and 5 (1913). Samuel Smile's *Lives of the Engineers* contains good accounts of early reclamation works. See also E. M. Ward, *English Coastal Evolution* (1922); W. H. Wheeler, *History of*

COATBRIDGE, municipal burgh, having the privileges of a royal burgh, Lanarkshire, Scotland. Pop. (1931), 43,056. It is situated on the Monkland canal, 8 m. E. of Glasgow, with stations on the L.M.S.R. and L.N.E.R. Until about 1825 it was only a village, but since then coal and iron mining have been developed, and it is now a centre of the iron trade of Scotland. Its prosperity was largely due to the ironmaster James Baird (*q.v.*). The industries of Coatbridge produce malleable iron and steel boilers, tubes, wire, tinplates and railway wagons, tiles, fire-bricks and fire-clay goods. The town, which became a municipal burgh in 1885, forms with Airdrie one of the parliamentary divisions of Lanarkshire. About 4 m. west by south lies the coalmining town of Baillieston.

COATES, ALBERT (1882–), English conductor and composer, was born at St. Petersburg (Leningrad), April 23, 1882, and was sent home to England to be educated at Buckhurst Hill school, Essex, and then at Liverpool university. Later he studied at Leipzig Conservatoire and had his first experience of conducting as *répétiteur* at the opera there under Nikisch. He was then conductor at Elberfeld (1906), and joint conductor with Schuch at Dresden. From Germany he went to Russia as conductor of the Imperial Opera at St. Petersburg, a post which he held for five years. He appeared in England from time to time, but it was not until 1919 that he made London his permanent headquarters and established himself in the favour of the British public as one of the leading English conductors. He has also conducted in Paris, in New York and in other American cities, and for two years (1923–25) was director of the Philharmonic orchestra at Rochester, U.S.A.

COATES, JOSEPH GORDON (1878–), New Zealand statesman, was born at Matakoho, the son of a farmer. He was elected M.P. for Kaipara in 1911, and impressed his leader, Mr. W. F. Massey, with his solid ability. From 1917 to 1919 he served in France with the New Zealand forces, in which he attained the rank of major and gained the Military Cross. Shortly after his return home, he joined the Cabinet, and, as head of the Public Works, Railways and other departments proved himself a capable administrator. When Mr. Massey died in 1925 he was his obvious successor. As prime minister the chief aim of his domestic policy was the consolidation of the primary industries of New Zealand, thus paving the way for a development of secondary industries. His ministry was occupied with the settlement of difficulties in the Samoan mandated territory, and with the revision of the tariff and the concomitant extension of imperial preference.

COATESVILLE, a city of Chester county, Pennsylvania, U.S.A., on the west branch of Brandywine creek, 38m. W. of Philadelphia. The Lincoln Highway is its main street, and it is served by the Pennsylvania and the Reading railways. The population in 1920 was 14,515, and in 1930 was 14,582 by the Federal census. It has two important steel plants, in addition to numerous other manufacturing industries. The total factory output is valued at about \$30,000,000 a year. Coatesville was founded about 1800, and was named after Jesse Coates, one of the early settlers. It was chartered as a city in 1915.

COATI, or COATI-MUNDI, the name of the members of the South and Central American genus *Nasua*, of the mammalian family *Procyonidae*. They are recognized by their long body and tail, and elongated, upturned snout. The tail is often prominently banded. Coatis are gregarious and arboreal in habit, and feed on birds, eggs, lizards, and insects. They are often tamed as pets. (*See CARNIVORA.*)

COATS, J. & P., Limited. The founder of this business, James Coats (1774–1857), was the son of a weaver in Paisley, Scotland, who in 1826 built a small factory—which still forms a diminutive part of the present Ferguslie works—for the manufacture of sewing cotton. James Coats retired in 1830 and gave up his thread business to his sons James and Peter, the firm of J. & P. Coats being then formally constituted, and a third son, Thomas, joined soon after.

J. & P. Coats and Clark & Company, also located in Paisley, the two largest British manufacturers of sewing cotton, were keen

rivals, but both prospered. In 1889, along with Brook, a Yorkshire firm, they formed a company to sell their goods under a joint arrangement whereby economies were effected by concentrating in one dépôt in each important centre and employing one traveller to visit customers in each district, instead of the three firms as hitherto maintaining separate equipment. For seven years this system continued, the collections being paid over in proper proportion to the respective firms. The next stage was an amalgamation of the three, together with a manufacturer in Lancashire named Chadwick, so that since 1896 the parent company of J. & P. Coats Limited—it had become "Limited" in 1890—embraced all four concerns.

Upwards of 80% of the product of Messrs. Coats's mills in Great Britain was in 1927 sent overseas, the company having agents and connections in every country in the world. In addition, it had interests in mills in the United States and elsewhere.

The capital of the company was £20,250,000. (M. N.E.)

COB, something round, stout, tufted or like a head (possibly from Ger. *Kopf*, head). The principal uses of "cob" are for a stocky, strongly-built horse, from 13' to 14 hands high, a small round loaf, a round lump of coal, in which sense "cobble" is also used, the central part of the fruiting spike of the maize plant, and a large nut of the hazel type, commonly known as the cob-nut. The fruiting spike of Indian corn is called corn on the cob.

COBALT, a mining town on Cobalt lake, Timiskaming, northern Ontario, Canada, 330m. N. of Toronto, on the Temiskaming and Northern Ontario railways. Unknown till 1903, it is now the centre of one of the richest silver districts in the world. The region also produces cobalt, arsenic and nickel in large quantities. Pop. (1931) 3,885.

COBALT, a metallic chemical element closely allied to iron and nickel (symbol Co, atomic number 27, atomic weight 58.97). Though the atomic weight of cobalt is slightly greater than that of nickel, the properties of cobalt indicate it should precede nickel in the periodic classification, a conclusion confirmed by the fact that 28 is the atomic number of nickel (*q.v.*, also ATOMIC NUMBER). The term cobalt is met with in the writings of the alchemists, and was used to designate in general substances which resembled metallic ores but yielded no metal on smelting. The term was particularly applied to two ores, cobaltite and smaltite, both of which contain cobalt combined with arsenic. These ores closely resemble metals and were termed "kobold" (goblin, compare Greek, *κόβαλος*), by the Saxony miners, because they gave off poisonous arsenical fumes on smelting and yielded no silver, despite their silver-white appearance.

Occurrence.—The metal was first prepared in an impure condition by G. Brandt in 1733, who found it to be magnetic and very infusible. It is found free in nature, though only in small quantities, chiefly in meteorites and its presence has been detected in the sun and many stars. In combination cobalt is fairly widely distributed, but it occurs seldom except in association with other metals, such as iron, nickel, copper, manganese, antimony and bismuth. It is remarkable that practically all the ores of cobalt are arsenical and consist of arsenides, arseno-sulphides or arsenates. But it has been found as monoxide, CoO, along with manganese in wad, as sulphide, CoS, in jaipurite, and as hydrated sulphate or vitriol, CoSO₄·7H₂O, in bieberite. The crimson hydrated arsenate, erythrite, Co₃(AsO₄)₂·8H₂O, is probably a hydrolytic oxidation product of the arsenide, as the sulphate is of the sulphide. The chief source of the ores smelted in Great Britain is Queensland, Australia, where smaltite, CoAs₂, occurs associated with erythrite. The cobalt speiss, resulting from the roasting of the ore to form oxide and arsenate, contains from 40 to 60% of cobalt with only very small amounts of nickel, iron and traces of other metals. Smaltite is also found at Cobalt, Ontario, Canada, but contains only about 10 to 20% of cobalt in the roasted speiss, together with larger amounts of nickel, and varying amounts of copper, silver and the platinum metals, chiefly palladium, platinum and rhodium. Considerable quantities of cobaltiferous residues result from the production of nickel and copper in Ontario, and are either worked up for cobalt or smelted without purification for alloy purposes.

Production and Properties.—The process used for extraction of cobalt from speiss is essentially the same whatever the origin of the ore. A good speiss should contain enough cobalt sesquioxide to yield sufficient chlorine with hydrochloric acid to oxidize all the arsenic to arsenate, and sufficient iron to combine with all the arsenic to form ferric arsenate, which is precipitated with milk of lime. Lead, bismuth and copper, if present, are removed as sulphides by saturation with sulphuretted hydrogen. The resulting solution is oxidized and fractionally precipitated with bleaching-powder liquor, cobalt being precipitated first as sesquioxide, leaving nickel chloride in solution. The nickel may then be removed as dioxide by further addition of bleach liquor, or as carbonate by addition of washing soda solution. The black cobalt sesquioxide, thus obtained, is dried and extracted with dilute hydrochloric acid to remove traces of nickel, again dried, mixed to a stiff paste with starch and roasted in thin layers. The reduction to metal is effected partly by carbon from the starch and partly by carbon monoxide from the furnace gases.

Cobalt, a silver-white metal, slightly harder than iron or nickel, is magnetic at all temperatures up to $1,150^{\circ}$ C, and then becomes non-magnetic. The melting point is $1,480^{\circ}$ and the boiling point $2,415^{\circ}$, both temperatures being intermediate between the corresponding temperatures for nickel and iron. The density of the metal varies from about 8.7 to about 8.9. Cobalt in a finely divided condition occludes up to about 200 times its volume of hydrogen, which is readily given up again on heating to 200° in vacuo.

Polished cobalt is not appreciably affected by exposure to air or water, and is only superficially oxidized at a red heat. It dissolves in nearly all dilute acids evolving hydrogen, but is scarcely attacked by moderately concentrated nitric acid. It is not attacked by alkaline solutions or fused alkalis. Heated in chlorine, bromine or iodine vapour, the metal forms the blue dichloride, green dibromide or black di-iodide, respectively. At 500° in ammonia a nitride, Co_2N , is formed which decomposes into cobalt and nitrogen at 600° . The metal is obtained in a pyrophoric condition (spontaneously inflammable) by reduction of its oxides at 250° . The cold pyrophoric metal decomposes acetylene with incandescence, forming carbon, hydrogen and benzene. Finely divided cobalt, even when not pyrophoric, decomposes carbon monoxide above 350° , forming carbon and oxygen. At 150° under a pressure of upwards of 40 atmospheres, the reduced metal combines with carbon monoxide yielding the tetracarbonyl, $\text{Co}(\text{CO})_4$, in orange crystals, which decompose at 60° at atmospheric pressure by loss of one-quarter of their carbon monoxide to form the black tricarbonyl, $\text{Co}(\text{CO})_3$. At red heat the metal decomposes steam, and at 150° burns in nitric oxide to form cobaltous oxide, CoO .

Oxides.—Cobalt is known in three conditions of oxidation, represented by the oxides, CoO , Co_2O_3 and CoO_2 . A fourth oxide is also known, which crystallizes in black octahedra, Co_3O_4 , or CoO , Co_2O_3 or $\text{Co}(\text{CoO}_2)_2$, and resembles the spinels in form and composition. The ordinary salts of commerce are cobaltous salts derived from the monoxide. A few simple and many complex salts are known derived from the sesquioxide. The dioxide gives rise to a few complex salts, and has slight acidic properties, combining with bases to form cobaltites, such as MgCoO_2 . Cobalt thus possesses at least four valency electrons, of which two are relatively feebly bound and give rise to cobaltous salts. In the bivalent condition cobalt has slight basic properties, the salts having an acidic reaction and being slightly hydrolysed by water. This accords with its position as a transition element of the 4th period. (See PERIODIC LAW.)

Salts.—The metal is occasionally found native and is never found combined in nature with a higher valency than two. Cobaltous salts of nearly all the known acids have been prepared, of which the chloride, nitrate, sulphate, carbonate, acetate and linoleate are in fairly extensive commercial use. Nearly all soluble cobaltous salts are red in the hydrated condition, while the insoluble salts are usually pink. On dehydration many of the red salts assume an intense blue colour, and this fact is made use of in the preparation of "sympathetic" inks. The hydrated sulphate,

cobalt vitriol, is a noteworthy exception, the anhydrous salt being pink. Most cobaltous salts combine with ammonia forming hexammines, for example $[\text{Co}(\text{NH}_3)_6]\text{Cl}_2$, though pentammines and tetrammines are also known. Similar complex compounds are formed with many organic bases. A very large number of cobaltous double salts are known, such as double sulphates, double nitrates, double carbonates and double cyanides. Potassium cobaltous sulphate belongs to the series $\text{R}''\text{SO}_4 \cdot \text{R}'_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$, where R'' may be Co, Fe, Mn or Cr. Double nitrates of the form $\text{Co}_2\text{R}_2(\text{NO}_3)_{12} \cdot 24\text{H}_2\text{O}$ have been used in the separation of the trivalent "rare earth" elements. Potassium cobalto-carbonate, $\text{K}_2\text{Co}(\text{CO}_3)_2 \cdot 4\text{H}_2\text{O}$, forms a pink solution in water, which becomes blue on heating, the pink colour returning on cooling. Potassium cobaltocyanide, $\text{K}_4[\text{Co}(\text{CN})_6]$, decomposes water on boiling with liberation of hydrogen and formation of caustic potash and cobaltcyanide, $\text{K}_3[\text{Co}(\text{CN})_6]$. On rapid oxidation by air, the cobaltcyanide yields hydrogen peroxide, caustic potash and the cobaltcyanide, but on slow oxidation no hydrogen peroxide results, any hydrogen peroxide formed being utilized to oxidize the cobaltcyanide.

Almost the only simple cobaltic salt that is known is the fluoride, CoF_3 , a green powder, decomposed by water to form brown cobaltic hydroxide. Cobaltic double and complex salts are, however very numerous. The alums, as $\text{K}_2\text{SO}_4 \cdot \text{Co}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$, form blue octahedra, which are unstable in solution and yield cobaltous and alkali sulphates and oxygen. The cobaltinitrites of the stronger bases only are known. The sodium salt is freely soluble in water, whereas the potassium, ammonium and barium salts are insoluble. Sodium cobaltinitrite is used as a test for potassium, yielding with potassium salts very insoluble yellow precipitates of the disodium potassium salt, $\text{Na}_2\text{K}[\text{Co}(\text{NO}_2)_6]$, or the sodium dipotassium salt, $\text{Na}_2\text{K}_2[\text{Co}(\text{NO}_2)_6]$. The tripotassium salt cannot be obtained in the presence of sodium salts. The cobaltcyanides are much more stable than the cobaltocyanides, or even the ferro- and ferricyanides. On treatment with concentrated acids, the cobaltcyanides are not decomposed but yield the complex acid, hydrogen cobaltcyanide, $\text{H}_3[\text{Co}(\text{CN})_6] \cdot \text{H}_2\text{O}$, which is colourless and becomes anhydrous at 100° C. Cobaltcyanides of nearly all the metallic bases have been prepared, including those of the "rare earth" metals. Yttrium may be separated from erbium owing to the fact that the yttrium salt is about thrice as soluble as the erbium salt.

On treatment of cobaltous salts with an oxidizing agent in the presence of ammonia, complex cobaltic amines are formed. Cobaltous chloride, for example, dissolved in excess of ammonia solution, is oxidized by hydrogen peroxide in the presence of ammonium chloride to form a mixture of cobaltammines, in which the number of ammonia molecules per atom of cobalt varies from four to six, pentammines predominating. If much ammonia is present, the two tetrammines, $[\text{CoCl}(\text{H}_2\text{O})(\text{NH}_3)_4]\text{Cl}_2$ and $[\text{Co}(\text{H}_2\text{O})_2(\text{NH}_3)_4]\text{Cl}_2$, are converted, on warming, into pentammines. The main product consists of the three pentammines, purpureo-cobalt chloride, $[\text{CoCl}(\text{NH}_3)_5]\text{Cl}_2$, roseo-cobalt chloride, $[\text{CoH}_2\text{O}(\text{NH}_3)_5]\text{Cl}_2$, and hydroxo-purpureo-cobalt chloride, $[\text{CoOH}(\text{NH}_3)_5]\text{Cl}_2$. The roseo and hydroxo salts are both converted into the purpureo salt if much ammonium chloride be present and the liquid be boiled. The hexammine, $[\text{Co}(\text{NH}_3)_6]\text{Cl}_2$, luteo-cobalt chloride, is invariably present to the extent of 2 or 3% and becomes the chief product if the reaction takes place under a pressure of a few atmospheres. In the foregoing series of amines, the ammonia may be replaced by equivalents of ethylenediamine and other organic bases and the chlorine by other acid radicals. Cobaltic diammines and triammines are also known, particularly in combination with the nitrite radical, for example, ammonium diamminocobaltinitrite (Erdmann's salt), $\text{NH}_4[\text{Co}(\text{NH}_3)_2(\text{NO}_2)_4]$, and triaminocobaltic nitrite, $\text{Co}(\text{NH}_3)_3(\text{NO}_2)_3$, which does not give rise to any ions on solution.

In all complex cobaltic compounds six non-ionizing groups can be discerned attached or co-ordinated to the cobalt atom, which is accordingly said to possess the co-ordination number six. (See AMMINES.) Some of these co-ordinated compounds have been shown to be capable of existing in optically-active, isomeric

forms, proving, as in the case of carbon, that the valency directions are not planar but spatial. In the case of carbon, the attached atoms or groups are disposed tetrahedrally about the carbon atom, and give rise to optically active isomerides according to the laws of symmetry. In the case of cobalt, the disposition of groups about the cobalt atom is octahedral, and as many as five isomeric forms have been proved to exist for certain co-ordinative groupings. (See also STEREOCHEMISTRY.)

Detection and Estimation.—Cobalt can be detected, even in very minute amounts, by the formation of an intensely blue borate on heating a cobalt salt in a borax bead. In solution, cobaltous salts can be detected by the green colour resulting on treatment with sodium bicarbonate and hydrogen peroxide, and by the red colour or precipitate resulting on treatment with an acetic acid solution of α -nitroso- β -naphthol. In group analysis, cobalt is precipitated as sulphide by means of ammonium sulphide. It may be separated from nickel owing to the fact that cobaltcyanides are stable to hypobromites, whereas nickelocyanides are decomposed by hypobromites to form nickel dioxide. The intense blue colour and solubility of cobaltous thiocyanate in organic solvents may be used as a test for cobalt. The solubility of sodium cobaltinitrite and the insolubility of the potassium salt may be used as a test for either potassium or cobalt. After separation from other metals, cobalt may be precipitated as oxide by persulphates or hypobromites, as sulphide by ammonium sulphide, or as carbonate. When estimated by the α -nitroso- β -naphthol method, the precipitate may be dried and weighed, but in the other cases it is usual to ignite to sulphate with sulphuric acid, or to ignite and reduce to metal with pure hydrogen. The anhydrous sulphate method when available (in the absence of non-volatile metals and non-volatile acids) is rapid and accurate. Cobalt may also be estimated after electro-deposition from an acid solution of the double ammonium sulphate. The thiocyanate test has been adapted for the colorimetric estimation of small amounts of cobalt.

Uses.—Metallic cobalt is used industrially in the manufacture of ferrous and non-ferrous alloys. In some cases cobalt speiss is smelted directly to yield a ferro-nickel-cobalt alloy, which is used in the manufacture of special steels. Steels containing much cobalt and tungsten are used in the manufacture of permanent magnets for telephony and other purposes. Non-ferrous alloys, containing over 50% of cobalt with varying amounts of tungsten, chromium and occasionally molybdenum, are used in the production of high-speed cutting tools, which retain their hardness at a red heat. The high-speed tool alloy, stellite, has a composition approximating to cobalt 55, tungsten 15 to 25, chromium 15 to 25, and molybdenum 5%. Cochrome is a ferrous alloy containing cobalt 60, chromium 14 to 16, iron 14 to 16%, similar to nichrome in composition and properties but with cobalt instead of nickel. It is used for electrical heating elements. Cobalt compounds are used to an increasing extent in industry, the linoleates, oleates, resinates and acetates being used as "driers" in the paint and varnish industry. Smalt is a complex potash aluminium cobalt silicate or glass, made by roasting impure cobalt oxide with quartz and potassium carbonate. It is a valuable and very permanent pigment of an intense blue colour. Potassium cobaltinitrite has long been used as an artists' pigment of great stability under the name of cobalt yellow. This pigment has also been used in the ceramic industry for producing a pure blue colour on porcelain after baking. Cobalt oxide, alone and in conjunction with other oxides, is in common use in the production of blues, purples, yellows and reds in the china trade. Cobalt ultramarine consists of the oxides of cobalt, aluminium and zinc; cobalt green of cobalt and zinc oxides; turquoise green of cobalt, zinc and chromium oxides; and cobalt red of cobalt and magnesium oxides.

Cobalt compounds have no therapeutic value and are non-toxic, the toxicity even of the complex cobaltamines being no greater than that of the ammonia they contain.

See J. N. Friend, *Text-book of Inorganic Chemistry*, vol. ix., part 1 (1926). (J. D. M. S.)

COBALTITE, a mineral with the composition CoAsS, cobalt sulpharsenide. It is found as granular to compact masses, and

frequently as beautifully developed crystals, which have the same symmetry as the isomorphous mineral pyrite, being cubic with parallel hemihedrism. The usual form is a pentagonal-dodecahedron with faces of the cube and octahedron. The colour is silver-white with a reddish tinge, and the lustre brilliant and metallic, hence the old name cobalt-glance. The brilliant crystals from Tunaberg in Sodermanland, Sweden, and from Skutterud near Drammen in Norway are well known in mineral collections. Crystals have also been found at Khetri in Rajputana, and under the name *sehta* the mineral is used by Indian jewellers for producing a blue enamel on gold and silver ornaments.

COBAN, a city of Guatemala, Central America, capital of the department of Alta Verapaz and a centre of the coffee trade. Population, about 23,000. Coban is 105m. N. of Guatemala City, although no railway or motor highway joins the two. It is reached by launch from Puerto Barrios through Lake Izabal and thence by the Alta Verapaz railway and finally by highway. It is a rich area in the production of coffee, a large number of German and a lesser number of British interests being the owners of the best producing properties.

COBB, HOWELL (1815–1868), American political leader, was born at Cherry Hill, Ga., on Sept. 7, 1815. He graduated from Franklin college (University of Georgia) in 1834, and in 1836 was admitted to the bar. From 1837 to 1840 he was solicitor-general for the western circuit of his State. In 1843–51 and in 1855–57 he was a member of the national House of Representatives, becoming Democratic leader in that body in 1847, and serving as speaker in 1849–51. From 1851 to 1853 he was governor of his State; and from 1857 to 1860 he was secretary of the Treasury in President Buchanan's cabinet. In 1861 he was appointed colonel of a regiment and two years later was made a major-general in the Confederate army. He sided with President Jackson on the question of nullification; was an efficient supporter of President Polk's administration during the Mexican War; and was an ardent advocate of slavery extension into the Territories, but when the Compromise of 1850 had been agreed upon he became its staunch supporter as a Union Democrat, and on that issue was elected governor of Georgia by a large majority. In 1860, however, he ceased to be a Unionist, and became a leader of the secession movement. He died in New York city on Oct. 9, 1868.

See W. B. Phelps (ed.), "The Correspondence of Robert Toombs, Alexander H. Stephens and Howell Cobb," *Am. Hist. Assoc., Annual Report*, vol. ii. (1911).

COBBE, FRANCES POWER (1822–1904), British social writer and author, was born in Dublin on Dec. 4, 1822, of a family many of whose members had held high positions in the Church. She was educated privately, and her first book, *The Theory of Intuitive Morals*, was published anonymously. In 1858 she began social work among the girls and boys of Bristol. She spent much time abroad, and began to contribute to the newspapers and reviews, carrying out various special investigations on vivisection, of which she was all her life a violent opponent, on destitution, and on separation orders and divorce. She was a strong suffragist. From time to time she conducted services in Unitarian chapels. She published about 30 separate works, among which may be mentioned: *The Duties of Women* (1881; new ed., edit. Blanche Atkinson, 1905), and her own *Life* (2 vols., 1894; new ed., edit. Blanche Atkinson, 1904).

COBBETT, WILLIAM (1763–1835), English author, journalist and Radical, is one of the most representative figures in English literature, and his life and writings embody the history of the common people between the revolutions of the eighteenth century and the dawn of the Victorian era. He was born at Farnham, Surrey, on March 9, 1763 (not 1766, as he himself wrongly stated). His father was a small farmer; and his grandfather had been a day-labourer. As a boy, he worked in the fields, but, at 14, began his adventures by running away from home and getting work in Kew Gardens. He returned home after a while; but, at 19, after an unsuccessful attempt to join the Navy during a visit to Portsmouth, again left Farnham and, going to London on a sudden impulse, found employment as a solicitor's clerk.

Soon sickening of this occupation, he went down to Chatham, meaning to enlist in the Marines, but found himself in a line regiment instead. After a year at the depot, during which he read hard and discursively and taught himself grammar and writing, he was drafted, as corporal, to Nova Scotia, where his regiment was stationed. Soon, however, he was shifted to Fredericton, New Brunswick, where he remained till 1791, rising rapidly to the position of regimental sergeant-major. This position made him conscious of the systematic fraud and speculation which went on in the regiment—as indeed throughout the service—and he set to work to collect evidence against the principal offenders. At length, in 1791, his regiment was ordered home; and he at once procured his discharge, with excellent testimonials. Having done this, he immediately set about bringing the defaulters to book, and demanded a court-martial of the officers against whom he had collected evidence. This was at length granted; but Cobbett was unable to secure the discharge of his essential witness, or to get the regimental books impounded for safekeeping. In despair of getting the case fairly heard, he failed to appear at the court-martial, and fled to France in March 1792. He had married Ann Reid, to whom he had become engaged some years before in New Brunswick, while he was awaiting the court-martial proceedings; and she joined him in France. He remained there until the late summer of 1792 when, seeing the outbreak of war to be imminent, he took ship for America. There, first at Wilmington and later at Philadelphia, he supported himself by teaching English to the French *émigrés*, who were reaching the United States in large numbers.

So far Cobbett had written little. In the army, he had composed a grammar for the use of private soldiers; but this was not published. He had also almost certainly a hand in a pamphlet exposing army abuses, published in 1793 under the title of *The Soldier's Friend*. But in 1794 occurred an incident which really embarked him on his long career as a political writer. Joseph Priestley, the great Unitarian Radical, came in that year to settle in the United States, and numerous addresses of welcome were presented to him by American Radical societies. These aroused Cobbett's strong pugnacious instincts; and he entered the lists as a pamphleteer with his *Observations on Dr. Priestley's Emigration* (1794). From that date until his return to England in 1800, he was the most vehement and violent writer on the British side in the United States, producing a series of tirades against the French Revolution and all its works, and against all Americans who ventured to give it, or any sort of Radicalism, even the mildest support. *A Bone to Gnaw for the Democrats*, *A Kick for a Bite*, *The Scare-Crow*, *The Cannibal's Progress* (an account of the horror of the French Revolution), and a scurrilous *Life of Tom Paine*, are among these early pamphlets. They are all unmeasured in violence, and often outrageous, but always lively, readable and written in really virile and forthright English. Cobbett's style was almost as good in his first unpracticed writings as in the best of his more famous later work. Pre-eminent among these early pamphlets is his autobiographical *Life and Adventures of Peter Porcupine* (the highly apposite name under which he had chosen to write) in which he defended himself against those who abused him by an account of his upbringing and early career. This pamphlet is one of the best of all his writings. He also supplemented his pamphleteering with a regular newspaper, *Porcupine's Gazette*.

Cobbett was soon in trouble with the law. He libelled Dr. Rush, doctor and well-known Democratic politician, accusing him of killing George Washington with his special "bleeding treatment." This brought a heavy fine, and he then wrote scurrilous pamphlets about McKean, the judge who had tried the case, and was Rush's political ally. Before long he made the United States too hot to hold him, and in 1800 he gave up the contest and returned to England, where his writings, regularly republished, had already made him well known. He was greeted with enthusiasm as a powerful recruit to jingo journalism. He met Pitt at dinner, and was offered the editorship and ownership of one of the leading Government newspapers. He refused the offer, as he had already refused Government payment for his services in America,

and attempted instead to start a daily newspaper of his own, *The Porcupine*. This speedily failed; but in 1802, with help from Dr. Laurence and William Windham, who was for some years his chief political supporter, he started the weekly *Political Register*, which he thereafter edited, and for the most part wrote, regularly until his death in 1835.

The *Political Register*, with which Cobbett's name was always from 1802 chiefly associated, began its career as an extreme anti-Jacobin journal. It strongly opposed Addington and the Peace of Amiens, and called loudly for a renewal of the war with France. But after Pitt's return to power and the renewal of the war, Cobbett slipped gradually into opposition, and found himself in alliance with Windham and with Fox, the latter of whom he had hitherto vehemently denounced. In 1806, in the Ministry of All the Talents, his friends came to power; but Cobbett soon fell into opposition to them also. He was by this time denouncing the "Pitt system" as the root of all evil, and attacking in particular the methods of pursuing the war, the multiplication of pensions and sinecures, and the dangerous growth of the National Debt. When the Ministry of All the Talents broke up in 1807, he was already definitely a Radical, at war equally with Whig and Tory, and beginning to cry out for peace and parliamentary reform as well as for "economical reform."

So far, Cobbett was merely an outstanding political journalist, whose writings, however trenchant, had given little indication of his peculiar quality as a democratic leader. But from about 1805 a new tone begins to appear in his work. From 1800 to 1805 he had lived in London; but in the latter year he bought a substantial farm at Botley, near Southampton, and spent most of his time in the country. The change opened his eyes to the great contrast between the countryside as he remembered it in his boyhood and as it had become under stress of war-time prices and enclosure. He realized for the first time the misery of the labouring classes, the effects of the Speenhamland system of poor relief, of the enclosure movement, of the great revolution in agrarian conditions that was then at its height. It roused his indignation—the indignation of one who was himself by nature and nurture a yeoman. It completed his conversion to Radicalism, which he expressed as the cause of the dispossessed and suffering labourers of rural England.

Cobbett, the one articulate voice among the suffering people of the countryside, brought a new note into Radical agitation. At once, he became a power. But his power brought penalties. In 1809 there was a minor mutiny among the soldiers at Ely, over unfair deductions from pay. The mutiny was suppressed, and the ringleaders were flogged under the eyes of German mercenaries. Cobbett wrote, denouncing the floggings, and was prosecuted for sedition. A fine of £1,000, two years in Newgate gaol, bail in £3,000 and the finding of two sureties at £1,000 each, were his punishment.

From Newgate, under the lax prison discipline of the time, Cobbett continued to edit the *Register*, and wrote his famous *Paper against Gold*, in which he denounced the war-time inflation of the currency, and the financial policy of Pitt and his successors. His imprisonment, however, brought him financial ruin. He went bankrupt. His farm at Botley was sold; and most of his valuable properties passed out of his hands. The *Register* he barely saved. Three great publishing enterprises on which he was engaged had to be sold—the *State Trials* (known as Howell's, from the editor whom Cobbett employed), the *Parliamentary History of England*, and the *Parliamentary Debates*, which were bought by his printer, Hansard, and thereafter bore the latter's name. All these were originated by Cobbett, though the actual editorship, under his control, had been mainly left to others.

When Cobbett emerged from prison in 1812, he appeared to be ruined. But he had still the *Register*, and the ending of the war, in 1815, brought him his chance. Prices fell, indeed; but the cessation of war demand and the prostration of Europe after the long struggle led to widespread unemployment and distress. In the industrial districts, unrest grew; and the farmers, pressed down by high taxation, were also in a condition of active discontent. The Government had no plans for dealing with the crisis;

and Cobbett with his demands for parliamentary reform and a reduction of the heavy interest on the National Debt, became the central figure in a nation-wide agitation. In 1816, he began the issue of a cheap unstamped *Register* (denounced as Cobbett's "two-penny trash") addressed particularly to the journeymen and labourers of the Northern and Midland counties. He became suddenly the most influential leader of the working classes. But by this time the Government, alarmed at hunger-riots and movements of despair and discontent, was embarking on a campaign of repression which recalled Pitt's measures in the years following the French Revolution. In 1817 Lord Sidmouth, the Home Secretary, passed his "Gagging Bills" and procured the suspension of the Habeas Corpus Act. Widespread arrests of Radical leaders followed; and Cobbett, in order to avoid arrest, fled to the United States, where he remained until 1819.

Settling down on a hired farm at North Hempstead, Long Island, Cobbett set himself to write. He sent the copy regularly for the *Political Register*, which continued to be published by his agents in England. But he also embarked on other literary work. To the respite which exile gave him from daily political preoccupations we owe the beginning of his great literary period. Hitherto he had written much excellent journalism, but no important book. But between 1817 and 1819 he produced not only his *Journal of a Year's Residence in the United States of America*, but also his famous *Grammar of the English Language*, which, despite its faults of scholarship, is still probably the best introduction to correct virile English for the working-class student. In America, too, he projected certain others of the important books which he produced, from this time onwards, with profuse mental vigour.

Although the repression was by no means over—indeed, the "Six Acts" were not passed until after his return—Cobbett came back to England late in 1819, and assumed his place as the outstanding leader of working-class radical agitation. From 1819 to 1832 his history is, in one aspect, the history of the agitation for parliamentary reform. But he found scope for other activities as well, above all for his well-known *Rural Rides* through the southern half of England. His accounts of these appeared in the *Register* between 1820 and 1830, in which year they were first published in book form.

Rural Rides, certainly Cobbett's best widely read book except the *Grammar*, are difficult to describe. They are, in part, a plain account of what he saw in the English countryside—of good farming and of bad, of rotten boroughs and the country houses of bankers, stock-jobbers and successful army contractors, and above all of the misery and starvation of the common people. But they are far more than this. They abound in digressions, in racy snatches of autobiography, in topical political tirades, and everywhere in abundant outflowings of Cobbett's own forceful and appealing personality. Though they were composed in haste and sent off to the *Register* without chance of revision, they were astonishingly well written. *Rural Rides* are Cobbett at his best, showing more sides of the man than appeared in any other of his works.

But *Rural Rides*, and the ceaseless "rustic harangues" which accompanied them, did not, even with the added burden of conducting the *Register* and actively guiding a large section of the reform movement, at all exhaust Cobbett's energies. Books, and mostly good books, flowed from him—*Cottage Economy* and the *Sermons* in 1822, *The History of the Protestant Reformation in England* (questionable history this, but vigorous writing) in 1824–26, *The Woodlands* in 1825, *Advice to Young Men* (next to *Rural Rides* his best book) and *The English Gardener* in 1829, and a host of others. Moreover, in 1820–21 he whole-heartedly espoused the cause of Queen Caroline against the king, acted as one of her regular advisers before the famous trial, and wrote ceaselessly on her behalf. He even composed a number of her own letters and messages concerned with the case. And in his hands the defence of the Queen became also a means of rallying the forces of the Reformers.

Meanwhile, in 1820, he had rid himself by bankruptcy of some of his financial worries, and had settled down to rebuild his shat-

tered fortunes by means of his pen. Botley had been given up, and for awhile he had no land. But soon he developed a flourishing seed-farm in Kensington, and began to deal also in American trees, and in a variety of imported seeds and plants. Especially he urged the cultivation of maize ("Cobbett's corn"), of the locust tree, and of Swedish turnips, as well as the introduction of the straw-plait manufacture from home-grown grasses. His seed-farm and his agricultural writings brought him a large following among the farming classes.

In 1830, with the fall of Wellington and the end of the long period of Tory ascendancy, the reform agitation came to a head. The Whigs, under Lord Gray, assumed office, and reform became the one political question of the day. Immediately upon this change followed the hunger movement of the rural labourers in the southern and eastern counties, known as "the last labourer's revolt." The opponents of the movement sought to trace these troubles to Cobbett's influence, and the Whig Government, anxious to prove its respect for property and to reassure the propertied classes as the subject of reform, prosecuted him. Refusing to employ counsel, Cobbett defended himself in a masterly speech, which thoroughly turned the tables on his opponents. The jury disagreed, and no further attempt was made to molest him. The revolt, however, was savagely repressed.

At length, in 1832, the Reform Act became law. Cobbett, though he had no love for the Whigs, had urged the workers to support it, on the ground that no more liberal measure stood any chance of immediate success. At the election which followed he was elected M.P. for Oldham, as the colleague of John Fielden, the Radical manufacturer. He had stood at Manchester also, but withdrew on learning of his success at Oldham.

This was not Cobbett's first parliamentary contest. He had stood unsuccessfully for Coventry in 1820 and for Preston in 1826. Indeed, for many years he had been seeking to force his way into parliament. At sixty-eight years of age, he found himself a member, as strongly in opposition to the reformed parliament of 1832 as he could have been to the unreformed parliaments of earlier years. His two and a half years of parliamentary life he passed as the leader of a tiny group of extreme radicals, supported sometimes by O'Connell and his Irish, but always fighting for forlorn hopes. Especially, he put up an unavailing struggle against the "new poor law" of 1834, and his last weeks of life were spent in the endeavour to run a campaign against the act when it had been passed into law.

It is usually said that Cobbett was not a success as a parliamentarian. He could hardly have been so, for he accepted none of the rules of the game. He remained to the end the leader of an essentially extra-parliamentary crusade. But already his health was failing. He had been always an indefatigable worker, rising very early and doing a good part of a day's labour before other men were astir. Now severe colds and coughs began to trouble him; but he insisted on adding assiduous attention to his parliamentary duties to his other multifarious activities. In 1835 his health gave way under the strain, and, on June 18, he died of an attack of influenza. His sons attempted for a few months to carry on the *Register*; but it was nothing without his vigorous editorials, and was speedily discontinued.

Cobbett was survived by his wife and by seven children. Anne, the eldest (1795–1877), wrote *The English Housekeeper* and other works. Both she and the two other daughters, Eleanor and Susan, remained unmarried. The three eldest sons all went to the bar. William (1798–1878) wrote *The Law of Turnpikes* and other legal works, and edited the *Register* for a while after his father's death. John Morgan (1800–1877) wrote several books, stood unsuccessfully for Oldham in 1835, and successfully, as an Independent, in 1852. He held the seat till 1865, and again, as a Conservative, from 1872 to 1877. He married John Fielden's daughter in 1851. James Paul (1803–1881) wrote *A Ride in France*, *Journal of a Tour in Italy*, etc., and stood for Bury as a Radical in 1837. Richard Baverstock Brown, the youngest son (1814–1875) became a solicitor in Manchester, and was active there in the Chartist movement.

Cobbett's character has been variously estimated. He was

always extremely pugnacious, and made many enemies. But he made also many firm friends. His pugnacity, which led him to quarrel, almost as much with allies as opponents, was purely political. Carlyle called him "the pattern John Bull of his century"; his fellow M. P., Buckingham, said that he had "a ruddy countenance, a small laughing eye, and the figure of a respectable English farmer." Hazlitt, who liked his books, also said he looked like a farmer. Cobbett was, indeed, despite his appeal to the workers of the factory districts, always at heart a countryman, with an unconquerable instinct for the land and the men of the land. He was intensely English, and, in his way, intensely patriotic; and it was this patriotism that roused him to the defence of his fellow-countrymen, trodden under by the oppressions of war and the twin revolutions in agriculture and industry whose devastating social effects he watched from phase to phase. He was that rarest of literary portents—an articulate peasant. His prose is astonishingly quick in its movement, and yet solid as a lump of earth. His clods of abuse and denunciation stick to-day. He had a marvellous facility for nicknames, and for the ridicule that hurts. But above all his prose depends for its success on the personal quality that pervades it. It is spoken rather than written down; and in it the man lives. *Rural Rides* and *Advice to Young Men* will be read as long as English is read at all. Cobbett has often been called an egoist, and he was; but his egoism—his capacity to make himself express the aspirations of a whole suffering class—is at the very root of his appeal.

BIBLIOGRAPHY.—Most of Cobbett's important writings have been mentioned above. Besides a host of pamphlets, his other books include *Porcupine's Works* (selections from his early American writings, in 12 vols., 1801); *A Collection of Facts and Observations relative to the Peace with Bonaparte* (1801); *Letters to Addington, in the Fatal Effects of the Peace with Bonaparte* (1802); *Letters to Lord Hawkesbury, on the Peace* (1802); *The Political Proteus* (an attack on R. B. Sheridan, 1804); *Letters on the Late War between the United States and Great Britain* (1815); *The Pride of Britannia Humbled* (New York, 1815); *Paper against Gold* (1815); *The American Gardener* (1821); *Collective Commentaries* (1822); *French Grammar* (1824); *The Poor Man's Friend* (1826); *A Treatise on Cobbett's Corn* (1828); *The Emigrants' Guide* (1829); *History of the Regency and Reign of George IV.* (1830); *Lectures on the French and Belgian Revolutions* (1830); *Spelling Book* (1831); *Tour in Scotland* (continuing *Rural Rides*, 1832); *Manchester Lectures* (1832); *Geographical Dictionary* (1832); *French and English Dictionary* (1833); *Four Letters to the Hon. John Stuart Wortley* (1834); *Life of Andrew Jackson* (1834); *Lectures on the Political State of Ireland* (1834); *Legacy to Labourers* (1835); *Legacy to Parsons* (1835); *Legacy to Peel*, (1836). Six volumes of selections from the *Register*, under the title, *Cobbett's Political Works*, were published in 1835-36.

Of the lives, the most recent is by G. D. H. Cole (1924). There are other lives by Huish (1836), E. Smith (1878), E. I. Carlyle (1904), and Lewis Melville (1913). (G. D. H. C.)

COBBOLD, THOMAS SPENCER (1828-1886), English man of science, was born at Ipswich in 1828, a son of the Rev. Richard Cobbold (1797-1877), the author of the *History of Margaret Catchpole*. From 1868 he acted as Swiney lecturer on geology at the British Museum until 1873, when he became professor of botany at the Royal Veterinary college, afterwards filling a chair of helminthology which was specially created for him at that institution. He died in London on March 20, 1886. His special subject was helminthology, particularly the worms parasitic in man and animals. His numerous writings include *Entozoa* (1864); *Tapeworms* (1866); *Parasites* (1879); *Human Parasites* (1882); and *Parasites of Meat and Prepared Flesh Food* (1884).

COBDEN, RICHARD (1804-1865), English statesman and economist, was born at Dunford Farm, near Midhurst, Sussex, the son of a small farmer, who died when Richard was a child. There were 11 children, who were befriended by relatives. Richard was sent to one of the bad private boarding schools of those days, in Yorkshire, and in 1819 became a clerk in his uncle's warehouse in Old Change, London. After serving in the warehouse he began to travel for the firm. In 1828 he joined with two friends in setting up business as calico merchants. Three years later the firm acquired a factory at Sabden, Lancs., and began to do their own calico-printing. This was the beginning of a business career which brought Cobden an independent fortune and permitted him in later years to devote himself, untrammelled by

financial difficulties, to his life work for greater freedom of trade. He remedied his lack of education by a course of serious study and by travel in the United States (June-Aug. 1835) and in the Near East (1836-37), in Germany (1838) and elsewhere, making full use of his opportunities of studying the economic and financial systems of the countries he visited. At this time he published two pamphlets which show that the broad lines of his ideas on foreign policy were already matured. These are *England, Ireland and America* (1835), by "a Manchester Merchant," in which he maintained that England had no interest in defending Turkey against Russia; and *Russia* (1836), in which he attacks the doctrine of the balance of power.

In October 1838 a group of seven Manchester merchants met to form an association to promote a movement for the abolition of the corn laws (*q.v.*). This became the nucleus of a national association, the Anti-Corn-Law league. From the beginning Cobden was the moving spirit in the league. Though other great names were associated with it, Cobden's was the directing mind. He had already met John Bright in connection with a campaign for providing education for the mass of the people, and had drawn him into politics. Bright's eloquence moved thousands in the meetings organized by the league, but Cobden's counsels carried more weight among statesmen. Throughout the whole of this campaign Cobden linked up the question of free trade with that of peace and disarmament; he regarded liberty of commerce as a key to international solidarity. He entered the House of Commons for Stockport at the general election of 1841. Parliament met in August, and Sir Robert Peel moved a vote of censure on the Whig Government, which was carried on Aug. 28. The new administration proposed a modification of the corn law which altered the sliding scale of 1828 and reduced the duty. Villiers' annual motion for repeal was defeated. Cobden presented his case against the corn law in his first speech in the House during the debate on the address. His sincerity and his precise knowledge of the question in hand made a strong impression. He proved a redoubtable opponent of Peel's financial policy, and persistently opposed the reintroduction of income tax.

Cobden desired the minimum of interference in trade and industry. When Graham's Factory Bill was brought forward in 1844 he accepted the regulation of child labour but he protested against any "interference with the freedom of adult labour." He was less extreme than Bright in his individualism, but had no use for the early reformers of the terrible factory system of the day, because he would not accept the principle of Government intervention. On the other hand he ardently supported measures for the improvement of education, and supported Peel's proposal to augment the grant to the Irish Roman Catholic college at Maynooth, on the ground that the priests were the instructors of the people and should themselves be thoroughly educated.

Meanwhile Cobden worked incessantly for the Anti-Corn-Law league, speaking all over the country, and, with increasing force in the House of Commons itself. His most powerful speech was perhaps that made in the House on March 13, 1845, when Peel, who was expected to reply, is said to have crumpled up his paper and notes and said to Sidney Herbert, "You may answer this, for I cannot." Some members of the Peel Government had realized at the time of Peel's first budget that the next change in the corn laws must be their total repeal. The prospect of famine in Ireland at the end of the year made the change inevitable. On Dec. 5 Peel resigned. Lord John Russell, invited to form a cabinet, asked Cobden to take office, but he declined on the ground that his mission lay outside the House on the public platform. On the 20th Peel resumed office. The course of the events in the session of 1846 is related elsewhere (*see* PEELE). It is sufficient here to say that Peel's famous resolutions included a modified sliding scale of duties for three years, and that after Feb. 1, 1849, oats, barley and wheat should be admitted at a nominal duty of a shilling. The bill embodying this resolution was passed by the House of Lords on June 25, 1846. Four days later Peel resigned, not without a tribute to Cobden. "The name," he said, "which ought to be, and will be, associated with the success of these measures, is not mine, or that of the noble lord (Russell), but the name of one who,

acting I believe from pure and disinterested motives, has, with untiring energy, made appeals to our reason, and has enforced those appeals with an eloquence the more to be admired because it was unaffected and unadorned: the name which ought to be associated with the success of these measures is the name of Richard Cobden."

The seven years' struggle for repeal left Cobden a ruined man, for he had been compelled to neglect his own business. A subscription was raised for him to enable him to meet his obligations. With part of the amount provided he bought his birthplace, the farmhouse of Dunford, which was thenceforward his home. He spent 14 months abroad (Aug. 1846–Oct. 1847), visiting the chief countries of Europe and urging on the many public men by whom he was received the necessity of greater freedom of trade. He returned more than ever opposed to a policy of intervention in any shape or form in the political situation of Europe. He now turned to work for the promotion of peace and the reduction of armaments, the logical complement of free trade, and became a formidable opponent of Palmerston's general foreign policy. In the Parliament elected in 1847 he sat for the West Riding of Yorkshire. In that parliament he brought forward two important motions: one in favour of international arbitration (June 12, 1849), the other the mutual reduction of armaments (1851). He associated himself with the peace movement, at that time derided, and helped to organize a series of international congresses for the promotion of peace at Brussels, Paris, Frankfurt, London, Manchester and Edinburgh between 1848 and 1851. The panic which took possession of a large section of Englishmen in 1851 on the foundation of the Second Empire in France put his principles to the test. By his resolute campaign against the scare-mongers this pamphlet, *1792 and 1853, in Three Letters* (1853), Cobden sacrificed the popularity he had won as the man who gave cheap food to the people. With Bright he withstood the torrent of popular sentiment in favour of war against Russia during the period before the Crimean War. He maintained strongly that the future of the Turkish provinces in Europe lay with the Christian populations and that England should be on their side and not on the side of the Turk. On Feb. 26, 1857, over the "Arrow" incident (Oct. 1856) in China, when Canton was bombarded on the ground that the Chinese had unlawfully boarded a ship of that name, Cobden brought in a motion condemning the action of Sir John Bowring in this matter, which was carried and led Palmerston to dissolve parliament. Cobden's peace policy had destroyed his electoral prospects. He was defeated at Huddersfield, and retired to his house in Sussex for the time, and then made a second visit to America.

On his return (June 29, 1859) he found he had been returned unopposed by Rochdale to the new parliament, and that the Whigs were once more united under Palmerston, who asked him to join his cabinet as president of the Board of Trade. This offer, generous from a man of whose policy he had been the stoutest opponent, was declined on the ground that consistency forbade it. Nevertheless Cobden was the organizer of one important achievement of the new ministry, the conclusion of the commercial treaty with France of 1860. He first discussed the feasibility of such a proposal with Gladstone, and then with Palmerston and Russell; from the two latter he received tepid encouragement, but was offered the assistance of the Paris embassy. He proposed to go to France to interview Napoleon III., and in fact, spent a year (Oct. 1859–Nov. 1860) in laborious and at first unofficial negotiations (he only received definite official powers in Jan. 1860) for a mutual reduction of tariffs in the interest of increased trade between France and England. His work for the conclusion of this commercial treaty is proof, if any were needed, that Cobden was not a merely negative advocate of a laissez-faire policy, but a practical and constructive statesman.

The last of the greater issues of policy in which Cobden was involved was the American Civil War. He had been a regular correspondent of Charles Sumner's since 1851, and though his hatred of war made him say frankly that he would not have gone to war for emancipation, he did, after some hesitation, declare for the North, and J. A. Hobson, writing of this correspondence,

asserts that he "did more than any other Englishman, save Bright, to correct the mistakes of fact and judgment which confused the issue in this country (Great Britain) at the outset, and to give sound counsel upon the sharp concrete cases which more than once brought us near to the breaking-point with the Federal Government."

Cobden died on April 2, 1865, in London of a chill contracted on a journey which he had insisted on taking in order to be present at a discussion on a scheme of Canadian fortification.

His distrust of Government at home and his limited belief in democracy were coupled with a firm belief in the good sense and worth of the middle classes. Starting from the belief that it was impossible to regulate wages by national considerations alone in industries competing in a world market he regarded trade unionism as an unjustifiable use of monopoly. He was a child of the industrial revolution, and he believed that the removal of restrictions on the free play of self-interest would bring to everyone his due share of the profits of industry. He opposed factory legislation for this reason, except in the case of children, for whom he realized that freedom of contract was in fact freedom of coercion. Nevertheless in his later years his confidence in the beneficial results of middle class domination began to be shaken, and the man who had written in 1842 (in a letter to F. W. Cobden) that trade unions were "founded upon principles of brutal tyranny and monopoly," wrote to William Hargreave in 1861, "Have they (the working people) no Spartacus among them to lead a revolt of the slave class against their political tormentors? . . . It is certain that so long as five millions of men are silent under their disabilities it is quite impossible for a few middle class members of parliament to give them liberty." But he was still thinking of the political rather than the industrial machine.

Cobdenism and what is called the Manchester School have fallen into some disrepute for various reasons, and in the criticisms launched on the school there is some danger of losing sight of the great services that Cobden rendered. His views on domestic and foreign policy were closely linked together. His experience convinced him that Government intervention in the affairs of foreign countries was nearly always bad; he believed in the minimum of Government at home and the minimum of intervention abroad. The subsequent controversy, still unsettled, was whether a too "spirited," or a too "passive" foreign policy would lead to the worse results. In the matter of international freedom of trade he was too optimistic. He believed that other countries would follow the English logic. He did not foresee the almost universal strength of economic nationalism, the enormous change in the whole structure of the economic world since brought about by gigantic foreign investments, with the development of new countries by the wealthier nations; he did not foresee the international operation of capital. But in his advocacy of arbitration, disarmament and peace he was far in advance of his time, and his ideals, apart from questions of practical application in circumstances as then existing, are justified by enlightened opinion to-day.

See his *Speeches*, edit. John Bright and J. E. Thorold Rogers (1870); *Political Writings of Richard Cobden*, with introduction by Sir L. Mallet (1878); W. Bagehot, *Biographical Studies* (1881); John Morley, *Life of Richard Cobden* (1882); J. A. Hobson, *Richard Cobden* (1918), which contains Cobden's letters to Sumner, taken from the Sumner-Cobden correspondence preserved at Harvard.

COBET, CAREL GABRIEL (1813–1889), Dutch classical scholar, was born at Paris on Nov. 28, 1813. After travelling in Italy to study Greek mss., he was professor at Leyden (1846–1884). He died on Oct. 26, 1889. Cobet's special weapon as a critic was his consummate knowledge of palaeography, combined with rare acumen and wide knowledge of classical literature.

His works include:—*Prosopographia Xenophontea* (1836); *Observationes criticae in Platonis comici reliquias* (1840); *De Arte interpretandi Grammatices et Critices Fundamentis innixa* (1846), his inaugural address at Leyden; *Commentationes Philologicae* (1850–51); *Variae Lectiones* (1854); *Novae Lectiones* (1858); *Miscellanea Critica* (1876); *Collectanea Critica* (1878); observations of Dionysius of Halicarnassus (1877); professorial discourses (1852–60). Editions of *Diogenes Laertius* (1850); *Philostratus περί ζωγραφικῆς* (1859); speeches of Hyperides (1858–77) and Lysias (1863). He was the editor of *Mnemosyne*.

See an appreciative obituary notice by W. G. Rutherford in the

Classical Review, Dec. 1889; Sandys, *Hist. Class. Schol.* (1908) iii. 282.

COBH, Cove of Cork: see QUEENSTOWN.

COBHAM, a village of Kent, England, 4m. W. of Rochester. Pop. of parish (1921) 955. The church (Early English and later restored) is rich in ancient brasses (1320-1529), commemorating thirteen Brooke and Cobham families, and for its fine oak stalls. Cobham college, containing 20 almshouses, after the dissolution took the place of a college for priests, founded by Sir John de Cobham in the 14th century. The present Cobham hall is mainly Elizabethan.

The Cobham family was established here before the reign of King John. In 1313 Henry de Cobham was created Baron Cobham. From 1417 the barony lay dormant till revived in 1445. In 1603 Henry Brooke, Lord Cobham, was arraigned for participation in the Raleigh conspiracy, and spent the remainder of his life in prison, where he died in 1618. With him the title expired, and Cobham hall was granted to Lodowick Stewart, duke of Lennox, passing subsequently by descent and marriage to the earls of Darnley. The present Viscount Cobham (cr. 1718) belongs to the Lyttelton family (see LYTTLTON, 1ST BARON).

COBIA or **CRAB-EATER** (*Rachycentron canadus*), a very voracious game-fish, cosmopolitan in warm seas, the only genus of the family *Rachycentridae* which, according to G. A. Boulenger, is allied with the mackerel-like fishes. The fish is slender and somewhat pike-like, reaching a length of five feet. The head is flattened and the lower jaw projecting. The tail is strong and forked, the upper lobe slightly the longer. The soft dorsal fin is long and low; in advance of it about eight low, isolated spines constitute the spinous dorsal. The anal is almost as long as the dorsal. This fish is dark olive green above, shading into lighter brownish-green and silvery. On the sides two distinct dark stripes parallel each other, one from tip of upper jaw to tail; the other starting at the origin of the pectoral fin. (See FISH.)

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY
CRAB-EATER, ALSO CALLED SERGEANT FISH BECAUSE OF ITS STRIPES RESEMBLING A SERGEANT'S CHEVRONS

COBLE, a flat-bottomed fishing-boat, with deep-lying rudder and lug-sail, used off the north-east coast of England. The word is probably of Celtic origin, and connected with the root *ceu* or *cau*, hollow; cf. Welsh *ceubol*, a ferry-boat.

COBLENZ or **KOBLENZ**, a city and fortress of Germany, capital of the Prussian Rhine province, 57 m. S.E. from Cologne by rail, situated on the left bank of the Rhine at its confluence with the Moselle, whence its ancient name *Confluentes*, of which Coblenz is a corruption. Pop. (1925) 58,174.

The town was one of the military posts established by Drusus about 9 B.C. Later it was frequently the residence of the Frankish kings, and in 860 and 922 was the scene of ecclesiastical synods. In 1018 the city, after receiving a charter, was given by the emperor Henry II. to the archbishop of Trier (Trèves), and it remained in the possession of the archbishop-electors till the close of the 18th century. In 1249-54 it was surrounded with new walls and it was partly to overawe the turbulent townsmen that successive archbishops built and strengthened the fortress of Ehrenbreitstein (*q.v.*) that dominates the city. As a member of the league of the Rhenish cities which took its rise in the 13th century, Coblenz attained to great prosperity. In 1344 the Moselle was spanned by a Gothic freestone bridge of 14 arches. The town suffered greatly, however, in the wars of the 17th, 18th and 19th centuries. In 1688 the French bombarded the Altstadt, destroying the old merchants' hall (*Kaufhaus*), which was restored in 1725. In 1786 the elector of Trier, Clement Wenceslaus of Saxony, took up his residence in the town, and a few years later it became one of the principal rendezvous of the French *émigrés*. In 1794 Coblenz was taken by the Revolutionary army and, after the peace of Lunéville, it was made the chief town of the Rhine and Moselle department (1798). In 1814 it was occupied by the Russians, by the congress of Vienna it was assigned to Prussia, and in 1822 it was made the seat of government of the Rhine

province.

The city, down to 1890, consisted of the Altstadt (old city) and the Neustadt (new city), or Klemenstadt. The old city was triangular in shape, two sides being bounded by the Rhine and Moselle and the third by a line of fortifications. Here is the church of St. Castor, originally founded in 836 by Louis the Pious; the present Romanesque building was completed in 1208, the Gothic vaulted roof dating from 1408. In the old quarter, too, are the Liebfrauenkirche, a fine church (nave 1250, choir 1404-31) with late Romanesque towers; the castle of the electors of Trier, erected in 1280, which now contains the municipal picture gallery; and the family house of the Metternichs, where Prince Metternich, the Austrian statesman, was born in 1773. In the modern part of the town, the palace (Residenzschloss), built in 1778-1786 by Clement Wenceslaus, the last elector of Trier, contains some fine Gobelin tapestries. Coblenz is a principal seat of the Moselle and Rhenish wine trade. Its manufactures include pianos, paper, machinery, boats and barges, sugar, dyes and chemicals. It is an important transit centre for the Rhine railways and for the Rhine navigation. Immediately outside the former walls lies the central railway station, in which is effected a junction of the Cologne-Mainz railway with the strategical line Metz-Berlin.

Coblenz was bombed by the Allies in 1917 and 1918. After the Armistice the town and bridgehead were occupied by Allied troops under the Treaty of Versailles, the town forming the second zone to be evacuated after 10 years, should Germany fulfil her obligations (see RHINELAND). Coblenz was the seat of the Rhineland High Commission, and was occupied first by American troops and later (since Jan. 10, 1923) by French troops. In October 1923 Separatists proclaimed a Rhineland Republic and declared that they had been recognized as a *de facto* Government by the French high commissioner, but the movement had collapsed by February 1924.

COBOURG, the capital of Northumberland county, Ontario, Canada, on Lake Ontario and the Canadian National and Canadian Pacific railways, 70m. E.N.E. of Toronto. Pop. (1931) 5,834. It has a large, safe harbour, and steamboat communication with St. Lawrence and Lake Ontario ports, and is connected by ferry with Charlotte, New York. It contains car-works, foundries, and carpet and woollen factories, and is a summer resort, especially for Americans. Victoria university, formerly situated here, was removed to Toronto in 1890.

COBRA, the name applied to the poisonous Colubrine snakes of the genera *Naja* and *Sepeidon* which have the power of dilating the neck laterally to form a broad disc or "hood." The dilatation is brought about by the raising and pushing forward of the long anterior ribs, the elastic skin being stretched taut over the framework which they form. This type of hood is in marked contrast to the vertical expansion of the neck which many snakes (*e.g.*, boomslang and mamba) can produce and which is caused by the inflation of the wind-pipe. In all species, however, erection of the hood only occurs when the animal is annoyed or disturbed.

The genus *Naja*, containing about ten species, ranges from the Cape throughout Africa, Arabia and India to southern China, the Philippine islands and the Malay Archipelago; *Sepeidon*, with a single species, is confined to South Africa. Both genera are proteroglyphous, *i.e.*, with fixed poison fangs on the front of the upper jaw, and the bite of all the species is extremely dangerous. Accurate statistics of snake-bite mortality cannot be obtained, but it seems fairly certain that the common Indian cobra (*Naja naja tripudians*) is responsible for several thousand deaths annually. This regrettable state of affairs is due to several causes. As in all proteroglyphous snakes the venom acts directly on the nervous system and so is much more rapid in its action than that of the viperine and opisthoglyphous snakes, the toxicity of which is chiefly due to its power of destroying the blood corpuscles. In the past, despite a multitude of so-called cures and a widespread belief in the efficacy of "snake stones," no really effective treatment was available except immediate excision of the site of the bite; now efficient "anti-venines" are produced from the blood sera of animals which have been immunized by regulated doses of

venom. These anti-venines, however, must be administered hypodermically, the dose is large and to be effective for the bites of proteroglyphous snakes must be given immediately, conditions not easily obtained in most of the regions which cobras inhabit. Again, the food of these snakes consist chiefly of frogs, toads, small mammals and, less frequently, birds, and the prevalence of rats and mice frequently attracts them to the vicinity of villages and houses where they are more likely to come into contact with man. In India also, cobras are often regarded with so much superstitious reverence that no attempt is made to kill them.

The best known species is the common Indian cobra (*Naja naja tripudians*), which may reach a length of about 5½ ft. and which exhibits great variation in colour; typically it is yellowish to dark brown with a black and white spectacle-shaped marking on the hood, but all gradations between this form and specimens without any trace of such a mark are known. The king cobra or hamadryad (*Naja hannah bungarus*) is another oriental species; it is rarer than the common cobra, larger, reaching a length of about 12 ft., and feeds chiefly on other snakes. Like all the cobras it lays eggs, but unlike them, exercises some parental care; a definite nest of dried leaves is made and the parents remain in the vicinity of the nest until the eggs are hatched. In Africa there are several species, the hooded or Egyptian cobra (*Naja haje*) and the black-necked cobra (*Naja nigricollis*) being the most widely distributed. The spitting cobra or ringhals (*Sepedon haemachates*) is closely allied to the true cobras (*Naja*) and is notorious for its habit of "spitting" venom when annoyed. The mechanism of this "spitting" appears to be that by compression of the poison-glands the venom is forced out through the fangs and at the same time a blast of air is exhaled. This carries the liquid forward as a spray for a considerable distance and if it strikes a person in the eyes intense irritation is set up which results in temporary, and sometimes permanent blindness.

(D. M. S. W.)

COBURG, a town in Germany, in the republic of Bavaria, on the left bank of the Itz, 40 m. S.S.E. of Gotha. Pop. (1925) 24,701. Coburg, first mentioned in a record of 1207, was of considerable importance in the 15th and 16th centuries, and owed its existence to the castle and to its position on the great trade route from Nürnberg via Bamberg to the north. In 1245 the castle became the seat of the elder branch of the counts of Henneberg (Coburg-Schmalkalden). The countships passed to Otto V. of Brandenburg, whose grandson sold them to Henry VIII. of Henneberg. The castle, town and countship then passed by marriage into the possession of the Saxon house of Wettin. In the 17th century the castle was strong enough to stand a three years' siege (1632-35) during the Thirty Years' War. In 1835 it became the residence of the dukes of Saxe-Coburg. The town contains many interesting buildings. The ducal palace, known as the Ehrenburg, originally erected on the site of a convent by Duke John Ernest in 1549, was renovated in 1698 and restored in 1816. It contains a decorated hall, the court church and a picture gallery. In the market square are the mediaeval *Rathaus* and the Government buildings. In the Schloss-platz is the Edinburgh palace, built in 1881. The educational establishments include a gymnasium, founded in 1604. The *Zenghaus* (armoury) contains the ducal library and among other public buildings may be mentioned the *Augustenstift*, formerly the seat of the ministerial offices, and the *Marstall* (royal mews). The castle was completely restored in 1835-38 and now contains a natural history museum. The most interesting room is that which was occupied by Luther in 1530. The chief manufactures are machinery, baskets, glass, colours and porcelain. Iron-founding and saw-milling are also important, and

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

THE COBRA, WHOSE BITE CAUSES THOUSANDS OF DEATHS YEARLY IN INDIA. WHEN IT IS ABOUT TO STRIKE THE NECK IS DISTENDED AS SHOWN

there is trade in the cattle reared in the neighbourhood. For the princes of the house of Coburg see WETTIN and SAXE-COBURG.

COCA or **CUCA** (*Erythroxylon Coca*), a plant of the family Erythroxylaceae, the leaves of which are used as a stimulant in western South America. It resembles a blackthorn bush, and grows to a height of 8 feet. The branches are straight and the lively green leaves are thin, opaque, oval, more or less tapering at the extremities. A marked characteristic of the leaf is an areolated portion bounded by two longitudinal curved lines one on each side of the midrib, and more conspicuous on the under face of the leaf. Good samples of the dried leaves are uncurled, deep green on the upper, and grey-green on the lower surface, and have a strong tea-like odour; when chewed they produce a sense of warmth in the mouth, and have a pleasant, pungent taste. The flowers are small, and disposed in little clusters on short stalks; the corolla is composed of five yellowish-white petals, the anthers are heart-shaped, and the pistil consists of three carpels united to form a three-chambered ovary. The flowers are succeeded by red berries. The plants thrive best in hot, damp situations, such as the clearings of forests; but the leaves most preferred are obtained in drier localities, on the sides of hills. The leaves are considered ready for plucking when they break on being bent. The green leaves (*matu*) are spread in thin layers on coarse woollen cloths and dried in the sun; they are then packed in sacks, which, in order to preserve the quality must be kept from damp. The composition of different specimens of coca leaves is very inconstant. Besides the important alkaloid *cocaine* (*q.v.*) there are several other alkaloids. Coca leaves and preparations of them have no external action. Internally their action is similar to that of opium, though less narcotic.

COCAINE, one of a series of "cocaines," alkaloids (*q.v.*) occurring in the leaves of coca (*q.v.*), a shrub indigenous to Bolivia and Peru, but now chiefly produced by cultivation in Java.

Cocaine crystallizes from alcohol in colourless prisms, melting at 98° C; it has a specific rotation $[\alpha]_D -15.8^\circ$, and it is readily soluble in ordinary solvents except water. It is generally used in medicine as the hydrochloride but sometimes as the base, dissolved or suspended in oils or fats. It yields well-crystallized salts of which the hydrochloride, $C_{17}H_{21}O_4N \cdot HCl$, is the most important; this crystallizes from alcohol in short colourless prisms, melting at 200-202° C, and having a specific rotation $[\alpha] -67.5^\circ$. On hydrolysis with mineral acids or baryta, cocaine breaks up into *ecgonine* (tropine carboxylic acid), benzoic acid and methyl alcohol, so that cocaine is closely related to atropine (*q.v.*). It was synthesized in 1923 by Willstätter and Bode.

All the "cocaines" are found to be derivatives of a simple base, *ecgonine*, which contains both a hydroxyl ($-OH$) and a carboxyl ($-COOH$) group, the latter being esterified with methyl alcohol and the former with an acid group—benzoic acid in the case of cocaine, $C_{17}H_{21}O_4N$, and cinnamic or truxillic acid in the other natural "cocaines." In the process for the manufacture of cocaine the total alkaloids of Java coca leaves are hydrolysed to *ecgonine*, which is converted by esterification as described, so that most of the cocaine of commerce is a partially synthetic product.

Cocaine produces little or no action on the unbroken skin, but if it is injected subcutaneously, or applied to mucous membranes such as those of the mouth, eye, nose, complete anaesthesia is produced so that slight operations can be carried out painlessly. A 5 or 10% solution is sufficient to abolish pain and touch, but stronger solutions are required to abolish sensations of heat and cold. If cocaine be swallowed its anaesthetic properties act on the mucous membrane of the stomach; the sensation of hunger is deadened and, therefore, persons taking the drug by the mouth can go for a long period without feeling the want of food. The central nervous system is first stimulated and later depressed, the higher centres being affected first. Moderate doses increase the bodily and mental power and give a sense of calmness and happiness; fatigue is abolished. Long exhausting feats can be carried out under the greater bodily power produced and the inhabitants of Peru chew the coca leaves for this reason. A single large dose causes mental excitement, delirium, ataxy, with head-

ache and depression later.

Therapeutically, cocaine is very largely used by oculists to produce anaesthesia of the eye; it is also used to relieve pain locally in other parts such as the mouth, teeth, ear, larynx, etc. Widespread anaesthesia may be produced by injecting cocaine into the spinal canal; thus an injection between the third and fourth lumbar vertebrae will produce anaesthesia of the lower limbs and of the trunk as far up as the umbilicus. Anaesthesia begins in the extremities and spreads upwards, recovery starts at the umbilicus and works downwards. A cocaine spray is often used to spray the throats of sensitive persons before making a laryngeal examination.

In Europe it is practically never used for its restorative effect, only for its anaesthetic effect: it is not a food, the good it does being only temporary. See DRUG ADDICTION and NOVOCAIN.

COCANADA, a town of British India, administrative headquarters of the Godavari district of Madras, situated on the coast in the extreme north of the Godavari delta, about 315 m. N. of Madras. Pop. (1921) 53,348. Cocanada is the fourth port of Madras. The roadstead in Coringa bay is protected but shallow, so that steamers have to lie 7 m. out, and the entrance to the canal, where the piers and wharves are situated has to be constantly dredged. The town is connected by navigable channels with the canal system of the Godavari delta, and by a branch line with Samalkot on the East Coast railway. The chief exports are rice, cotton and oilseeds. The industries include rice and oil mills, tile and salt works and tobacco manufacture. The town contains a college, orphanage and training college.

COCCEIUS, the latinized name of Johannes Koch (1603-1669), Dutch theologian, who was born at Bremen, on Aug. 9, 1603. After studying at Hamburg and Franeker, where Sixtinus Amama was one of his teachers, he taught at Bremen and at Franeker, and in 1650 succeeded Fr. Spanheim the elder as professor of theology at Leyden. He died there on Nov. 4, 1669. His chief services as an oriental scholar were in the department of Hebrew philology and exegesis. As one of the leading exponents of the "covenant" or "federal" theology, he spiritualized the Hebrew scriptures to such an extent that it was said that Cocceius found Christ everywhere in the Old Testament and Hugo Grotius found him nowhere. He taught that before the Fall, as much as after it, the relation between God and man was a covenant. The first covenant was a "Covenant of Works." For this was substituted, after the Fall, the "Covenant of Grace," to fulfil which the coming of Jesus Christ was necessary. He held millenarian views, and was the founder of a school of theologians who were called after him Cocceians. His most distinguished pupil was the celebrated Campeius Vitringa. His most valuable work was his *Lexicon et Commentarius Sermonis Hebraici et Chaldaici* (Leyden, 1669), which has been frequently republished; his theology is fully expounded in his *Summa Doctrinae de Foedere et Testamento Dei* (1648).

His collected works were published in 12 folio volumes (Amsterdam, 1673-1675). See Herzog-Hauck, *Realencyklopädie*.

COCCIDIA, parasitic single-celled animals (Protozoa) characterized chiefly by their manner of reproduction. The individuals developed from the spores (sporozoites) are able to reproduce asexually, as well as sexually. For further particulars see PROTOZOA.

COCCULUS INDICUS, the commercial name for the dried fruits of *Anamirta Cocculus* (family Menispermaceae), a large climbing shrub, native to India. It contains a bitter poisonous principle, *picrotoxin*, used in small doses to control the night sweats of phthisis.

COCENTAINA, town, Spain: see under ALCOY.

COCHABAMBA, a central department of Bolivia, occupying a series of fertile valleys on the eastern slope of the great Bolivian plateau, bounded N. by the department of El Beni, E. by Santa Cruz, S. by Chuquisaca and Potosí, and W. by Potosí, Oruro and La Paz. Area, 25,288 sq.m.; pop. (1915) estimated 534,901. Its average elevation is about 8,000ft., and its mean monthly temperature ranges from 50° to 71° F., making it one of the most agreeable climatic regions in South America. The

rainfall is moderate (18in. per year, coming almost entirely from November to March) and the seasons are marked by rainfall rather than by temperature. Cochabamba is essentially an agricultural department, although its mineral resources are good and include deposits of gold, silver, copper and tungsten. Its temperate climate favours the production of wheat, Indian corn, barley and potatoes, and most of the fruits and vegetables of the temperate zone. Coca, cacao, tobacco and most of the fruits and vegetables of the tropics are also produced. Its forest products include rubber and cinchona. Lack of transportation facilities, however, has been an insuperable obstacle to the development of any industry beyond local needs except those of cinchona and rubber. The population is chiefly of the Indian and mestizo types, education is in a backward state, and there are few manufactures other than those of the domestic stage, the natives making many articles of wearing apparel and daily use in their own homes. Rough highways and mule-paths are the usual means of communication, but a railway from Cochabamba (city) to Oruro, 132m., now brings this isolated region into touch with the commercial world. The capital is Cochabamba; other important towns are Punata, Tarata, Totorá, Mizque and Sacaba.

COCHABAMBA, a city of Bolivia, capital of the department of the same name and of the province of Cercado, situated on the Rocha, a small tributary of the Guapay river. Pop. (1924) estimated 34,281, mostly Indians and mestizos. The city stands in a broad valley of the Bolivian plateau, 8,400ft. above sea-level, overshadowed by the snow-clad heights of Tunari, 127m. E.N.E. of Oruro, with which place it is connected by rail. The climate is mild and temperate, and the surrounding country fertile and cultivated. The city is well supplied with foreign goods, and enjoys a large part of the Amazon trade through some small river ports on tributaries of the Mamoré. The city is regularly laid out, and contains many attractive residences surrounded by gardens. It is an episcopal city (since 1847), containing many churches. Cochabamba was founded in the 16th century, and for a time was called Oropeza. It took an active part in the "war of independence," the women distinguishing themselves in an attack on the Spanish camp in 1815, and some of them being put to death in 1818 by the Spanish forces. In 1874 the city was seized and partly destroyed by Miguel Aguirre, but in general its isolated situation has been a protection against the disorders which have convulsed Bolivia since her independence.

COCHEM, a town of Germany, in the Prussian Rhine province on the Moselle, and 30 m. S.W. of Coblenz by rail. Pop. (1925) 3,662. It is situated at the foot of a hill with a feudal castle dating from 1051. Trade is in wines.

COCHIN, a feudatory state of southern India, in political subordination to Madras, with an area of 1,418 square miles. It is bounded on the north by British Malabar, on the east by British Malabar, Coimbatore and Travancore, on the south by Travancore, and on the west by British Malabar and the Arabian Sea. The state may be divided into three regions: (1) the eastern zone, consisting of broken forested portions of the western Ghats, which, gradually decreasing in height, merge into (2) the central belt comprising the uplands and plains that dip towards the backwaters along the coast (see COCHIN: town), beyond which lies (3) the western zone, forming the littoral strip. The low country is naturally flat and swampy, but has been drained and cultivated. An undulating country with grassy hills, naked hills and wooded terraces, intersected by numerous torrents, and dotted with homesteads, orchards and cultivated fields, extends up to the foot of the Ghats. Here are great forests which form a considerable source of wealth.

In 1921 the population was 979,080, and 185 in every thousand are literate. More than a quarter are Christians, mostly Syrians and Roman Catholics. The tribute is £13,333, and the financial condition of the state is flourishing. The principal products are rice, coconuts and timber. Cochin is the centre of the coconut oil trade and coconut products are the chief export. Salt is manufactured along the coast. The capital is Ernakulam, but the maharaja resides at Tripunthura. The principal commercial centre is Mattancheri, adjoining the British town of Cochin. The chief

means of communication is by boat along the backwaters; but the line of the Cochin State railway connects Ernakulam with Shoranur, and a tramway for work in the forests runs to Chalakudi, a distance of 52 miles.

History.—What is now the native State of Cochin was, until about the middle of the 9th century A.D., part of the Chera or Kerala kingdom (*see* KERALA). Its port of Kodungalur was from early times one of the chief centres for the trade between Europe and India. The history of Cochin is exceedingly obscure previous to the arrival of the Portuguese. The rajas of Cochin, who are of pure Kshatriya blood, claim descent from the Chera king Cherman Perumal. About the middle of the 9th century this king, according to tradition, resigned his kingdom, embraced Islam, and went on pilgrimage to Arabia, where he died. Towards the end of the century the Chera kingdom was overrun and dismembered by the Cholas. In 1498 Vasco da Gama reached the Malabar coast; and in 1502 the Portuguese were allowed to settle in the town of Cochin, where they built a fort. By the end of the century their influence had become firmly established, largely owing to the effective aid they had given to the rajas of Cochin in their wars with the Zamorin of Calicut. In 1663, however, the Dutch captured Cochin and held it for about 100 years. In 1776 Hyder Ali of Mysore invaded the State and forced the raja to acknowledge his suzerainty and pay tribute. In 1791 Tippoo, son of Hyder Ali, ceded the sovereignty to the British, who entered into a treaty with the raja, by which he became their vassal and paid an annual tribute of a lakh of rupees. On October 17, 1809, in consequence of an attempt of the hereditary chief minister, Paliyath Achan, in 1808, to raise an insurrection against the British without his master's knowledge, a fresh treaty was made by which the raja undertook to hold no correspondence with any foreign State and to admit no foreigners to his service, without the sanction of the British Government.

From this time the State greatly advanced in prosperity under successive rajas. For over 100 years trade was developed until the annual revenue reached 70 lakhs of rupees. In 1923 Cochin with Travancore, Pudukkottai and two smaller States were placed in direct relation with the Government of India as the Madras States.

COCHIN, a town in British India, in the district of Malabar, Madras. Pop. (1921) 20,637. The town lies at the northern extremity of a strip of land about 12 m. in length, but in few places more than a mile in breadth, which is nearly isolated by inlets of the sea and estuaries of streams flowing from the Western Ghats. These form the Cochin backwaters, shallow lagoons lying behind the beach-line and below its level, which are broad navigable channels and lakes during the monsoon, but in many places not 2 ft. deep in the hot weather. The first European possessors of Cochin were the Portuguese. Vasco da Gama founded a factory in 1502, and Albuquerque built a fort, the first European fort in India, in 1503. The British made a settlement in 1634, but retired when the Dutch captured the town in 1663. Under the Dutch the town became a great trading centre. In 1795 Cochin was captured from the Dutch by the British, and in 1806 the fortifications and many buildings were blown up by order of the authorities. Cochin is the third port between Bombay and Colombo, and considerable sea-borne trade is carried on, although steamers have to lie 2½ m. out at sea, and the harbour is practically closed from May to August. An experimental channel was cut through the bar in 1923 in pursuance of a scheme for improving the harbour and reclaiming land for port buildings, in which the British government is collaborating with those of Cochin and Travancore. A dry dock, wharves, etc., have recently been built, and work was in progress in 1927. The railway terminus is at Ernakulam, 2½ m. from Cochin. There are brick and coir works, saw and oil mills; and fishing, boat-building and mat-making are carried on. The chief exports are coco-nut products, tea and groundnuts.

COCHIN-CHINA, the six southern provinces of the empire of Annam annexed by France (1862-67), bounded west by the Gulf of Siam, north-west and north by Cambodia, east by Annam and south-east by the China Sea; the land frontiers are mostly

artificial; the area is 22,000 sq. miles. The population (1926) was 3,864,496; mostly Annamese, but including some 200,000 Cambodians or Khmer.

It is mainly alluvial plain, the delta of Mekong and Don-Nai, area about 17,200 sq. miles. The soil is mainly river alluvium, which in the quaternary period has covered and filled in the gulfs of the archæan and palæozoic continental massif (granites, schists, etc.). Volcanic rocks are rare save for the basalts of Bien-Hoa (north of Saigon) and trachytes south-west of the delta. But laterites of volcanic origin, red earths easy to cultivate, are common, as are argillo-silicious grey earths.

The arc of the Annamese Cordillera ends at Cap St. Jacques and extends over the provinces of Tay-Ninh, Bien-Hoa and Baria, without anywhere reaching a height of 2,900 feet. The 180 m. of low marshy coast from Cap St. Jacques to Cap de la Table has some open bays and the projection of the point of Ca-Mau. The only port is Saigon, 31 m. from the sea. Waterways are abundant, and from June to October floods of the Mekong (*q.v.*) cover the country, save for dykes and villages and the Plaine des Jones in

BY COURTESY OF FRENCH TOURIST BUREAU
FISH MERCHANTS IN COCHIN-CHINA

the north, and part of the Ca-Mau peninsula. Rivers include the Don-Nai, flowing west and then south from the Annamese mountains to the sea, west of Cap St. Jacques, the Saigon, flowing north-west to south-east and joining the Don-Nai, and the two Vaicos, joining the Don-Nai near its mouth. The deltas of all these rivers are joined to that of the Mekong and to the sea by many canals (Arroyos), both natural and artificial. To them the country owes its scheme of communications and the general distribution of fertilizing floodwaters, and the port of Saigon (*q.v.*) has become the export centre for Cochin-China, Cambodia and Laos. Canals from Chau-Doc to Ha-Tien, and from Long-Xuyen to Rach-Gia join the Mekong to the gulf of Siam.

The climate depends upon the monsoon, the south-west monsoon, blowing from May to October, brings at times as much as 6.35 metres of rain (2.35 metres at Soc Trang). The dry north-east monsoon blows from November to April. There are no typhoons. The temperature averages 79° in January, 84.4° in April and 81.5° for the year. The rich forests shelter tiger, leopard, tiger cat, ichneumon, wild boar, deer, buffalo, rhinoceros and elephant, as well as many species of monkeys and rats. Some species of parakeet, the Mandarin blackbird, and the woodcock are found in the rest of Indo-China. Aquatic birds abound in the delta, venomous reptiles abound and the Mekong has crocodiles.

Cultivation.—The cultivation of rice is so widespread that 150,000 tons of seed are used every year, and the harvest averages 1,200 kg. per hectare (say, 1,072 lb. per acre); the principal industrial establishments are those which deal with rice at Saigon and Cholon. Cultivation of Hevea rubber is spreading on the "red earths," and a silk farm has been founded at Tan-Chan. The coco-nut palm is found everywhere and serves many purposes. Pepper is grown in the districts of Ha-Tien and Bien-Hoa; sugar cane, coffee, cotton, tobacco, etc., are also produced. The buffalo (*Bos Bubalus*) is very generally used in the work of rice cultivation. The rice preparing establishments are run by Chinese; other activities include silk-weaving, sugar-making, extraction of lime, extraction of salt from sea water, fishing and the preparation of Nuoc-Mam (fish sauce).

Of exports, rice is the chief, followed by fish (dry or salted), pepper, copra, sesamum, castor oil, earth-nuts and cotton. Imports include textiles, machinery, wines, tea, etc. The largest ves-

sels can reach the ports of Saigon and My-Tho, and they are linked by rail. The roadsteads of Rach-Gia, Ca-Mau and Ha-Tien can accommodate only small vessels.

Government Administration.—A lieutenant-governor administers Cochinchina under the governor-general of Indo-China. He has a *conseil colonial* of 16 members, six of whom are French citizens elected by the French, six natives elected by the natives, the other four being members of the chamber of commerce of Saigon and the *conseil privé*. The *conseil colonial*, besides its advisory functions, discusses and votes the budget, determines the taxes, controls tariffs, and administers colonial domains. The *conseil privé* is a deliberative body under the presidency of the lieutenant-governor, composed of colonial officials, together with two native members. Decrees of Feb. 1926 offer natives, with equal qualifications, free access to all ports in the French administration. The colony is divided into four circumscriptions (Saigon, My-Tho, Vinh-Long, Bassac), at the head of each of which is an inspector of native affairs. These are subdivided into 20 provinces, each under an administrator of native affairs, by whose side is the native provincial council, and occupied with discussion of ways and means and of public works. The provinces are divided into cantons, subdivided into communes. The commune forms the basis of the native social system. Its assembly of notables or municipal council forms a sort of oligarchy, the members of which themselves elect individuals from among the more prominent inhabitants to fill vacancies. The notables elect the provincial councillors in the proportion, usually, of one to every canton, and their delegates elect the chief of the canton, who voices the wishes of the natives to the Government. Local administration, e.g., supervision of markets, policing, land-transfer, etc., are carried on by a mayor and two assistants, to whom the municipal council delegates its powers. The same body draws up the list of males liable to poll-tax and of lands liable to land-tax, the chief sources of revenue. There are French tribunals of first instance in nine chief towns of the colony, and four of these have criminal courts. These administer justice in accordance both with French law and, in the case of natives, with Annamese law, which has been codified for the purpose. Saigon has two chambers of the court of appeal of French Indo-China and a tribunal of commerce. Primary instruction is given in some 600 schools. Cochinchina is represented in the French chamber by a deputy. The capital is Saigon (*q.v.*); of the other towns, Cholon (*q.v.*), My-Tho, Vinh-Long and Chau-Doc are important.

In 1927 tax receipts were 11,371,080 piastres, or about 2.92 piastres per head of the population.

History.—The Khmer kingdom (*see* CAMBODIA), at its zenith from the 9th to the 12th centuries, included a large part of Cochinchina, the coastal portion and, perhaps, the eastern region being under the empire of Champa, which broke up during the 15th century. This eastern region was occupied in the 17th century by the Annamese, who in the 18th century absorbed the western provinces. From this period the history of Cochinchina follows that of Annam (*q.v.*) till 1867, when it was entirely occupied by the French and became a French colony. In 1887 it was united with Cambodia, Annam and Tongking to form the Indo-Chinese Union. (*See* INDO-CHINA, FRENCH.)

COCHINEAL, a natural dye-stuff used for the production of scarlet, crimson, orange and other tints, and for the preparation of lake and carmine. It consists of the females of *Dactylopius coccus*, an insect of the family *Coccidae* of the order Hemiptera, which feeds upon various species of *Cactaceae*, especially nopal, *Opuntia coccinellifera*, a native of Mexico and Peru. The dye was introduced into Europe from Mexico, where it had been used long before the entrance of the Spaniards. Cochineal has almost entirely been replaced by aniline dyes. The male of the cochineal insect is half the size of the female, and, unlike it, is devoid of nutritive apparatus; it has long white wings, and a body of a deep red colour, terminated by two diverging setae. The female is wingless, and has a dark-brown plano-convex body; it is found in the proportion of 150–200 to one of the male insect. The dead body of the mother insect serves as a protection for the eggs until they are hatched. Cochineal is now furnished

not only by Mexico and Peru, but also by Algiers and southern Spain. It is collected thrice in the seven months of the season. The insects are carefully brushed from the branches of the cactus into bags, and are then killed by immersion in hot water, or by exposure to the sun, steam, or the heat of an oven—much of the variety of appearance in the commercial article being caused by the mode of treatment. The dried insect has the form of irregular, fluted and concave grains, of which about 70,000 go to a pound. The best crop is the first of the season, which consists of the unimpregnated females; the later crops include an admixture of young insects and skins, which contain proportionally little colouring matter.

Cochineal owes its tinctorial power to the presence of a substance termed cochinealin or carminic acid, $C_{22}H_{20}O_{13}$ (the formula shown by Dimeoth in 1920), which may be prepared from the aqueous decoction of cochineal. Cochineal also contains a fat and wax; cochineal wax or coccerin, $C_{30}H_{60}(C_{31}H_{61}O_2)_2$, may be extracted by using benzene; the fat is a glyceryl myristate $C_3H_5(C_{14}H_{27}O_2)_3$.

COCHLÄUS (Dobneck), **JOHANN** (1479–1552), German humanist and controversialist, was born at Wendelstein (near Nuremberg), whence the punning surname Cochläus (spiral). In 1507 he graduated at Cologne and published under the name of Wendelstein his first piece, *In musicam exhortatorium*. He then became a schoolmaster at Nuremberg. In 1515 he was at Bologna, hearing (with disgust) Eck's famous disputation against usury, and associating with Ulrich von Hutten and humanists. He took his doctor's degree at Ferrara (1517), and spent some time in Rome, where he was ordained priest. In 1520 he became dean of the Liebfrauenkirche at Frankfurt, where he first entered the lists as a controversialist against the party of Luther, developing that bitter hatred to the Reformation which animated his forceful but shallow ascription of the movement to the meanest motives, due to a quarrel between the Dominicans and Augustinians. Luther would not meet him in discussion at Mainz in 1521. He was present at the diets of Worms, Regensburg, Speyer and Augsburg. The peasants' war drove him from Frankfurt; he obtained (1526) a canonry at Mainz; in 1529 he became secretary to Duke George of Saxony, at Dresden and Meissen. The death of his patron (1539) compelled him to take flight. He became canon (Sept. 1539) at Breslau, where he died on Jan. 10, 1552.

His best known work is *Commentaria de Actis et scriptis Lutheris* (1549; German ed. 1580 and 1582). His *Kleine Schriften* were edited by J. Schweizer (1920). *See* M. Spahn, *Johannes Cochläus* (1898).

COCKADE, a knot of ribbons or a rosette worn as a badge, particularly in modern usage as part of the livery of servants. The cockade was at first the button and loop or clasp which "cocked" up the side of an ordinary slouch hat. The word first appears in this sense in Rabelais in the phrase "*bonnet à la coquarde*," explained by Cotgrave (1611) as a "Spanish cap or fashion of bonnet used by substantial men of yore . . . worn proudly or peartly on th' one side." The bunch of ribbons as a party badge developed from this button and loop. The Stuarts' badge was a white rose, and the resulting white cockade figured in Jacobite songs. William III.'s cockade was of yellow, and the house of Hanover introduced theirs of black, which in its present spiked or circular form of leather is worn by the royal coachmen and grooms, and the servants of all officials or members of the services. At the outbreak of the French Revolution of 1789, cockades of green ribbon were adopted. These afterwards gave place to the tricolour cockade, which is said to have been a mixture of the traditional colours of Paris (red and blue) with the white of the Bourbons, the early Revolutionists being still Royalists. The French army wore the tricolour cockade until the Restoration. Each foreign nation had its cockade. Thus the Austrian was black and yellow, Bavarian light blue and white, Belgian black, yellow and red, French the tricolour, Prussian black and white, Russian green and white, and so on, following usually the national colours. Originally the wearing of a cockade, as a badge, was restricted to soldiers. There is still a trace of the cockade as a badge in certain military headgears in England and elsewhere.

Otherwise it has become entirely the mark of domestic service.

See *Genealogical Magazine*, vols. i.-iii. (1897-99); Racinet, *La Costume historique* (1888).

COCKAIGNE (COCKAYNE), **LAND OF**, an imaginary country, a mediaeval Utopia where life was a continual round of luxurious idleness. The origin of the Italian word *cocagna* has been much disputed. It seems safest to connect it, as do Grimm and Littré, ultimately with Lat. *coquere*, through a word meaning "cake," the literal sense thus being "The Land of Cakes." In Cockaigne the rivers were of wine, the houses were built of cake and barley-sugar, the streets were paved with pastry, and the shops supplied goods for nothing. Roast geese and fowls wandered about inviting folks to eat them, and buttered larks fell from the skies like manna. There is a 13th-century French *fabliau*, *Cocaigne*, which was possibly intended to ridicule the fable of the mythical Avalon, "the Island of the Blest." The 13th-century English poem *The Land of Cockayne*, is a satire on monastic life. The term has been humorously applied to London, and by Boileau to the Paris of the rich. The word has been frequently confused with Cockney (*q.v.*).

See D. M. Méon *Fabliaux et contes* (1808), and F. J. Furnivall *Early English Poems* (Berlin, 1862).

COCKATOO (*Cacatuidae*), a group of parrots confined to the Australian region and characterized by a crest of feathers on the head; this can be raised at will. They live in flocks in woods, feeding on fruit, seeds and insects. The note is harsh and their powers of vocal imitation limited. The well-known sulphur-crested cockatoo (*Cacatua galerita*) inhabits Australia, where it does much damage to the newly sown grain. The white eggs, two in number, are deposited in hollow trees or fissures in rocks. Leadbeater's cockatoo (*C. leadbeateri*) inhabits South Australia, and its white plumage is tinged with rose, deepening to salmon-pink under the wings; the crest is scarlet. It is a very shy bird. The dark-plumaged funereal cockatoo or wyla (*Calyptorhynchus funereus*) is another Australian species. The smallest of the family is the cockateel (*Calopsittacus novae-hollandiae*), which has a long pointed tail.

COCKATRICE, a fabulous monster, the existence of which was firmly believed in throughout ancient and mediaeval times. Produced from a cock's egg hatched by a serpent, it was believed to possess the most deadly powers, plants withering at its touch, and men and animals dying, poisoned, by its look. It stood in awe, however, of the cock, the sound of whose crowing killed it. The weasel alone among mammals was unaffected by the glance of its evil eye, and attacked it at all times successfully; for when wounded by the monster's teeth it found a ready remedy in rue—the only plant which the cockatrice could not wither. The term "cockatrice" seems also to be synonymous with "basilisk."

COCKBURN (kô'burn), **SIR ALEXANDER JAMES EDMUND**, 10TH BART. (1802-1880), lord chief justice of England, born Dec. 24, 1802, of ancient Scottish stock, the son of Alexander, fourth son of Sir James Cockburn, 6th baronet. His father was British envoy extraordinary and minister plenipotentiary to the state of Colombia, and married Yolande, daughter of the vicomte de Vignier. He was educated at Trinity Hall, Cambridge, of which he was elected a fellow and afterwards an honorary fellow. He entered at the Middle Temple in 1825 and was called to the bar in 1829. He joined the western circuit, and for some time such practice as he was able to obtain lay at the Devon sessions. In 1832, however, the petitions following the first general election after the Reform Bill gave him an opening. The decisions of the committees had not been reported since 1821, and with M. C. Rowe, another member of the western circuit, Cockburn undertook a new series of reports. In 1833 he had his first parliamentary brief.

In 1847 he decided to stand for parliament and was elected, without a contest, Liberal M.P. for Southampton. His speech in the House of Commons on behalf of the government in the Don Pacifico dispute with Greece commended him to Lord John Russell, who appointed him solicitor-general in 1850 and attorney-general in 1851, a post which he held till the resignation of

the ministry in Feb. 1852. During the short administration of Lord Derby, which followed, Sir Frederic Thesiger was attorney-general and Cockburn was engaged against him in the case of *R. v. Newman*, on the prosecution of Achilli, a criminal information for libel against Cardinal Newman. The jury who tried the case under Lord Campbell found the defence of justification not proved except in one particular. The verdict was set aside and a new trial ordered, but none ever took place. In Dec. 1852, under Lord Aberdeen's ministry, Cockburn became again attorney-general, and so remained until 1856, taking part in many celebrated trials, notably leading for the Crown in the trial of William Palmer, of Rugeley in Staffordshire, for poisoning. In 1854 Cockburn was made recorder of Bristol. In 1856 he became chief justice of the common pleas. He inherited the baronetcy in 1858. In 1859 Lord Campbell became chancellor, and Cockburn became chief justice of the Queen's Bench, continuing as a judge for 24 years and dying in harness. On Saturday, Nov. 20, 1880, he presided over a court for the consideration of Crown cases reserved; he walked home, and on that night he died of *angina pectoris* at his house in Hertford Street.

Sir Alexander Cockburn earned and deserved a high reputation as a judge. He was a man of brilliant cleverness and rapid intuition. He had been a great advocate at the bar, fluent and persuasive rather than learned; before he died he was considered a good lawyer, some assigning unquestioned improvement in this respect to his frequent association on the bench with Blackburn. He had notoriously little sympathy with the Judicature Acts. Many were of opinion that he was inclined to make up his mind prematurely on the cases before him. But he was beyond doubt always in intention, and generally in fact, scrupulously fair. It was thought that he went out of his way to arrange to try *causes célèbres* himself. His successor, Lord Coleridge, writing in 1881 to Lord Bramwell, to make the offer that he should try the murderer Lefroy as a last judicial act before retiring, added, "Poor dear Cockburn would hardly have given you such a chance." But Cockburn tried all cases which came before him, whether great or small, with the same thoroughness, courtesy, and dignity, while he certainly gave great attention to the elaboration of his judgments and charges to juries. His summing up at the Tichborne trial at Bar lasted 18 days.

The greatest public occasion on which Sir Alexander Cockburn acted, outside his usual judicial functions, was that of the "Alabama" arbitration, held at Geneva in 1872, in which he represented the British Government and dissented from the view taken by the majority of the arbitrators, without being able to convince them. He prepared, with C. F. Adams, the representative of the United States, the English translation of the award of the arbitrators and published his reasons for dissenting in a vigorously worded document which did not meet with universal commendation. He admitted in substance the liability of England for the acts of the "Alabama," but not on the grounds on which the decision of the majority was based, and he held England not liable in respect of the "Florida" and the "Shenandoah."

In personal appearance Sir Alexander Cockburn was of small stature, but great dignity of deportment. He was fond of yachting and sport, and at the time of his death was engaged in writing a series of articles on the "History of the Chase in the 19th Century." He had a high sense of the duties of his profession, and his utterance upon the limitations of advocacy, in his speech at the banquet given in the Middle Temple Hall to M. Berryer, the celebrated French advocate, may be called the classical authority on the subject. Lord Brougham had spoken of "the first great duty of an advocate to reckon everything subordinate to the interests of his client." But the lord chief justice, replying to the toast of "the judges of England," said amid loud cheers from a distinguished assembly of lawyers, "The arms which an advocate wields he ought to use as a warrior, not as an assassin. He ought to uphold the interests of his clients *per fas*, not *per nefas*. He ought to know how to reconcile the interests of his clients with the eternal interests of truth and justice" (*The Times*, Nov. 9, 1864). Sir Alexander Cockburn was never married, and the baronetcy became extinct at his death.

COCKBURN, ALICIA or ALISON (1713-1794), Scottish poet, author of one of the most exquisite of Scottish ballads, the "Flowers of the Forest," was the daughter of Robert Rutherford of Fairnalee, Selkirkshire, and was born on Oct. 8, 1713, and died on Nov. 22, 1794. There are two versions of this song—the one by Mrs. Cockburn, the other by Jean Elliot (1727-1805) of Minto. Both were founded on the remains of an ancient Border ballad. Mrs. Cockburn's—that beginning "I've seen the smiling of Fortune beguiling"—is said to have been written before her marriage to Patrick Cockburn of Ormiston in 1731, though not published till 1765. It was composed many years before Jean Elliot's sister verses, written in 1756, beginning, "I've heard them liltin' at our ewe-milkin'." At her house on Castle-hill, and afterwards in Crichton street, Mrs. Cockburn received Mackenzie, Robertson, Hume, Home, Monboddo, the Keiths of Ravelston, the Balcarras family, Lady Anne Barnard, the author of "Auld Robin Gray," and others. As a Rutherford she was a connection of Sir Walter Scott's mother, and was her intimate friend. Scott, at six years old, is said to have given as a reason for his liking for Mrs. Cockburn that she was a "virtuoso like himself."

See her *Letters and Memorials* . . . with notes by T. Craig Brown (1900).

COCKBURN, SIR GEORGE, BART. (1772-1853), British admiral, second son of Sir James Cockburn, Bart., and uncle of Lord Chief Justice Cockburn, entered the navy in his ninth year. After serving on the home station, and in the East Indies and the Mediterranean, he assisted, as captain of the "Minerve" at the blockade of Leghorn in 1796, and fought a gallant action with the Spanish frigate "Sabina," which he took. He was present at the battle of Cape St. Vincent. In 1809, in command of the naval force on shore, he contributed greatly to the reduction of Martinique, and signed the capitulation by which that island was handed over to Great Britain. After service in the Scheldt and at the defence of Cadiz he was sent in 1811 on an unsuccessful mission for the reconciliation of Spain and her American colonies. In 1813-14, as second in command to Warren, he took part in the American War, especially in the capture of Washington. In the autumn of 1815 he carried out, in the "Northumberland," the sentence of deportation to St. Helena which had been passed upon Bonaparte. He was promoted admiral in 1837; he became senior naval lord in 1841, and held office in that capacity till 1846. In 1851 he was made admiral of the fleet. He died on Aug. 19, 1853.

COCKBURN, HENRY THOMAS (1779-1854), Scottish judge, with the style of Lord Cockburn, was born in Edinburgh on Oct. 26, 1779. His father was a baron of the Scottish court of exchequer. He was educated at the high school and the University of Edinburgh, and he was a member of the Speculative Society, to which Sir Walter Scott, Brougham and Jeffrey belonged. He entered the faculty of advocates in 1800, and attached himself, though his connections were Tory, to the Whig or Liberal party, which then offered few prospects to ambitious men. On the accession of Earl Grey's ministry in 1830 he became solicitor-general for Scotland. In 1834 he was raised to the bench, and on taking his seat as a judge in the court of session he adopted the title of Lord Cockburn. Cockburn's forensic style was remarkable for its clearness, pathos and simplicity; and his conversational powers were unrivalled among his contemporaries. In 1852 he published his biography of Lord Jeffrey, and the *Memorials of his Time* appeared posthumously in 1856 (new ed., with introduction by his grandson, H. A. Cockburn, 1909). He died on April 26, 1854, at his mansion of Bonaly, near Edinburgh.

COCKCHAFER (*Melolontha vulgaris*), a common European beetle whose larva is destructive to the roots of crops. The white

grub spends several years in the soil before emerging as a large beetle which feeds on the leaves of trees, and may often be seen flying in large numbers at dusk. (See COLEOPTERA; CHAFER; and PESTS.)

COCKERELL, CHARLES ROBERT (1788-1863), British architect, was born in London on April 28 1788. After studying under his father, Samuel Pepys Cockerell (1754-1827), he went abroad in 1810 and studied the great architectural remains of Greece, Italy and Asia Minor. At Aegina, Phigaleia and other places of interest, he conducted excavations on a large scale, enriching the British Museum with many fine fragments. He became R.A. in 1829, and from 1840 to 1857 was professor of architecture at the Academy. In 1837 he was appointed architect to the Bank of England. Among his principal works are the Taylorian Building, Oxford (1842), and the completion of St. George's Hall, Liverpool, and of the Fitzwilliam Museum, Cambridge, with some important bank buildings. Cockerell's best conceptions were inspired by classic models; examples of his Gothic style are the college at Lampeter and the chapel at Harrow. His son, Frederick Pepys Cockerell (1833-78) was also a distinguished architect.

COCKERILL, WILLIAM (1759-1832), English inventor and machinist, was born in England in 1759. He went to Belgium as a simple mechanic, and in 1799 constructed at Verviers the first wool-carding and wool-spinning machines on the continent. In 1807 he established a large machine workshop at Liège. Orders soon poured in on him from all over Europe, and he amassed a large fortune. In 1810 he was granted the rights of naturalization by Napoleon I., and in 1812 handed over the management of his business to his youngest son, John Cockerill (1790-1840), who largely extended his father's business. King William I. of the Netherlands secured him a site at Seraing, where he built large works, including an iron-foundry and blast furnace. The construction of the Belgian railways in 1834 gave a great impetus to these works, branches of which had already been opened in France, Germany and Poland. John Cockerill had practically concluded negotiations to construct the Russian government railways, when his constitution, undermined by overwork, broke down. He died at Warsaw on June 19, 1840. The iron works, among the largest in Europe, are still carried on under the name of La Société Cockerill at Seraing.

COCKERMOUTH, a small town of Cumberland, England, 32 m. S.W. of Carlisle, by the L.M.S.R. Pop. of urban district (1931) 4,789. It is situated at the confluence of the Derwent and Cocker at a focus of ways among the lower western hills of the Lake District. Settlement in the neighbourhood goes back at least to Roman times, there being a small fort a mile west of the town at Papcastle.

Cockermouth (*Cokermuth*, *Cokermue*) was the head of the barony of Allerdale, created and granted to Waltheof in the 12th century. Waltheof probably built the castle, under the shelter of which the town grew up. There are remains of Norman work in the keep, but the castle is in part modernized as a residence. The town received no royal charter, but the earliest records mention it as a borough. In 1295 it returned two members to parliament and then not again until 1640. In 1867 it had one member, and in 1885 it was disfranchised. In 1221 William de Fortibus, earl of Albemarle, was granted a market. The Michaelmas fair existed in 1343, and in 1374 we hear of two horse-fairs, on Whit Monday and at Michaelmas. In 1638 a fair every Wednesday from the first week in May till Michaelmas was granted. The grammar school was founded in 1676. The county industrial school is established in the town. The chief sources of revenue in Norman times were the fisheries and numerous mills. The present industries include coal mining, metal working and transport work, and there is an agricultural trade.

COCK-FIGHTING or **COCKING**, the sport of pitting game-cocks to fight, and breeding and training them for the purpose. The game-fowl is now probably the nearest to the Indian red jungle-fowl (*Gallus gallus*), from which all domestic fowls are believed to be descended. The sport was popular in ancient times in India, China, Persia, and other eastern countries, and was

introduced into Greece in the time of Themistocles. The latter, while moving with his army against the Persians, observed two cocks fighting desperately, and, stopping his troops, inspired them by calling their attention to the valour and obstinacy of the feathered warriors. In honour of the ensuing victory of the Greeks cock-fights were thenceforth held annually at Athens, at first in a patriotic and religious spirit, but afterwards purely for the love of the sport. On the chair of the high priest of Dionysus, in the Theatre at Athens, there is carved a beautiful figure of a winged Eros holding a game-cock just about to fight. Lucian makes Solon speak of quail-fighting and cocking, but he is evidently referring to a time later than that of Themistocles. From Athens the sport spread throughout Greece, Asia Minor, and Sicily, the best cocks being bred in Alexandria, Delos, Rhodes, and Tanagra. For a long time the Romans affected to despise this "Greek diversion," but ended by adopting it so enthusiastically that Columella (1st century A.D.) complained that its devotees often spent their whole patrimony in betting at the pit-side. The cocks were provided with iron spurs (*tela*), as in the East, and were often dosed with stimulants to make them fight more savagely.

From Rome cocking spread northwards, and, although opposed by the Christian church, nevertheless became popular in Great Britain, the Low Countries, Italy, Germany, Spain, and her colonies. On account of adverse legislation cocking has practically died out everywhere excepting in Spain, countries of Spanish origin and the Orient, where it is still legal and extremely popular. It was probably introduced into England by the Romans before Caesar's time. William Fitz-Stephen first speaks of it in the time of Henry II. as a sport for school-boys on holidays, and particularly on Shrove Tuesday, the masters themselves directing the fights, or mains, from which they derived a material advantage, as the dead birds fell to them. It became very popular throughout England and Wales, as well as in Scotland, where it was introduced in 1681. Occasionally the authorities tried to repress it, especially Cromwell, who put a stop to it for a brief period, but the Restoration re-established it among the national pastimes. Contemporary apologists did not, in the 17th century, consider it cruelty at all, but concerned themselves solely with its justification as a source of pleasure. "If Leviathan took his sport in the waters, how much more may Man take his sport upon the land?" From the time of Henry VIII., who added the famous Royal cock-pit to his palace of Whitehall, cocking was called the "royal diversion," and the Stuarts, particularly James I. and Charles II., were among its most enthusiastic devotees, their example being followed by the gentry down to the 19th century. Gervase Markham in his *Pleasures of Princes* (1614) wrote "Of the Choyce, Ordring, Breeding and Dyeting of the fighting-Cocke for Battell," his quaint directions being of the most explicit nature. When a cock is to be trained for the pit he must be fed "thrice or foure daies only with old Maunchet (fine white bread) and spring water." He is then set to spar with another cock, "putting a payre of hots upon each of their heeles, which Hots are soft, humbasted roubles of Leather, covering their spurs, so that they cannot hurt each other. . . . Let them fight and buffet one another a good space." After exercise the bird must be put into a basket, covered with hay and set near the fire. "Then let him sweate, for the nature of this scowring is to bring away his grease, and to breed breath and strength." If not killed in the fight, "the first thing you doe, you shall search his wounds, and as many as you can find you shall with your mouth sucke the blood out of them, then wash them with warm salt water, . . . give him a roule or two, and so stove him up as hot as you can."

Cocking-mains usually consisted of fights between an agreed number of pairs of birds, the majority of victories deciding the main; but there were two other varieties that aroused the particular ire of moralists. These were the "battle royal," in which a number of birds were "set," i.e., placed in the pit at the same time and allowed to remain until all but one, the victor, were killed or disabled; and the "Welsh main," in which eight pairs were matched, the eight victors being again paired, then four, and finally the last surviving pair. Among London cockpits were

those at Westminster, in Drury Lane, Jewin Street, and Birdcage Walk (depicted by Hogarth). Over the royal pit at Whitehall presided the king's cockmaster. The pits were circular in shape with a matted stage about 20ft. in diameter and surrounded by a barrier to keep the birds from falling off. Upon this barrier the first row of the audience leaned. Hardly a town in the kingdom was without its cockpit, which offered the sporting classes opportunities for betting not as yet sufficiently supplied by horse-racing. With the growth of the latter sport and the increased facilities for reaching the racing centres, cocking gradually declined, especially after parliament passed laws against it, so that gentlemen risked arrest by attending a main.

Among the best-known devotees of the sport was a Colonel Mordaunt, who, about 1780, took a number of the best English game-cocks to India. There he found the sport in high favour with the native rulers and his birds were beaten. Perhaps the most famous main in England took place at Lincoln in 1830 between the birds of Joseph Gilliver, the most celebrated breeder, or "feeder," of his day, and those of the earl of Derby. The conditions called for seven birds a side, and the stakes were 5,000 guineas the main and 1,000 guineas each match. The main was won by Gilliver by five matches to two. His grandson was also a breeder, and the blood of his cocks still runs in the best breeds of Great Britain and America. Another famous breeder was Dr. Bellyse of Audlem, the principal figure in the great mains fought at Chester during race-week at the beginning of the 19th century. His favourite breed was the white pile, and "Cheshire piles" are still much-fancied birds. Others were Irish brown-reds, Lancashire black-reds and Staffordshire duns.

In Wales, as well as some parts of England, cocking-mains took place regularly in churchyards, and in many instances even inside the churches themselves. Sundays, wakes, and church festivals were favourite occasions for them. The habit of holding mains in schools was common from the 12th to about the middle of the 19th century. When cocking was at its height the pupils of many schools were made a special allowance for purchasing fighting-cocks, and parents were expected to contribute to the expenses of the annual main on Shrove Tuesday, this money being called "cockpence." Cock-fighting was prohibited by law in Great Britain in 1849.

Cocking was early introduced into America though it was always frowned upon in New England. Some of the older states, as Massachusetts, forbade it by passing laws against cruelty as early as 1836, and it is now expressly prohibited in Canada and in most states of the Union, or is repressed by general laws for the prevention of cruelty to animals.

Cock-fighting is not recognized as a form of sport by the Latin-American countries in general. In Argentina cock-fighting was once one of the most popular amusements; but it is now being abolished by police measures, although it still persists in several provinces. Paraguay prohibits it by law. But in Cuba cock-fighting continues to be a patronized sport regulated by the government. Cubans have always supported it; and, although it was prohibited for a time, it was reinstated during the Gómez administration, and is now regulated by municipal decrees.

Cocks are fought at an age of from one to two years. "Heeling," or the proper fastening of the spurs, and "cutting-out," trimming the wings at a slope, and cutting the tail down by one-third of its length and shortening the hackle and rump feathers, are arts acquired by experience. The comb is cut down close, so as to offer the least possible mark for the hostile bird's bill. The cock is then provided with either "short heels," spurs 1½ in. or less in length, or with "long heels," from 2 to 2½ in. in length. The training of a cock for the pit lasts from ten days to a month or more, during which time the bird is subjected to a rigid diet and exercise in running and sparring. The birds may not be touched after being set down in the pit, unless to extricate them from the matting. Whenever a bird refuses to fight longer he is set breast to breast with his adversary in the middle of the pit, and if he then still refuses to fight he is regarded as defeated. Among the favourite breeds may be mentioned the "Irish gilders," "Irish Grays," "Shawlnecks," "Gordons," "Eslin Red-Quills,"

"Baltimore Topknots," "Dominiques," "War-horses," and "Clairbornes."

BIBLIOGRAPHY.—Cock-fighting possesses an extensive literature of its own. See Gervase Markham, *Pleasures of Princes* (1614); Blain, *Rural Sports* (1853); "Game Cocks and Cock-Fighting," *Outing*, vol. xxxix.; "A Modest Commendation of Cock-Fighting," *Blackwood's Magazine*, vol. xxii.; "Cock-Fighting in Schools," *Chambers' Magazine*, vol. lxxv.

COCK LANE GHOST, a supposed apparition, the vagaries of which attracted extraordinary public attention in London during 1762. At a house in Cock Lane, Smithfield, tenanted by one Parsons, knockings and other noises were said to occur at night varied by the appearance of a luminous figure, alleged to be the ghost of a Mrs. Kent who had died in the house some two years before. A thorough investigation revealed that Parsons' daughter, a child of eleven, was the source of the disturbance. The object of the Parsons family seems to have been to accuse the husband of the deceased woman of murdering her, with a view to blackmail. Parsons was prosecuted and condemned to the pillory.

See A. Lang, *Cock Lane and Common Sense* (1894).

COCKLE, SIR JAMES (1819-1895), English lawyer, and mathematician, was born on Jan. 14, 1819. He was the second son of James Cockle, a surgeon, of Great Oakley, Essex. Educated at Charterhouse and Trinity College, Cambridge, he entered the Middle Temple in 1838, practising as a special pleader in 1845 and being called in 1846. He joined the western circuit and was appointed chief justice of Queensland in 1863. He was knighted in 1869, retired from the bench, and returned to England in 1879.

Cockle is more remembered for his mathematical and scientific investigations than as a lawyer. He attacked the problem of resolving the higher algebraic equations, notwithstanding Abel's proof that a solution by radicals was impossible. In this field Cockle achieved some notable results, amongst which is his reproduction of Sir William R. Hamilton's modification of Abel's theorem. Algebraic forms were a favourite object of his studies, and he discovered and developed the theory of criticoids, or differential invariants; he also made contributions to the theory of differential equations. He was a member of many scientific societies in Queensland and England. He died in London on Jan. 27, 1895.

A volume containing his scientific and mathematical researches made during the years 1864-77 was presented to the British Museum in 1897 by his widow. See the obituary notice by the Rev. R. Harley in *Proc. Roy. Soc.* vol. 59.

COCKLE, a bivalved marine mollusc of the genus *Cardium*, allied to the oyster and placed in the class Lamellibranchia. About 200 living species of cockles are known and over 330 fossil forms have been described. The common or edible cockle (*Cardium edule*) is the best-known example and is of some economic importance.

The two valves of the shell of the cockle are similar and are characterized by a prominent umbo (see LAMELLIBRANCHIA) from which a number of prominent ribs radiate over the surface of the shell. The animal has a long and pointed foot with a knee-like bend in it. The mantle is produced into two short "siphons" which bear numerous finger-like processes. In certain species these processes carry eyes at their tips. The cockle is placed in the order Eulamellibranchiata.

The cockles live on the sea-bottom and are usually found buried below the surface. The common cockle, and probably most of the other species, rarely penetrates below one inch from the surface. The muscular, pointed foot enables it to dig into and plough its way through sand and mud. It has a moderately wide range of habitat, but is rarely found on any soil other than sand and mud. Wright states that *Cardium edule* thrives best in estuarine waters, where the salinity is a little less than that of normal sea-water. Cockle beds formed on the open coast are rarely permanent. In water of high or very low salinity the shell is subject to certain peculiar modifications (Bateson: George). The cockle, like the rest of the Lamellibranchia, has no organs of mastication. It feeds on minute animals and plants and on the organic particles found in sea-water. The spores of Algae, Foraminifera, Diatoms, etc.

usually constitute its diet. The animal is a "current feeder," the food being drawn into the branchial chamber in the water-currents produced by the lower siphon. In England and Wales the most important cockle-fisheries are in the Thames estuary, the Wash, Carmarthen and Morecambe Bays. The animals are gathered by hand or by various kinds of rakes and scrapers and are boiled (in certain places by special methods to ensure the destruction of typhoid bacilli) before being despatched to market. In 1925, 300,221 cwt. of cockles were landed in England and Wales. The nutritional value of the common cockle is fairly high, though its tissues contain less protein and fat than those of the oyster and mussel.

See E. Römer, "Cardium" in *Küster's Conchylien Cabinet* (vol. K, 1869); J. Johnstone, *Cardium* (*Liverpool Mar. Biol. Committee Memoir*, 1899, bibl.); F. Wright, *Fishery Investigations* (Ministry of Agriculture and Fisheries, ix. 5, 1926, bibl.). (G. C. R.)

COCKLEBUR, the name given in the United States to various species of *Xanthium*, of the family Compositae, called also clotbur and bur-weed, which in agricultural districts are

BY COURTESY OF DR. WM. CROCKER
A DETAILED VIEW OF THE BUR AND
THE TWO ENCLOSED SEEDS, SHOW-
ING THE HOOKED PRICKLES WHICH
CATCH IN THE WOOL OF SHEEP

pernicious weeds. They are coarse, rough and sometimes spiny annual herbs with much-branched stems, 1 ft. to 6 ft. high, and mostly long-stalked, variously lobed leaves. The staminate (male) and pistillate (female) flowers, both small and inconspicuous, are borne on separate plants, the staminate clustered at the ends of branches and the pistillate in the axils of the leaves. The fruit (achene) is enclosed in an oblong bur, about an inch in length, covered with hooked spines and ending in a 1- or 2-toothed beak. The ripe burs readily adhere to the hair of farm animals who widely disseminate the plant. When abundant cockleburs are injurious to crops and exhaustive to the soil, but may be controlled by intensive cultivation and by rigorously cutting back or destroying the plants to prevent fruiting in waste grounds.

COCKNEY, a colloquial name applied to Londoners generally, but more properly confined to those born within the sound of the bells of St. Mary-le-Bow church. The origin of the word has been the subject of many guesses, but the historical examination of the various uses of "cockney," by Sir James Murray (see *Academy*, May 10, 1890, and the *New English Dictionary*, s.v.) shows that the earliest form of the word is *cokenay* or *cokeney*, i.e., the ey or egg, and *coken*, genitive plural of "cock," "cocks' eggs" being the name given to the small and malformed eggs sometimes laid by young hens (cf. Langland, *Piers Plowman*, A., vii. 272). The word then applied to a child overlong nursed by its mother, hence to a simpleton, and Chaucer, *Reeve's Tale*, used it with *daf*, i.e., a fool. The application of the term by country folk to town-bred people, with their ignorance of country ways, is easy. Thus Robert Whittington or Whitinton (*f.* 1520), speaks of the "cokneys" in such "great cytees as London, York, Perusy" (Perugia). It was not till the beginning of the 17th century that "cockney" appears to be confined to the inhabitants of London.

The so-called "cockney" accent was chiefly characterized in the first part of the 19th century by the substitution of a *v* for a *w*, or vice versa. The chief consonantal variation which now exists is perhaps the change of *th* to *f* or *v*, as in "fing" for thing, or "farver" for farther. This and the vowel-sound change from *ou* to *ah*, as in "abaht" for "about," are illustrated in the "coster" songs of the late Albert Chevalier. The most marked change of vowel sound is that of *ei* for *ai*, so that "daily" becomes "dyly." The omission of *h* is not peculiar to cockney.

COCK-OF-THE-ROCK, birds of the genus *Rupicola* (subfamily *Rupicolinae*) of the Cotingas (allied to the Manakins, q.v.), found in the Amazon valley. They are about the size of a pigeon, with orange-coloured plumage, a pronounced crest and orange-red flesh, and build their nests on rock. The males hold elaborate "dancing parties."

COCKPIT, originally an enclosed place in which the sport of cock-fighting (q.v.) was carried on. On the site of an old cock-pit opposite Whitehall in London was a block of buildings, used from the 17th century as offices by the treasury and the privy council, for which the old name survived till the early 19th century. The name was given also to a theatre in London, built early in the 17th century on the site of Drury Lane theatre. Applied formerly to a cabin on the lower deck of a man-of-war, where the wounded were tended.

COCKROACH¹, the name applied to members of the *Blattidae*, a family of orthopterous insects, with flattened bodies, long thread-like antennae and shining leathery integument. They are eminently tropical but certain species have become widely disseminated through commerce and are now cosmopolitan. Cockroaches are nocturnal in habit, hiding themselves during the day. The domestic species are omnivorous but are especially addicted to starchy or sweetened matter of various kinds: they also attack provisions, paper, clothing, books, shoes, bones, etc., and dead insects. As a rule they injure and soil far more than they consume, and most species emit a disagreeable odour.

The common or oriental cockroach (*Blatta orientalis*) has the wings shortened in the male and vestigial in the female. The eggs, 16 in number, are laid in a horny capsule or ootheca which is carried for some time, projecting from the body of the female, until it is deposited in some crevice. The capsule ultimately splits and the young insects emerge. They are said to undergo six moults and require at least a year before becoming mature, but little is definitely known on this point. The American cockroach (*Periplaneta americana*) is a much larger insect with fully developed wings in both sexes and in Britain it is found in warehouses and hothouses, etc. It is sometimes found in conjunction with the smaller or so-called German cockroach (*Blattella germanica*). These three species are also widely distributed in North America along with other introduced kinds. About 1,200 species of cockroaches are known and of these only two small species, belonging to the genus *Ectobius*, are true natives of Britain and live out of doors. Although cockroaches are usually sombrely coloured some tropical species exhibit elegance of form and beauty of coloration. The delicate green *Panchlora* sometimes occur in various parts of Britain, being accidentally imported with fruit, etc.

Cockroaches can be readily destroyed by means of special traps baited with molasses; dusting the places they frequent with either sodium fluoride or powdered borax is also effective. Although these insects are usually viewed with disgust they are not devoid of interest. They rank as the most primitive of all winged insects and are among the oldest of all the fossil forms of those animals. Their generalized structure and large size render them convenient objects for laboratory dissection and they are universally adopted as the most suitable type for commencing the scientific study of insects.

See Miall and Denny, *The Structure and Life History of the Cockroach* (1887); Herrick, *Insects injurious to the Household* (1914); Lucas, *British Orthoptera* (1920); Laing, *The Cockroach* (British Mus. 1921).

(A. D. I.)

COCK'S COMB, in botany, a cultivated form of *Celosia cristata* (family *Amarantaceae*), in which the inflorescence is monstrous, forming a flat "fasciated" axis bearing numerous small flowers. The plant is a low-growing herbaceous annual, bearing a large, comb-like, dark red, scarlet or purplish mass of flowers. Other species of *Celosia* cultivated are *C. pyramidalis*, with a pyramidal inflorescence, varying in colour in the great number of varieties, and *C. argentea*, with a dense white inflorescence.

COCKTON, HENRY (1807-1853), English humorous novelist, was born in London Dec. 7 1807, and died at Bury St.

¹The word is a corruption of *Sp. cucaracha*: in America it is commonly abbreviated to "roach."

Edmund's June 26 1853. He is best known as the author of *Valentine Vox, the Ventriloquist* (1840) and *Sylvester Sound, the Somnambulist* (1844).

COCKX (or **COCK**), **HIERONYMUS** (JEROME) (1510-1570), Flemish painter and engraver, was born at Antwerp, and in 1545 was admitted to the Gild of St. Luke as a painter. It is as an engraver, however, that he is famous, a number of portraits and subject-pictures by him, and reproductions of Flemish masters, being well known. His brother Matthys (1505-1552) was also a painter.

COCOA, INDUSTRY AND TRADE. Cocoa is manufactured from the seed of the cacao tree (generally *Theobroma cacao*, rarely *T. pentagona* or *T. sphaerocarpa*, small trees of the family *Sterculiaceae*), a native of tropical America but extensively cultivated elsewhere in the Tropics. The raw product is known commercially as cocoa or the cocoa bean; and scientifically as cacao (*Mex. cacauatl*). The word cocoa is a peculiar English corruption of cacao and will be reserved here solely for the manufactured cocoa powder; whilst cacao will be used for the tree, the "bean," and the butter derived from the bean.

CACAO CULTIVATION

Cacao can be profitably cultivated only within 20 degrees north or south of the equator; it requires a mean shade temperature of 80°F., and an evenly distributed rainfall of 50 to 150 in. a year. The cacao tree requires a rich porous soil of considerable depth, and must be protected from the wind; a secluded vale provides the ideal environment.

Planting.—Growers have preferred in recent times to plant the hardy, well-yielding, *forastero* variety rather than the choicer, but more delicate, *criollo*. Seedlings are grown in nurseries, or the seeds are used straight from the pod. They are planted from 10 to 18 ft. apart, according to the soil, shade, etc. To protect the

FIG. 1.—DIAGRAM OF CHIEF CACAO HARVESTS, SHOWING THE PERIOD OF THE YEAR DURING WHICH THE MAIN CROP OF EACH OF THE PRINCIPAL PRODUCING COUNTRIES IS GATHERED

soil beneath the trees from the glare of the sun either huge shade trees (e.g., the vermilion flowered *Erythrina*) are grown at intervals of 40 to 50 ft., or the cacao trees are planted very closely and hedges are grown to provide wind-breaks.

Harvesting the Crop.—The cacao tree begins to bear in four to five years. The small pink flowers and the succeeding large pods are borne directly on the trunk and main branches.

The chief harvesting periods are shown in the diagram, but ripe pods may be found on the tree all the year round. The pods on the higher branches are cut from the tree by a knife at the end of ?

FIG. 2.—CHART OF AVERAGE MARKET SPOT PRICE OF CACAO, 1913-1927

20ft. pole, and when placed in a heap are individually cut open with a cutlass and the beans scooped out.

Fermenting.—The beans are covered with a sweet glistening snow-white or pale heliotrope pulp, and if left in a heap this sugary pulp begins to ferment. In the more advanced countries, however, it is usual to ferment in boxes. The beans are turned

FIG. 3.—WORLD'S PRODUCTION OF CACAO (BRITISH POSSESSIONS SHADED)

The total production for 1927 of raw cacao beans is estimated at 482,000 metric tons, of which the British Empire supply is some 60%, the Gold Coast being responsible for 208,348 metric tons

from one box to another preferably every day, and their temperature rises to 89°F., 98°F. and 115°F. in one, two and three days respectively, reaching an exceptionally high temperature for yeast fermentation. The criollo variety requires two days' fermentation, and the forastero from five to nine days. The pulp drains away as a fermenting resembling sweet cider. This is allowed to run to waste. A trace of acetic acid produced in the later stages gives the cacao a characteristic pungency resembling vinegar. This is a doubtful advantage, but the total effects of fermentation on colour, flavour and texture increase the value of the bean.

Drying, Washing, Etc.—The bean as it comes from the pod

contains 33% of water. This must be reduced to 5 or 6% to give a satisfactory commercial product. The drying is generally done in the sun on cement or brick floors, on mats of coconut fibre, or on wooden platforms; or, as on the Gold Coast, on light bamboo mats on trestles. Whilst the best results are always obtained by the slow and even drying which is produced by turning over and over in the sun for three days, the climate may necessitate the use of artificial dryers. To a limited extent heated platforms are used in San Thomé, drying rooms in Ceylon and Grenada, and drying machines in Costa Rica, Bahia, etc.

The processes of washing, claying and polishing, peculiar to certain places, have few advantages beyond pleasing the eye of the buyer. In Ceylon and Java the pulp is partly removed by washing and the shell of these beans is fragile and gets broken in handling. In Venezuela a thin coat of red earth is rubbed on to the beans. The similar practice of claying was followed in Trinidad until 1923, when it was prohibited. In some countries polishing machines are used.

Yield.—On an average a full-grown tree may bear 6,000 flowers, of which only 20 will become cacao pods. A pod weighs about 1 lb. and contains 4 oz. of pulp-covered seeds, which yield 1½ oz. of the dry, cured, cacao beans of commerce. From these figures is derived the startling fact that, taking all trees in the world, the average yield of cacao beans to the tree is not more than two pounds per annum, and even on first-class estates rarely exceeds three pounds.

Cacao beans in shape resemble almonds, but are not so pointed; they weigh about 400 to the pound. The skin, or shell, is brown. The inside of a superior kind of bean is the colour of cinnamon; of ordinary kinds, dark brown or purple; and of poor unfermented kinds, slate colour. The taste is more or less bitter and astringent, nutty, and faintly aromatic.

The leading ports for the shipping of cacao are Accra and Secondree (Gold Coast), Bahia and Para (Brazil), Guayaquil (Ecuador), Port of Spain (Trinidad), Lagos (Nigeria), San Thomé (San Thomé) and Sanchez (San Domingo). Whilst some manufacturers have agents at certain producing centres, the great bulk of cacao buying is done through brokers and merchants on cost and freight contracts. The chief cacao markets are New York (where there is a cacao exchange), Hamburg, London,

Where Cacao Is Grown.—The diagram below gives an accurate impression of the relative proportions of the world's supply exported by the chief producing centres in 1926:—

The table below is compiled from a journal published in Hamburg, the *Gordian*, which is the most reliable source of cacao statistics. It shows changes in cacao production between 1906 and 1926:—

World's Harvest of Cacao Beans
(In tons of 1,000 kilos.)

| Producing country. | 1906. | 1916. | 1926. |
|------------------------------|----------------|----------------|----------------|
| Africa | | | |
| Gold Coast | 9,004 | 73,205 | 229,537 |
| Nigeria | 735 | 9,099 | 36,520 |
| San Thomé | 24,477 | 34,336 | 13,581 |
| Cameroons | .. | .. | 8,706 |
| French Ivory Coast | .. | .. | 6,833 |
| America | | | |
| Brazil | 25,135 | 42,879 | 65,806 |
| Trinidad | 12,083 | 24,893 | 22,710 |
| San Domingo | 14,313 | 22,485 | 20,477 |
| Ecuador | 23,427 | 42,667 | 20,036 |
| Venezuela | 12,865 | 15,196 | 14,300 |
| Other countries | 25,000 | 31,227 | 42,905 |
| Total | 147,939 | 295,987 | 481,411 |

The other countries include Costa Rica (5,318), Grenada (4,103), Ceylon (3,372), Jamaica (3,057), Java (904), Belgian Congo, Surinam, Samoa, St. Lucia (494), Dominica (320) and Cuba. The figures in parentheses are for 1926.

The finest type of bean, the criollo, is grown in Venezuela, Ceylon, Java, Samoa, Madagascar and Nicaragua; but in Ceylon, and other places, criollo is being replaced by forastero, and it is doubtful if the world's production of criollo reaches 10% of the whole. During the first quarter of this century cacao production quadrupled, mainly owing to the increased supply from the Gold Coast. The quantity of Nigerian cacao exported from Lagos is rapidly increasing, and the quality, though still poor, is slowly improving. The output of Brazil has also grown and the sum of its Bahia and Para cacaos has established it as the second largest producer in the world. Trinidad cacao is well known for its good quality and

FIG. 4.—THE WORLD'S CONSUMPTION OF CACAO BEANS. IN 1926, THE TOTAL CONSUMPTION WAS 475,241 METRIC TONS

excellent preparation. The Sanchez and Samana cacaos of San Domingo are purchased in New York for the same price as Gold Coast cacao. The Arriba and Machala cacaos of Ecuador are valuable and distinctive, and it is to be regretted that, owing to the outbreak in 1922 of a disease of the cacao tree (appropriately called Witch Broom, *Colletotrichum luxificum*), their output had been reduced to one-half by 1926.

It will be noted that British possessions are responsible for over 60% of the world's supply, and the Gold Coast alone for nearly 50%.

Gold Coast.—The conditions here are unusual, the land being held, and the cacao farms managed, by the native people. It is doubtful if any native-owned industry ever developed with such rapidity as cacao cultivation on the Gold Coast. Figures showing the cacao exported epitomize its history:—

| YEAR. | 1896. | 1906. | 1916. | 1926. |
|-------|-------|-------|--------|---------|
| Tons | 34 | 9,004 | 73,205 | 229,537 |

The cacao grown is the *amelonado* variety of forastero. In the early days the preparation of the cacao was poor, but an ever-increasing amount of sound, fermented cacao has since been produced. Great credit is due to the natives and to the Government for the manner in which difficulties have been overcome.

The presence of the tsetse fly, and hence the absence of pack animals, renders the transport of this immense amount of cacao a difficult problem, which has been solved to a considerable extent by the construction of 495 miles of railways and over 3,000 miles of roads suitable for motor lorries. The difficulty of shipping cacao to ocean liners, which is increased by the presence of a heavy surf, has been countered by the construction of a deep sea harbour at Takoradi. The two dangers which threaten cacao cultivation—the reduction of rainfall by the destruction of the moisture-drawing forests, and the destruction of the cacao trees by disease or pest—are recognized as problems by the department of agriculture and the educated native.

Prices.—Below is a chart showing the variation in price of four different classes of cacao from 1913–27. The chief points of interest are the Government control of prices during 1918, and the phenomenal rise and fall which followed the removal of the control.

The prices given in the chart do not include import duties. The table below shows changes in import duty; since 1919 British empire-grown cacao has had a preferential duty.

Duty on Cacao, Cacao Butter and Cacao Shell
(Imported in Great Britain, 1853–1927.)

| Year. | Raw cacao, per lb. | | Cacao butter, per lb. | | Cacao shell, per cwt. | |
|-----------------------------|--------------------|----------|-----------------------|----------|-----------------------|----------|
| | British. | Foreign. | British. | Foreign. | British. | Foreign. |
| 1853–1915 | d. | d. | d. | d. | s. d. | s. |

| 1924 | 1½ | 1½ | 1½ | 1½ | 1 8 | 2 |

MANUFACTURE AND CONSUMPTION

Cacao beans, if roasted and crushed in the palm of the hand, produce the fragrant odour of chocolate and are broken up into brown, crisp, angular fragments which are termed "nibs." It is a simple matter to blow away the thin flakes of the husk, or shell, without losing the nib. The nib contains 54–55% of cacao butter, and if simply ground with sugar, gives with hot water a very fatty beverage which for over 100 years has been served out to the British navy. To produce a less rich beverage two methods have been adopted. The first is the addition of corn-flour or arrow-root. Such mixtures cannot in most countries legally be described as pure cocoa. The second is the removal of part of the cacao butter by pressure. This is the usual method, and cocoa may be defined as the finely ground cacao nib from which part of the cacao butter has been removed. The factory operations are as follows:—

The clean sorted beans pass along a conveyor to the roasting machines. Roasting is a delicate operation requiring experience and discretion, and is usually conducted in revolving drums heated externally by gas. The temperatures used are lower than for coffee roasting, and seldom exceed 140°C. The roasted beans pass between rolls of serrated cones, which are placed at such a distance apart that the beans are cracked rather than crushed. The fragments are sieved into fractions, from which the shell is carried off by an air blast. There is 12% of shell on the beans and this voluminous by-product was sold during the war at high prices for making "cocoa tea"; its chief use in normal times is as an appetiser in compound cattle cakes, although a certain amount may be found in inferior cocoas. The nibs are ground either between mill stones or steel rolls. As half the cacao bean is butter, and grinding generates heat, the crisp, nutty cacao nib emerges as a thick chocolate-brown fluid. (If cooled this solidifies to a hard block and is known as unsweetened chocolate or cacao "mass.") The cacao fluid is run into circular steel pots, and hydraulic pressure up to 6,000 lb. to the sq.in. is applied. The cacao butter which is squeezed out is filtered and solidified. The hard, dry cake of compressed cocoa, containing 20 to 30% of cacao butter, is removed from the pot, ground and sieved. Many cocoas receive a special treatment in addition to the above, and are known commercially, though somewhat inaccurately, as "soluble." The process, in its original form, was invented by C. J. van Houten in 1828. It consists of treating the cacao nib or mass with a small percentage of potassium carbonate, bicarbonate or other salt of the alkalies. The alkaline salt reacts with the astringent constituents and partly neutralizes the natural acidity of the cacao. This is considered to improve the cocoa, which becomes darker in colour and less liable to sink to the bottom of the cup.

Cocoa has a high food value, and is mildly stimulating owing to the presence of theobromine (2.2%) and caffeine (0.1%). Dr. R. H. A. Plimmer's *Analyses and Energy Values of Foods* (1921) for use by His Majesty's Services gives the following mean analyses of six cocoas: Fat (cacao butter) 26.8%, carbohydrates 40.3%, protein 18.1%, fibre 3.7%, ash 6.3%, water 4.9%; and the energy value as 2,214.5 calories per pound.

Cocoa Consumption.—Whilst the world's appetite for cacao preparations has continually grown, the war was responsible for a special increase. In the United States the increase has also been influenced by the absence of import duty. The chart below illustrates the relative consumption in various countries in 1926, whilst the table shows the changes in consumption between 1906 and 1926:—

World's Consumption of Cacao Beans
(In tons of 1,000 kilos.)

| Consuming country. | 1906. | 1916. | 1926. |
|-----------------------|---------|---------|---------|
| United States . . . | 37,949 | 105,361 | 187,882 |
| Germany | 35,261 | 11,000 | 61,484 |

FIG. 6.—GROUP OF CACAO PODS
One pod is cut open to show the inside closely packed with pulp-covered beans

FIG. 7.—CACAO PODS OF THE
HARDY FORASTERO TYPE

Over 90% of the raw cacao consumed in Great Britain in 1926 was grown in the British empire.

For bibliography, history and production of manufactured products see CHOCOLATE. (A. W. KN.)

COCOA BUTTER, the pure fat extracted by pressure from the ground and crushed cocoa bean. It is used in the manufacture of confectionery, cosmetics and other toilet preparations. Cocoa butter is sold free from combination with other drugs for treating skin irritations where a pure fat is necessary.

COCO DE MER or **DOUBLE COCO-NUT**, a palm, *Lodoicea Seychellarum*, a native of the Seychelles islands. The flowers are borne in enormous fleshy spadices, the male and female on distinct plants. The fruits, among the largest known, take ten years to ripen; they have a fleshy and fibrous envelope surrounding a hard nut-like portion which is generally two-lobed, suggesting a double coco-nut. The contents of the nut are edible. The empty fruits (after germination of the seed) are found floating in the Indian ocean, and were known long before the palm was discovered.

COCOMA or **CUCAMAS**, a tribe of South American Indians living on the Marañon and lower Huallaga rivers, Peru, speaking dialects related to the Tupi-Guarani stock.

COCONUCAN, a linguistic stock or sub-stock of South American Indians, so called from the Coconucos, its best known tribe. The Coconucan tribes lived on the western slopes of the Cordillera Central, east of Popayan in southern Colombia. Although formerly regarded as an independent linguistic stock, Rivet believes the languages of these tribes to be related to the Chibchan (*q.v.*). The Coconucos were a sedentary, agricultural people, warlike in character, and apparently of the same general level of culture as the neighbouring Chibchan tribes. Apart from scanty references in the early chronicles, little is known concerning the group.

See H. Beuchat and P. Rivet, *Affinités des langues du sud de la Colombie et du nord de l'Equateur* (Museum, 1910, vol. xi.).

COCO-NUT OIL AND CAKE. The bulk of the world's supply of copra and coco-nut oil (the older spelling *cocoanut* is obsolete) is derived from the fruit of the variety *Cocos nucifera* of the coco-nut palm, which grows on the coast of all tropical countries, and is extensively cultivated in the Malay Archipelago, India and Ceylon. When fully ripe the nuts contain only a small amount of milk, the bulk having coagulated to form the thick, fleshy endosperm—coco-nut "meat." This "meat" contains about 30 to 40% of oil and 50% of water. The nuts are collected, and each split into three parts (by native labour) with an axe or by striking on an iron spike fixed in the ground. The coir is removed and the broken kernels dried. The resulting dried meats, which shrink away, and are readily detached, from the shells, are termed *copra* ("copperah"). One thousand nuts yield from 440 to 550 lb. copra containing approximately 10% of water. It is found necessary to dry the meats as the large amount of water present in the fresh kernels favours the growth of fungi, leading to rapid putrefaction of the albumenoids present in the endosperm and consequent rancidity of the oil.

Drying Copra.—The earliest method of drying was to expose the kernels to the air and sun, a practice still extensively followed which gives a good quality white copra ("sun-dried" copra). A more rapid primitive process, adopted particularly in districts where the humidity of the air is excessive, is drying by fire ("kiln drying"). The older method was to spread the kernels on a grating of bamboo cane over a slow fire. As this practice exposed the kernels to the smoke from the fire, an inferior quality copra resulted. Further, in these primitive kilns the copra was frequently charred on the outside, causing it to yield a yellowish oil almost impossible to bleach. A more satisfactory method, first introduced in India and Samoa, is to dry by means of hot air. The meats are spread over a lattice of bamboo sticks covered with coco-nut leaves, placed on trays, and drawn slowly through a heated tunnel meeting a counter-current of hot air. This method yields the finest and whitest copra, which fetches a higher price than the sun-dried article, and is sold chiefly for the "desiccated coco-nut" used in confectionery. It is stated that even better

FURTHER STEPS IN THE MANUFACTURE OF COCOA

1. Steel rolls used in the process of milling the cacao nibs into liquor
2. Presses shown for removing part of the cacao butter from the cacao fluid
3. Flour boilers sifting the cocoa powder through silk meshes
4. Packing cocoa for the retail market

results are obtained by the use of rotary driers, recently introduced in the West Indies. The fresh kernel yields about 60% of dried copra. To inhibit the growth of fungi the amount of water in the dry product should not exceed 4%, although a large amount of the copra on the market contains as much as 10%. The proportion of oil in kiln-dried copra varies from 63 to 65%, while in the hot-air dried product it may rise to 74%. The bulk of the copra is used for the subsequent production of coco-nut oil and cake.

The oil of the coco-nut has been used as an article of food from ancient times. The earliest method of obtaining it was to break the raw kernels into small pieces and expose them to the sun in heaps, from which the oil ran out spontaneously. An improved method, practised in India from a very early date, consists in triturating the sun-dried copra in a mortar and then subjecting the mass to pressure in simple primitive presses. By the native method which produces the finest and whitest oil, the fresh kernels are pounded to a pulp and thrown into boiling water. The clear oil as it rises to the surface is skimmed off, the residual pulp, "coco-nut *poonac*" is used as a cattle food. This process, carried out on a large scale at Cochin on the Malabar coast, has survived to the present day, "Cochin" oil still representing the highest quality. This is in part due to the short time the oil remains in contact with putrescible matter. When prepared with the same care, oils equalling the finest Cochin oil can be, and are, produced in other places (e.g., Ceylon).

Hydraulic Pressing.—The coco-nut oil extracted in Europe from imported copra is prepared by comminuting and expressing the mass in hydraulic presses. In India and Ceylon large

BY COURTESY OF ROSE, DOWNS AND THOMPSON, LTD.

FIG. 1.—SKETCH OF HYDRAULIC CAGE-TYPE PRESSES AND KETTLE
The crushed copra, steam-heated in the kettle, passes in the form of meal to the press-box. When the box is full, hydraulic pressure of 3 to 4 tons per sq. in. is applied. The oil thus expressed flows through the opening of the cage to a collecting trough

central hydraulic installations are gradually superseding the primitive native presses.

Preparatory to pressing, the copra is passed over a magnetic separator to remove any pieces of iron (hammer-heads, nails, etc.) and reduced to a meal by passing between fluted revolving chilled-iron crushing rolls. From these it is carried by means of an elevator into the "kettle" which is placed above the presses. In this it is heated to a temperature of about 60°C. and moistened by steam. This treatment ruptures the cell-walls, thus enabling the oil to exude more readily. The kettle delivers the material in quantities sufficient to form one cake at each operation. These cakes ("cooked meats") are then delivered to the presses, which

may be "cage" presses or of the "Anglo-American" type. Copra is so rich in oil that it requires at least two pressings.

The "cage," or "clodding," press consists of a circular box built up of steel staves held in position by steel hoops; the staves almost touch one another, but the oil can flow through the interstices while the meal is retained. The "cooked meats" are separated by flat mats of wool or hair and are compressed by the rising hydraulic ram. As the mats have to bear very little strain, there is a large saving in wear of press cloths in the cage press as compared with the Anglo-American

BY COURTESY OF GREENWOOD & BATTY, LTD.
FIG. 2.—ANGLO-AMERICAN TYPE OF HYDRAULIC OIL-PRESS

In this machine the meal cakes, already measured and wrapped in press-cloths, are placed between the press plates and hydraulic pressure applied. This type of press yields more coherent cakes and is used for the final pressing, but the cage press is to be preferred for the first pressing of a material so rich in oil as copra, since there is less tendency for speuing of the meal. **The Cake.**—The pressure on the meal in the cage press is gradually increased to a maximum of three to four tons to the square inch. When the oil has ceased to flow the cakes are removed and broken up in a special machine termed a "cake-breaker." They are then re-cooked and subjected to similar pressure in the plate press. On removal from this press the edges of the cake, which are richer in oil than the bulk, are trimmed off. The cakes ("coco-nut oil cake") thus formed are sold as a cattle food to the stock-raiser. They contain from 7 to 10% of oil, and although poorer in proteins than linseed cake, are valued by the farmer for dairy cattle, as they are supposed to stimulate milk-production; this assumption has not been fully confirmed. The parings of the cakes are re-pressed to obtain more oil. Mouldy or rancid cakes from low-grade copras unfit for cattle food are extracted with a volatile solvent to recover the oil they contain.

Coco-nut oil, which is liquid in the tropics, is a solid fat in temperate climates, white to yellowish in colour and possessing a characteristic odour of coconut flesh. It is distinguished chemically by its low iodine value (absence of unsaturated fatty acids) and by the presence of considerable quantities of glycerides of the lower saturated fatty acids (myristic and lauric) and also of the volatile capric, and caprylic acids. As it possesses the exceptional property of being saponified by simple mixing with warm concentrated caustic lyes, it forms the principal ingredient of cold-process soaps. It is valued in milled and "washer" soaps (hard soaps made by the boiling process) owing to the free-lathering properties it imparts to them. As coco-nut-oil soap is soluble in brine, it is used in "marine soaps" intended for use at sea. Coco-nut oil is also largely employed in the manufacture of margarine, vegetable butters, lards, etc., and as a substitute for cacao butter in the manufacture of chocolate. For edible purposes the free fatty acids must be removed by means of alkali and the oil deodorized by treatment with superheated steam *in vacuo*. It can be stiffened by expressing some of the more liquid constituents. Coco-nut oil has also been suggested as a fuel for Diesel engines; and its use for batching jute has been patented.

The following figures show the distribution of exports and imports of copra and oil of the principal producing and consuming countries. (Figures from the *Year Book of Agricultural Statistics* 1926-27, International Institute of Agriculture.)

COCO-NUT PALM (*Cocos nucifera*), a beautiful and lofty palm-tree, growing to a height of 60 to 100 ft. with a cylindrical stem which attains a thickness of 2 ft. The tree terminates in a crown of graceful waving pinnate leaves. The leaf, which may attain to 20 ft. in length, consists of a strong mid-rib, whence numerous long acute leaflets spring, giving the whole the appearance of a gigantic feather. The flowers are arranged in branching spikes 5 or 6 ft. long, enclosed in a tough spathe, and the fruits mature in bunches of from 10 to 20. The fruits when mature are oblong, and triangular in cross section, measuring from 12 to 18 in. in length and 6 to 8 in. in diameter. Each consists of a thick external husk or rind of a fibrous structure, within which is the ordinary coco-nut of commerce. The nut has a very hard, woody shell, enclosing the nucleus or kernel, the true seed, within which again is a milky liquid called coco-nut milk. The three well-known marks on the shell correspond to the three original cavities of the ovary but only one cavity, that containing the "milk," remains in the native fruit. One of the marks, that leading to the single cavity, is soft and easily perforated; beneath it lies the embryo. The palm is so widely disseminated throughout tropical countries that it is impossible to distinguish its original habitat. It flourishes on the coast of the East Indies, throughout the tropical islands of the Pacific, and in the West Indies and tropical America. It, however, attains its greatest luxuriance and vigour on the seashore, and it is most at home in the innumerable small islands of the Pacific seas, of the vegetation of which it is eminently characteristic. Its wide distribution, and its existence in even the smallest coral islets of the Pacific, are due to the character of the fruit, which is eminently adapted for distribution by sea. The fibrous husk renders the fruit light and the leathery skin prevents water-logging. The seed will germinate readily on the seashore, the seedling growing out through the soft germ-pore on the upper end of the hard nut. The fruits dropping into the sea from trees growing on any shores would be carried by tides and currents to be cast up and to vegetate on distant coasts.

The coco-nut palm, being the most useful of its entire tribe to the natives of the regions in which it grows, and furnishing many valuable and important commercial products, is the subject of careful cultivation in many countries. On the Malabar and

Coromandel coasts of India the trees grow in vast numbers; and in Ceylon, which is peculiarly well suited for their cultivation, it is estimated that 20 millions of the trees flourish.

The uses to which the various parts of the coco-nut palm are applied in the regions of their growth are almost endless. The nuts supply no inconsiderable proportion of the food of the natives, and the milky juice enclosed within them forms a pleas-

ONE TREE FROM A PLANTATION OF COCO-NUT PALMS, SHOWING GENERAL HABIT OF GROWTH. THE 50 OR 60 NUTS PROBABLY GROWING ON THIS TREE WILL YIELD ABOUT 25 POUNDS OF COPRA, FROM WHICH 1½ GALLONS OF OIL SHOULD BE OBTAINED

ant and refreshing drink. The juice drawn from the unexpanded flower spathes forms "toddy," which may be boiled down to sugar, or it is allowed to ferment and is distilled, when it yields a spirit which, in common with a like product from other sources, is known as "arrack." As in other palms, the young bud cut out of the top of the tree forms an esculent vegetable, "palm cabbage." The trunk yields a timber (known in European commerce as porcupine wood) which is used for building, furniture, firewood, etc.; the leaves are plaited into cajan fans and baskets, and used for thatching the roofs of houses; the shell of the nut is employed as a water-vessel; and the external husk or rind yields the coir fibre, with which are fabricated ropes, cordage, brushes, etc. The coco-nut palm also furnishes very important articles of external commerce, of which the principal is coco-nut oil. It is obtained by pressure or boiling from the kernels, which are first broken up into small pieces and dried in the sun, when they are known as *copra*. It is estimated that 1,000 full-sized nuts will yield upwards of 500 lb. of *copra*, from which 25 gallons of oil should be obtained. The oil is a white solid substance at ordinary temperatures, with a peculiar, rather disagreeable odour, from the volatile fatty acids it contains, and a mild taste. Under pressure it separates into a liquid and a solid portion, the latter, coco-stearin, being extensively used in the manufacture of candles. Coco-nut oil is chiefly used in manufacture of soap and margarine. Coir is also an important article of commerce, being in large demand for the manufacture of coarse brushes, door mats and woven coir-matting for lobbies and passages. (See *MATTING*.) A considerable quantity of fresh nuts is exported, chiefly from the West Indies.

COCOPA, the Yuman tribe nearest the mouth of the Colorado river, similar in customs to the Yuma and Mohave. The population, originally not far from 3,000, has decreased to about 600, mostly on Mexican soil.

COCYTUS (Gr. *kō-kū-tōs*, anglicized *kō-sī'tus*), a tributary of the Acheron, which flows into the Ionian sea about 20 m. N.

of the Gulf of Arta; identified with a tributary of the Acheron or of the Styx, a river in Hades (*cp.* Virgil's *Aeneid*, vi. 132). The etymology suggested is from *κωκβεῖν*, to wail, in allusion to the cries of mourners; this is probably a reduplicated form, akin to *Skt.* *kū*, cry, with intensive *kokuyate*.

COD, the name given to the typical fish of the family *Gadidae* of the order Anacanthini, which includes fishes without spinous fin-rays, with no duct to the air-bladder, and with the pelvic fins anterior in position. The pelvic fins are often many-rayed, and the pelvic bones are not directly attached to the pectoral arch,

BY COURTESY OF U.S. DEPARTMENT OF COMMERCE, BUREAU OF FISHERIES

COD FLAKE YARD, WHERE THE FISH IS SPLIT, SALTED AND DRIED

The greater part of the season's catch in Newfoundland and Norway, the chief cod fisheries of the world, is cured. The split portions are cod flakes

these characters distinguishing the Anacanthini from certain Blennioid fishes of the order Percomorphi, with which they were formerly associated, and indicating their relationship to more primitive orders. The Anacanthi include two principal families, the *Macruridae*, which are deep-sea fishes without a caudal fin and with the long second dorsal and anal fins continued to the end of the tapering tail, and the *Gadidae*, in which the caudal fin is composed mainly of dorsal and anal fin-rays, the homocercal fin being greatly reduced, an indication that the ancestral form may have been eel-shaped. The *Gadidae* are marine with the exception of the burbot (*Lota lota*), which is a freshwater fish. They are most abundant in northern seas, where there are several species of great economic importance, *e.g.*, cod, haddock (*q.v.*), whiting (*q.v.*), ling (*q.v.*), and hake (*q.v.*). In warmer seas there are some deep-water forms of no great value, and the hake genus (*Merluccius*) is the only important one represented in both the north and south temperate zones. The flesh of all these fishes is more digestible than nutritious, being poor in fat.

The cod (*Gadus morhua*) is common with other fishes of the genus *Gadus*, has three dorsal and two anal fins; the upper jaw projects beyond the lower, and there is a barbel at the chin. The colour varies considerably, but is generally olive-green above with darker spots, and white below; the lateral line is white and conspicuous. The cod is found in the north Atlantic and Baltic but not in the Mediterranean; it also occurs in the north Pacific. Generally it lives on the bottom at depths of 10 to 100 fathoms, and feeds on other fishes, such as herring and sand-eels, and also on squids, mussels, whelks, etc. The spawning season is from January to March; the eggs are minute and are produced in enormous numbers, sometimes 10,000,000 from one female; they float in the water. The young fish attain a length of about two feet in four years; three feet is an average size, but some grow to more than five feet long and weigh over 100lb. The cod is the object of extensive fisheries by line and trawl on the Newfoundland banks, off Iceland and in the North Sea. The greater part of the catch is split, salted and dried; the livers are used for the preparation of cod-liver oil, and the roes are sent to France to be used as groundbait in the sardine fishery; isinglass is made from the air-bladder.

(C. T. R.)

C.O.D.: see CASH ON DELIVERY.

CODA, in music, a term for a passage which brings a movement or a separate piece to a conclusion. (Ital. for "tail"; from the Lat. *cauda*.) This developed from the simple chords of a cadence into what is often an elaborate and important feature of a composition on a large scale. Beethoven raised the "coda" to a feature of the highest importance. A codetta (diminutive of coda) is merely a small coda, employed to round off, not a complete work, but an intermediate section of it.

CODDE, PIETER (1599–1678), Dutch painter of the school of Haarlem, was born on Dec. 11, 1599, at Amsterdam. He was probably a pupil of Franz Hals, whose painting of the Doelen of "Captain Reaels," left unfinished in 1637, he was asked to complete. He was active as a genre painter at Amsterdam and Leyden, and he liked to represent ladies and gentlemen dancing—Sievers' Collection, Dorpat (1627); Mauritshuis, The Hague (1636); Academy in Vienna (1633), or scenes with soldiery—Mauritshuis, The Hague (1628); Dresden Gallery (1628). He also executed some small portraits (National Gallery, London). He died at Amsterdam on Oct. 12, 1678.

CODDINGTON, WILLIAM (1601–1678), one of the founders of Rhode Island, was born in Lincolnshire, England. He was sent out to the colony at Massachusetts bay as a magistrate, arriving at Salem on June 12, 1630. He was for some time treasurer of the colony, and is said to have built the first brick house in Boston. He supported the cause of Anne Hutchinson, the antinomian, and when she was exiled he left, in 1638, for Rhode Island. His name appears first in the covenant of the settlers (*see* RHODE ISLAND). When Portsmouth and Newport were united (1640) Coddington was appointed the first governor, and he was president of the colony in 1648–49. During his year of office he tried, without success, to secure the inclusion of Rhode Island in the confederacy of the United Colonies of New England. He was again governor in 1674–76. He died on Nov. 1, 1678.

CODE. By codification is now meant "an orderly and authoritative statement of the leading rules of law on a given subject" (Ilbert), but the early collections of laws known as codes were of a different character. "The ancient codes" (wrote Maine) "were doubtless originally suggested by the discovery and diffusion of the art of writing. . . . Their value did not consist in any approach to symmetrical classification, or to terseness and clearness of expression, but in their publicity. . . . They mingled up religious, civil and merely moral ordinances without any regard to differences in their essential character." The oldest known code is that of Khammurabi, for which *see* BABYLONIAN LAW. In ancient India the laws applying to the Hindu community of the time were codified.

Roman law began with the Twelve Tables—a primitive code—and culminated in the code of Justinian, which was given the force of law in A.D. 529. (*See* ROMAN LAW.) "Though the name was invented and used in a somewhat different sense by the Romans, the thing is of far more modern origin. . . . The Romans never advanced beyond a digest," whereas, properly, "a code is a digest of which every title has been consolidated" (Holland). The peoples who overran the Roman empire made collections of rules of law, *e.g.*, the law of the Salian Franks and other Frankish laws. (*See* SALIC LAW; GERMANIC LAWS, EARLY.)

The Rhodian Sea-Law was a collection of rules of maritime law, mainly derived from local customs, originally put together between A.D. 600 and 800. Collections of maritime usages and customs, drawn up for the use of merchants and lawyers, acquired in the 14th and 15th centuries great authority throughout Europe. Some were compiled in Mediterranean ports, and others for the use of merchants trading in the north of Europe. There were, for instance, the laws of Oleron (an island near Bordeaux), the laws of Wisby in Gothland, the *Consolato del Mare* (a collection of the maritime laws of Barcelona), the Oak Book of Southampton, and other collections.

Mediaeval France was divided into *Pays de Droit Ecrit* and *Pays de Droit Coutumier*. In the former, feudal rules overlay the Roman law; in the latter, customs differed in each province, county and municipality. Despite the promulgation of a series of ordinances, an extraordinary diversity of laws continued until,

after the Revolution, they were superseded by the Codes Napoleon which were then drawn up. (See CODE NAPOLEON.)

Several European countries have modelled their codes upon those prepared in France under Napoleon, but in Germany events followed an independent course. From 1495 the German common law was a modified form of Roman law, but it was subject to modification by local customs, codes and State laws. Prussian common law was codified in 1794, this step being to some extent an anticipation of the idea of the French codes. With the formation of the North German Federation in 1866 federal legislation began and a general commercial code was enacted. In 1874 (three years after the formation of the German empire) preparations for general codification commenced. After many revisions the German civil code came into force in 1900 and along with it a remodelled commercial code.

The steps taken in more recent years towards the codification of law, not only in England but also elsewhere, originated in the reforming energy of Jeremy Bentham (1748–1832). Bentham's philosophy of law did not take sufficiently into account the march of events either in the past or in the future. He lived before it had become the practice to work by methods which include historical research, and he did not sufficiently appreciate that there is no finality in law, that it must be revised from time to time as circumstances change. Nevertheless, in this matter he was a great moving spirit. "What he did was to set up an ideal towards which legislation should tend, an ideal which has been materially modified by subsequent reflection and experience, but which has profoundly influenced the thought and action of lawyers and legislators since his time. He has not shown the necessity, but he has shown the utility, of codification" (Ilbert).

In British India the codification of the law may be attributed directly to the influence of Bentham exercised through James Mill and Macaulay. The penal code became law in 1860 and was followed by two codes dealing with procedure, and, in course of time, by a number of others on various branches of the law.

Following earlier attempts made in England to improve the form of the law, a number of statute law commissions were appointed during the earlier part of the Victorian period. Various reforms resulted, and many consolidation acts were passed, dealing with, e.g., the customs, public health, merchant shipping, and so forth. With lapse of time the need for re-consolidation, so as to incorporate later amendments, manifested itself, and from the beginning the process in most instances fell short of full codification because consolidation covered only statutory provisions and did not extend to common law rules. In more recent years some measures have been passed codifying both the statute and the common law relating to particular subjects, e.g., the Bills of Exchange Act, 1882, the Partnership Act, 1890, the Sale of Goods Act, 1893, and the Marine Insurance Act, 1906.

English law is the basis of the law in force in most of the States of the United States, an exception being Louisiana, where a civil code based on the Code Napoleon was adopted in 1808. Much codification of law was carried out in many of the States during the latter part of the 19th century, the first move in this direction being the adoption of a code of civil procedure by the State of New York in 1848. The laws of the South American republics have for the most part been codified.

In Egypt a series of codes came into force in 1875. Japanese law has been codified on the basis of an investigation into the laws of European countries which extended over the greater part of the last quarter of the 19th century. The civil code (which is now the main foundation of the Japanese legal system), and the commercial code are largely modelled on German law.

International Codes.—Besides the codification of national laws something has been done towards codifying rules of law regulating the relations between States and between the subjects of different States. These rules are commonly referred to as those of public and private international law respectively. The advisory committee of jurists which met at The Hague in 1920 to draft the plan for the Permanent Court of International Justice recommended that, in continuation of The Hague Conferences of 1899 and 1907, steps should be taken to bring about the re-statement

of the established rules of international law and the formulation of additional rules. Pursuant to this the League of Nations in 1924 appointed a committee of experts for the progressive codification of international law composed of jurists from 17 countries.

This Committee reported in 1927 and is continuing its work. Pursuant to its recommendations a first codification conference was held at The Hague in 1930 to consider (1) nationality, (2) territorial waters and (3) responsibility of States for damage done in their territory to the person or property of foreigners.

Proposals for codification of international law have aroused much interest in America. In 1906 the third Pan-American Conference adopted a convention under which codes of private and public international law were to be prepared. At later meetings of the Pan-American Conference (including that at Havana in 1928) further discussion of projects of conventions has taken place.

On the subjects selected for the first codification conference of 1930 as well as other possible subjects for the work of codification the progress which may prove to be practicable will be due in large measure to unofficial spade work done in the past by the Institute of International Law and the International Law Association. These, since 1873, have been busy with the problems to which Governments have more recently turned their attention. Since 1896 their activities have been supplemented by those of the Comité Maritime International, and since 1905 by those of the American Society of International Law.

The official movements above referred to have not yet brought about any actual codification of rules of law of international application, but in certain directions codification or unification has already been accomplished. In the absence of an international legislature no actual codification by means of international legislation is possible, but an equivalent result has been produced in relation to certain matters by national legislation being passed in conformity with an international convention, or (in some commercial matters especially) unification has been achieved by the formulation and common adoption of standard clauses for incorporation by reference in contracts. In this way the International Law Association brought about the unification of some of the rules of law and practice relating to general average. International rules drawn up for this purpose and incorporated by reference in shipping documents are known as the York-Antwerp Rules. The first rules adopted were those dated 1877. They were revised in 1890 and in 1924 were again revised and expanded into what is practically a code of general average (see AVERAGE). On the other hand the regulations for the prevention of collisions at sea, having been adopted by all maritime nations, are an example of standardized national legislation. Working after this method, the Comité Maritime International has drafted international conventions, some of which have been carried into effect by national legislation, while others await further action by maritime States. In the United States steps to standardize certain commercial laws throughout the different States of the Union have brought about the passing of uniform acts relating to negotiable instruments, sale of goods, bills of lading, warehouse receipts, etc.

CODEINE occurs naturally in opium, being one of the alkaloids (q.v.) of the phenanthrene group and a derivative of morphine (q.v.), retaining in a modified form the characteristic physiological action of the latter. It crystallizes with one molecule of water, $C_{18}H_{21}O_3N \cdot H_2O$, in large translucent prisms, melts at $155^\circ C$ and has a specific rotation $[\alpha] -137.7^\circ$. It behaves as a mono-acidic base, forming salts of which the sulphate and the phosphate are those most frequently used in medicine.

CODE NAPOLEON, the first code of the French civil law, known at first as the *Code civil des Français*, was promulgated in

its entirety by a law of the 30th Ventose in the year XII. (March 21, 1804). On Sept. 3, 1807, it received the official name of Code Napoléon, although the part that Napoleon took in framing it was not very important. A law of 1818 restored to it its former name, but a decree of March 27, 1852, re-established the title of Code Napoléon. Since Sept. 4, 1870, the laws have quoted it only under the name of the Code Civil.

Never has a work of legislation been more national in the exact sense of the word. Desired for centuries by the France of the *ancien régime*, and demanded by the *cahiers* of 1789, this "code of civil laws common to the whole realm" was promised by the constitution of 1791. However, the two first assemblies of the Revolution were able to prepare only a few fragments of it. The preparation of a coherent plan began with the Convention. The *ancien régime* had collected and adjusted some of the material. There was, on the one hand, a vast juridical literature which by eliminating differences of detail, had disengaged from the various French "customs" the essential part which they had in common, under the name of "common customary law"; on the other hand, the Roman law current in France had in like manner undergone a process of simplification in numerous works, the chief of which was that of Domat; while certain parts had already been codified in the *Grandes Ordonnances*, which were the work of d'Aguesseau. This legacy from the past, which it was desired to preserve within reason, had to be combined and blended with the laws of the Revolution, which had wrought radical reforms in the conditions affecting the individual, the tenure of real property, the order of inheritance and the system of mortgages. Cambacérès, as the representative of a commission of the Convention, brought forward two successive schemes for the Code Civil. As a member of one of the councils, he drew up a third under the Directory, and these projected forms came in turn nearer and nearer to what was to be the ultimate form of the code. So great was the interest centred in this work, that the law of the 19th Brumaire, year VIII., which, in ratification of the previous day's *coup d'état* nominated provisional consuls and two legislative commissions, gave injunctions to the latter to draw up a scheme for the Code Civil. This was done in part by one of the members, Jacqueminot, and finally under the constitution of the year VIII., the completion of the work was taken in hand. The legislative machinery established by this constitution, defective as it was in other respects, was eminently suited for this task. Indeed, all projected laws emanated from the Government and were prepared by the newly established Council of State, which was so well recruited that it easily furnished qualified men, mostly veterans of the Revolution, to prepare the final scheme. The Council of State naturally possessed in its legislative section and its general assembly bodies both competent and sufficiently limited to discuss the texts efficiently. The *corps législatif* had not the right of amendment, so could not disturb the harmony of the scheme. It was in the discussions of the general assembly of the Council of State that Napoleon took part, in 97 cases out of 102 in the capacity of chairman, but, interesting as his observations occasionally are, he cannot be considered as a serious collaborator in this great work.

Those responsible for the scheme have in the main been very successful in their work; they have generally succeeded in fusing the two elements which they had to deal with, namely ancient French law, and that of the Revolution. The point in which their work is comparatively weak is the system of hypothec (*q.v.*), because they did not succeed in steering a middle course between two opposite systems, and the law of March 23, 1855 (*sur la transcription en matière hypothécaire*) was necessary to make good the deficiency. A fault frequently found with the Code Civil is that its general divisions show a lack of logic and method, but the division is practically that of the *Institutes* of Justinian, and is about as good as any other: persons, things, inheritance, contracts and obligations, and finally, in place of actions, which have no importance for French law except from the point of view of procedure, privileges and hypothecs, as in the ancient *coutumes* of France, and prescription. It is, *mutatis mutandis*, practically the same division as that of Blackstone's *Commentaries*.

Of late years other objections have been expressed; serious omissions have been pointed out in the code; it has not given to personal property the importance which it has acquired in the course of the 19th century; it makes no provision for dealing with the legal relations between employers and employed which modern complex undertakings involve; it does not treat of life insurance, etc. But this only proves that it could not foretell the future, for most of these questions are concerned with economic phenomena and social relations which did not exist at the time when it was framed. The code needed revising and completing, and this was carried out by degrees by means of numerous important laws. In 1904, after the celebration of the centenary of the Code Civil, an extra-parliamentary commission was nominated to prepare a revision of it, and at once began the work.

(J. P. E.)

Dissemination of the Code.—The influence of the Code Civil has been very great, not only in France, but also abroad. It should be remembered that when the Revolution broke out France had for a century and a half held, almost without a rival, the leading place among the nations of the world. Her language was well on the way to succeeding Latin as the common speech of civilized men; her literature, her arts, the fascination of her culture, the splendour of her capital city, the devotion of her missionaries, held all mankind spell-bound. Yet her law had no admirers or imitators in other countries. Few foreigners thought it worth while to study her meagre legal literature; few students from abroad sought admission to her law-schools. The Revolution and the empire, by the alarm which they excited and by the spirit of nationalism which they stimulated in other countries, went far to forfeit for France the pre-eminence which she had won and was winning by peaceful penetration. But the code saved the situation; and ever since its promulgation (March 21, 1804), France has exerted an incomparable influence upon the institutions and legal culture of the civilized world. Indeed, until the promulgation of the German civil code (Aug. 24, 1896) the Code Napoléon has been without a competitor as a model for law reformers throughout all parts of the world outside the British empire and the United States. In the absence of an English code, the English common law has, in spite of the great place which it occupies, found acceptance in no country outside the circle of those which, by reason of conquest, or of colonization, possess English-speaking rulers. The 19th century was pre-eminently an age of nation-making. In Europe it saw the creation or the unification of Germany, Italy, Belgium, Rumania, Bulgaria and Greece; on the American continent it saw the Spanish and Portuguese colonies transformed into 15 new nations; and in the East it witnessed Japan, Siam, Turkey and Egypt attempting with greater or less success to grasp the secret of European pre-eminence. Of these 25 nations almost all sought to mark their succession to political maturity, and to proclaim their adherence to the European world, by a general revision and codification of their laws; and in most cases the model followed was that furnished by the Code Napoléon. The code was attractive in form; it was written in French; it was, or seemed to be, easy to understand; it bore the name of the greatest man of the age; it claimed to be catholic, rational, imperial and universal; it was secular without being irreligious and democratic without being revolutionary. In short, according to the ideas of 19th-century liberalism, it set forth in chapter and verse the fundamental articles of the social contract.

Nor did the code have to rely upon its intrinsic merits alone. The reorganization of the French educational system, and particularly of the universities, which constituted one of Napoleon's principal achievements, created law-schools which in their turn produced an imposing literature of exposition and commentary on the code. This literature has been an important factor in promoting the adoption and assimilation of the code by foreign countries.

The Napoleonic Empire.—When first promulgated in 1804, the French code came automatically into force in all those countries which were at that time subject to the empire. These were Belgium, Luxemburg, the Palatinate, those parts of Rhenish Prussia and Hesse-Darmstadt which were situated on the left bank of

the Rhine, the territory of Geneva, Savoy, Piedmont and the duchies of Parma and Piacenza. Napoleon subsequently promulgated the code in the following countries as they were successively conquered: Italy (by decree of March 30, 1806); Holland (Oct. 18, 1810), the Hanseatic departments (*senatus-consultum* of Dec. 13, 1810); grand duchy of Berg (decree of Dec. 17, 1811). The following countries adopted the code *proprio motu*, though doubtless under some pressure, before the fall of the empire: Westphalia, Hanover, the grand duchies of Baden, Frankfurt, Nassau and Warsaw, several of the Swiss cantons, the free city of Danzig, the Illyrian provinces and the kingdom of Naples.

The blows delivered at Leipzig (1813) and Waterloo (1815) to French prestige gave a check, but only for a short time, to the dissemination of the code. In many parts of Italy, for example, the Restoration Governments revived the old laws; but they were speedily compelled to recognize that the clock could not be put back in so violent a fashion, and to revert to codes on the French model. The code of the two Sicilies (1819), the code of Parma, promulgated by the ex-empress, Marie-Louise, in 1820, the important Sardinian or "Albertine" code promulgated for Piedmont in 1848, and the civil code of Este (1851) all bear the mark of French influence. These essays in legislation led up to and were replaced by the general civil code for the new kingdom of Italy which came into force on Jan. 1, 1866. The similarity of this code, which is still in force, to the French code is particularly marked in all those parts in which both remain closest to Roman law, *i.e.*, in the sections treating of obligations and real rights. The degree of this similarity may be judged by the fact that for some years past a committee composed of French and Italian jurists has been engaged in the preparation of drafts with a view to a uniform revision of those parts of the two codes which relate to the law of obligations.

Europe After Waterloo.—The restitution, after Waterloo, of their possessions on the left bank of the Rhine, to Prussia and the German States, was not followed by the abandonment of the French code, which remained in force until replaced in 1900 by the general code for the German empire. In Baden the Code Napoléon was transmuted and preserved, without substantial change, in the *Badisches Landrecht* and in this form had a similarly long lease of life. The code not only remained in force in this country, but was the subject of influential exposition. The *Commentary* of Zachariae, a Heidelberg professor, published in 1808 was the first general treatise on the code in any language. Not only was it destined to reappear in numerous successive editions in German, but it served as the basis for the French *Commentary* of Aubry and Rau, of which the last edition, completed in 1922, still bears on the title page "d'après la méthode de Zachariae." Puchelt's *Zeitschrift für französisches civilrecht*, founded in 1870 and published at Mannheim, continued to appear till early in the present century.

Egypt.—Egypt offers an example of the reception not only of the Code Civil, but of its four companion codes, by a people totally alien to Europe in all cultural traditions. When, in 1874, the Egyptian Government obtained the consent of the Powers to the institution of the mixed tribunals, it was agreed without debate that the only possible law with which to equip them was that of the French code. The Code Civil, as adapted for application by the new tribunals, was shorn of all matters relating to personal status and to the effects on property of marriage and death. In 1883, the year following the British occupation, the French codes were extended, in a form almost identical with that adopted by the mixed courts, to the newly organized native jurisdiction. The result of this twofold "reception" of the French codes has been that for the last 50 years Egypt has looked to French text-books, to French judicial decisions and in a large measure to French professors, for the progressive elucidation of the law. It is largely for this reason that in spite of the British occupation the social and cultural influence of France has remained supreme in that country. It has been remarked that proposals for innovation made by English advisers have as often met with opposition on the ground that they offended against the principles of French law as on the ground that they trespassed against the sacred law of

Islam.

Japan.—The course of events in Japan has been different, and even more instructive. One of the first acts of the Restoration Government, so early as 1870, was to cause the Code Napoléon to be translated, and to send for French jurists to supervise the administration of justice and to organize legal education. Though not promulgated as law, the French code in this way and in the absence of any serious rival, either indigenous or foreign, acquired great authority from the beginning of the new regime. In 1880 there was published a draft civil code, prepared by M. Boissonade, a member of the French legal mission. This code, though it, too, was not promulgated as law, exercised for 16 years as great an influence in the country as if it had been legally in force, and was treated by the judges as a statement of the principles of natural reason and equity. Meanwhile, concurrently with the academic teaching of French law, provision had been made by the Japanese Government for instruction in Anglo-American law at the University of Tokyo.

In 1892 M. Boissonade's code was on the eve of being put into force, when the Diet voted that it should be submitted to a further revision. This decision appears to have been due to dissensions between the French and English schools of legal thought. The result was that when the revised code was finally promulgated in 1896 it was found to be neither English nor French but German in inspiration.

Competition of German Civil Code.—This *dénouement* was symbolic. The German civil code, published in its final form in 1895, was the first serious rival which Napoleon's code had had to encounter. As compared with its French predecessor, the German code had the advantage derived from a century of progress in legal science; it was a more carefully thought out piece of work; it was greatly superior in arrangement; it distinguished more clearly between substance and accident, between principle and application; in short, it was a more scientific piece of work. There are strong indications that it may now be taken to have replaced the French code as the model for future essays in codification. The Swiss civil code, for example, which bears date Dec. 10, 1907, is largely modelled on the German code, though in form it is shorter and simpler. The Turkish republic has recently adopted it, almost without alteration, as the civil code of Turkey.

CODES AND CIPHERS, general terms designating the methods employed in the practice of cryptography, or secret writing; often also used to designate the cryptograms produced thereby. In recent years, because of the growth of governments, the expansion of commerce, and especially the remarkable progress made in the art of electrical communications, they have become essential adjuncts to the conduct of diplomatic, naval, military and commercial affairs.

The final text of cryptograms to be transmitted electrically should, for reasons of practicability, be composed exclusively of letters of the alphabet, and, for reasons of economy, be arranged in regular groups of five or ten letters; cryptograms composed of groups of figures, although acceptable, are more costly and therefore not so common; those composed of intermixtures of letters and figures are rarely encountered, and those containing characters other than letters or figures are not accepted for transmission. Although in theory no sharp line of demarcation can be drawn between code systems and cipher systems, in modern practice the technical differences between them are sufficiently marked to warrant their being treated as separate categories of methods. It is convenient to consider cipher systems first, then code systems, with the understanding that only a very few of the limited number of systems suitable for serious usage can here be outlined.

Cipher Systems.—In general, cipher systems involve a cryptographic treatment of textual units of constant length, usually single letters, sometimes pairs, rarely sets of three letters, these

being treated as symbols without reference to their identities as component parts of words, phrases and sentences. Every practical cipher system must combine (1) a basic method of treatment which is constant in character, with (2) a keying principle which is variable in character and employs specific secret keywords, phrases, or numbers, the individual compositions of which determine or control the exact results under the basic method. The basic method must be such that even if known to the "enemy" no messages can be read by him unless he also knows the specific keys applicable to those particular messages.

Despite a great diversity in the external appearance and internal constitution of ciphers, there are only two basic classes of systems, transposition and substitution. The former involves a rearrangement or change in the sequence of the plain-text letters, without any change in their identity; the latter, a replacement of the plain-text letters by other letters or by figures, without any change in their original sequence. The two systems may be combined in a single cryptogram.

Transposition systems usually involve the inscribing of plain-text letters in a more or less regular geometrical design, beginning at a prearranged initial point and following a prescribed route, and then transcribing the letters from the design, beginning at another prearranged initial point and following another prescribed route. The design may take the form of a rectangle, trapezoid, octagon, triangle, etc., but systems in which the specific keys consist solely in keeping the designs, the initial points, and the routes secret are not often employed because of their limited variability. In this same class also fall systems which employ perforated cardboard designs called grilles, descriptions of which will be found in works listed in the bibliography. The system most commonly used in practice is that designated as columnar transposition, wherein the transposition design takes the form of a simple rectangular figure, the dimensions of which are determined in each instance jointly by the length of the individual message and the length of the specific key. An example is shown in fig. 1.

Key: **TELEGRAPH** Cryptogram: **ENEET FTARR CYETE AINLU UIPTR DUHDR LO**

Fig. 1.—An example of simple columnar transposition. The numerical key is derived by numbering the letters of the keyword ("telegraph") in accordance with their relative order of appearance in the ordinary alphabet, repeated letters, if present in the key, being numbered in sequence from left to right. The message is written in the normal manner from left to right in successive horizontal lines underneath the key, forming a "rectangle" of columns of letters. These letters are then transcribed in regular groups of five from the rectangle by reading down the columns, taking the latter in the sequence indicated by the key numbers. The last line of the rectangle may be completely filled with letters, nonsignificants being added if necessary; but the security of the method is considerably increased if the last line shows one or more blank spaces, as in this example.

In the foregoing case the letters undergo a single transposition; in cases involving double transposition, that is, wherein the letters undergo two successive transpositions, the security of the cryptograms is very greatly increased, provided the methods selected are such as will effectively disarrange individual letters and not merely whole columns or rows. A practical system of double transposition is illustrated in fig. 2.

The principal advantages of transposition systems lie in their comparative simplicity, speed of operation, and, in the case of true double transposition, their high degree of security; but despite these important considerations they do not at the present time play a prominent rôle in practical cryptography because of certain defects inherent in and common to all methods of transposition.

Substitution systems involve the use of conventional alphabets called substitution alphabets or cipher alphabets, and the complexity of any particular system depends upon three conditions: (1) the nature of the cipher alphabets employed, (2) the number of them involved in a single cryptogram, and (3) the specific

Fig. 2.—An example of true double transposition. The cipher letters resulting from the first transposition rectangle (a) are written under the key of the second transposition rectangle (b) just as though they constituted plain-text, that is, from left to right, in successive horizontal rows. The final transposition is then performed in exactly the same manner as in fig. 1, yielding five-letter groups. The two rectangles may be based upon the same keyword, as in this example, or upon wholly different keywords.

manner in which they are used in the enciphering process. As to their nature, cipher alphabets are of various types, and are known under various names, such as standard, direct, reversed, systematically-mixed, keyword-mixed, random-mixed, reciprocal, conjugate, etc., all having reference to the nature of the sequences of letters composing them, their manner of production, the interrelations existing among them internally or externally, etc. The most important factor in connection with a cipher alphabet is whether the sequence, regardless of its nature, is known or unknown to the enemy; for if its sequence is known, any conventional or disarranged alphabet may be handled with the same facility as the normal or ordinary alphabet. As to the number of alphabets involved, substitution systems are either monoalphabetic, involving a single alphabet, or polyalphabetic, involving two or more alphabets. In essence the difference between them lies in the fact that in the former the equivalence between plain-text and cipher letters is of a constant or invariable nature throughout the cryptogram, whereas in the latter it is of a changing or variable nature. So far as secrecy is concerned, the third condition mentioned above, the manner in which the various cipher alphabets are employed, is the most important.

Monoalphabetic systems, an example of which is shown in fig. 3, can be passed over in a few words. They represent the simplest

Fig. 3.—An example of monoalphabetic substitution. Each letter of the message is replaced by its equivalent as given in the cipher alphabet. The latter is a good example of a systematically-mixed alphabet, derived from an easily remembered word, in this case "Gettysburg." The keyword is written on one line, repeated letters, if present, being omitted, and the remaining unused letters of the ordinary alphabet are written in horizontal lines below the keyword. The numerical key (32685174) is derived from the first line. The resulting incomplete rectangle of 26 letters is then treated exactly as in figure 1, yielding the sequence BIQUECMZ . . . which is then written under the ordinary alphabet and forms the cipher alphabet.

types of substitution and, regardless of the type of cipher alphabet employed, practically every example can be readily solved by the well-known principles of frequency.

The foregoing example illustrates monoalphabetic substitution which is monoliteral in character, that is, each letter is replaced by another single letter; biliteral monoalphabetic substitution, where each letter is replaced by a pair of letters, is sometimes encountered, and is illustrated in fig. 4.

Polyalphabetic systems are often referred to as double-key systems, and, as noted above, employ two or more cipher alphabets

Fig. 4.—An example of bilateral, monoalphabetic substitution. A keyword alphabet of 25 letters (I serving also for J) is written in a square 5 x 5. (In this case the alphabet is based upon the word "telegraph.") The letters (A, B, C, D, E) at the side and top of the square, taken in pairs, can then be used to represent the letters within the square. Thus, D = CA, E = AB, etc. The letters at the side of the square may be the same as or different from those at the top; in both cases keywords, identical or different, may be used instead of the letters A, B, C, D, E.

in the encipherment of single dispatches. In a given system the alphabets may be entirely independent of and bear no relation to one another, or they may be interrelated. In the former case their number may be unlimited, the separate alphabets being drawn up at random and arranged in any convenient manner; in the latter case the alphabets are limited in number and are interrelated because they are secondary alphabets derived by juxtaposing two basic or primary alphabets at the 26 possible points of coincidence and noting the 26 different values given for plain text A, B, C . . . Z, for the 26 successive juxtapositions. In the simplest case of interrelated alphabets, that resulting when the two primary alphabets are both normal sequences, proceeding in the same direction, the secondary alphabets are called standard alphabets, which when successively tabulated yield a symmetrical table (fig. 5) known in the literature under various names such as Vigenère table, square table, quadrilateral table, etc. Such a table may be used in several ways. The most common method employs the top line as the plain-text alphabet and the successive horizontal lines as the cipher alphabets, each of which may be designated by its initial letter. Thus, the fourth or D alphabet is the one in which plain-text A is represented by cipher D, plain-text B, by cipher E, etc. In the ninth or I alphabet, A=I, B=J, etc. Therefore, when several alphabets are to be employed in a message, the letters of a prearranged keyword can serve to indicate the number, identity, and sequence of the alphabets to be selected.

Fig. 5.—The simple Vigenère table. The cipher equivalent of a given plain-text letter enciphered by a given key letter is that letter which stands at the intersection of the vertical column headed by the former and the horizontal row begun by the latter. Thus, plain-text letter E enciphered by key letter M yields cipher letter Q, or, in brief notation, $E_p(M_k)=Q_c$; $E_p(X_k)=B_c$, etc.

Various modifications of the simple Vigenère table are encountered, these involving different types and arrangements of alphabetic sequences in the table, but in every case where these

sequences can be arranged so as to exhibit symmetry of position as regards the order in which the letters fall in the successive rows or columns, sliding or concentric primary alphabets may be employed to produce the same results as the table, and are often more convenient than the latter.

Polyalphabetic substitution systems may be classified as periodic or aperiodic, depending upon whether or not the cryptograms produced by them exhibit external phenomena of a cyclic nature. Periodicity is exhibited externally whenever the substitution process involves the use of repeating keying elements which operate in conjunction with a constant number of cipher alphabets. Periodic systems may be further classified into multiple alphabet and progressive alphabet systems. In the former type only limited numbers and specific members of the complete set of alphabets pertaining to the system are employed in a single message, the number, sequence and identities of the alphabets being governed in each case by the key, which is repeated as often as necessary to encipher the message. An example is shown in fig. 6.

In progressive systems all the cipher alphabets pertaining to the system are employed in succession in a single, definite se-

| Cipher: | E V H R X I B M M P S R K V Q C B M S B |

Fig. 6.—An example of multiple alphabet substitution. The alphabets of the simple Vigenère table (fig. 5) are used in conjunction with the keyword TROY, which is written above the plain text and repeated as many times as required. Each letter is then enciphered by the keyletter above it. Thus, for the first letter, $L_p(T_k)=E_c$; for the second letter, $E_p(R_k)=V_c$, etc. Usually all the plain-text letters governed by the first letter of the key are enciphered in succession, then those governed by the second, etc., this method reducing the possibility of error. In practice, the keyword, and therefore the period, is usually longer than that employed in this example, words and phrases of 15 to 20 or more letters being common. Much more important, however, is the fact that the alphabets employed in modern times are seldom those of the simple Vigenère table, but are mixed alphabets, the use of which makes the cryptograms more secure against solution.

quence which may be repeated. Hence, the length of the period corresponds to the total number of cipher alphabets involved in the system. Usually the sequence in which the alphabets are used varies with each message, this constituting one of the important factors in secrecy. To illustrate, suppose the system embodies a set of 50 mixed alphabets, each designated by a number. A numerical key consisting of the numbers from 1 to 50, constructed either by random selection or by derivation from a word, phrase or sentence, is employed to control the sequence in which the alphabets are to be used in enciphering a specific message; if the latter contains 500 letters, the sequence passes through 10 cycles. Another message may be enciphered by a different numerical key; with 50 alphabets the total number of different numerical keys possible is $50 \times 49 \times 48 \times \dots \times 1$, an extraordinarily great number.

Polyalphabetic systems of the aperiodic type present the greatest diversity in construction. In these systems periodicity is either entirely lacking because of the inherent nature of the method, or it is suppressed by incorporating variable elements as period interrupters. In the aperiodic system designated as the running or nonrepeating key system, periodicity is avoided by employing for the key the continuous text of a book, identical copies of which are in possession of the correspondents. The starting point of the key is agreed upon in advance, or is signalled by special indicators to designate the exact point where the key begins. Another type of nonrepeating key system, often designated as the auto-key system, is that in which, beginning with a preconcerted keyletter, each cipher letter (or sometimes each plain-text letter) becomes the keyletter for the encipherment of the next plain-text letter.

Among the systems in which periodicity is suppressed by introducing a variable element, or interrupter, one of the simplest is that wherein encipherment is performed according to word lengths, each letter of the key serving to encipher a complete word by the same alphabet. Words being irregular in length, periodicity is suppressed. Another system, called the interrupted-key method, employs a keyword which is broken at irregular intervals by a

subsidiary key, or by the insertion of a specially agreed upon letter serving as an indicator. Thus, using the keyword WEDNESDAY, a message may be enciphered according to the interrupted key WED/WEDNES/WE/WEDN/WEDNESD, etc. If a special indicator is used, the interrupter may be inserted at will, since in decipherment its reappearance serves to indicate where the breaks in the keying sequence occur. Sometimes a prearranged plain-text letter serves as the interrupter itself; sometimes a cipher letter.

The various systems of substitution thus far mentioned are monographic in nature, involving single letters; in digraphic systems, substitution takes place by pairs, usually by means of squares in which the letters of the alphabet are disposed according to agreement and the cipher equivalents of pairs are found by following certain rules. One of the best known methods is that called the Playfair method, illustrated in fig. 7.

Fig. 7.—The Playfair cipher; an example of digraphic substitution. An alphabet square of 25 letters (I serving also as J) based upon a keyword (in this case "Lexington") is drawn up, and substitution is performed with pairs of letters. Three cases as regards the position occupied in the square by the members of a pair are possible; they lie (1) in the same horizontal row, or (2) in the same vertical column, or (3) at the opposite ends of one of the diagonals of an imaginary rectangle. By studying the following examples under each case the method of finding equivalents will become apparent: Case (1) LI=EN, AB=BG, OB=AG; Case (2) ED=TP, EV=TE, PV=VE; Case (3) ER=IP, IM=LR, ST=PB. The text of the message to be enciphered, line 1 in the figure, is divided up into pairs, line 2. Double-letter pairs in the text are to be separated by an interposed letter such as X, as shown in the case of the word "following" in this example. Note also the addition of the letter "X" to the end of the message in order to make a pair of letters. The cipher equivalents are shown in line 3, the final cryptogram in five-letter groups, in line 4. Various arrangements of letters in the alphabet square are possible, and completely disarranged alphabets may be employed.

Properly selected methods of transposition and substitution when combined into a single system result in the production of cryptograms of great security, but because of the additional complexities of operation introduced by the combination, with the resultant increased possibilities of error, such systems are not often encountered in practice. A good example, ingenious because of its simplicity and security, is that illustrated in fig. 8.

Fig. 8.—An example of a combined substitution-transposition cipher. The substitution method of fig. 4 is here combined with the transposition method of fig. 1. The substitution square (1) is used in enciphering the text by substitution. The cipher equivalents of this step are then written under a key forming a transposition rectangle (2) and simple columnar transposition forms the second step, yielding the text of the final cryptogram. The latter text can be brought back to monoliteral terms, if desired, by referring to the substitution square and using it in the reverse manner. Thus, BBAABEBACE would become PIRAM, etc. The keywords for the substitution square and the transposition rectangle may be the same, as in this example, or they may be different.

Cryptographic devices and machines for facilitating cipher

operations have been known for many years; they vary in complexity from simple, superimposed, concentrically or eccentrically rotating disks to large, mechanically or electrically operated type-writing and telegraph apparatus suitably modified for cryptographic purposes. One of the best cryptographs of the more simple, mechanical type is that known as the Bazeries cylinder, named after the Frenchman who is commonly credited with its invention in 1891. The principle upon which the device is based

FIG. 9.—THE BAZERIES CYLINDER

was, however, conceived many years before by Thomas Jefferson (see Jefferson's Papers, Vol. 232, item 41,575). The Bazeries cylinder consists of a set of 20 disks, each bearing on its periphery a different mixed alphabet. The disks, which bear identifying numbers from 1 to 20, are assembled upon a common shaft from left to right according to a numerical key. In encipherment the disks are revolved so as to bring the plain-text letters on a single horizontal line, and then the letters of any other horizontal line are taken as the cipher equivalents. The text is thus enciphered 20 letters at a time. In deciphering, the cipher letters are "set up" upon one horizontal line by revolving the disks and locking them into position. By slowly revolving the whole cylinder and examining each horizontal line, only one of the latter will be found to yield intelligible text. One of the most ingenious of the more complicated types of cipher machines is that embodied in certain printing telegraph apparatus of modern design. In this system electrical encipherment, transmission, reception and decipherment, controlled by perforated tapes, may be accomplished simultaneously at a high rate of speed. Of the many devices and machines that have been invented, constructed and marketed, only a re-

FIG. 10.—ELECTRICAL CRYPTOGRAPH EMPLOYING A TYPEWRITER KEYBOARD

markably small number have ever been, or are now, in use. In general, the degree of secrecy afforded by the types heretofore constructed is not sufficiently high to warrant their adoption for diplomatic, naval or military telegraphic correspondence; and the fact that in international correspondence the cost of transmitting telegrams in cipher language (unpronounceable groups) has for over a quarter of a century been twice that for telegrams in code language (pronounceable groups) has constituted an effective deterrent to the use of cipher machinery in commercial telegraphic correspondence.

Code Systems.—These are simple but highly specialized forms of substitution systems, and the most important developments in them since the advent of electro-magnetic telegraphy have always been either American or British in origin. They merely involve the use of modified conventional dictionaries termed code books, by means of which textual units of variable length—usually whole words, phrases and sentences—can be replaced by arbitrarily assigned signals termed code groups. From the point of view of practical usage to-day, code systems are more important than cipher systems, their simplicity and economy constituting their chief advantages. In encoding a message it is necessary merely to refer to the code book, find the desired words, phrases, sentences, numbers, etc., and replace them by the code groups assigned them, building the message up step by step in the fewest code groups possible. The condensing power of codes, brought about by the fact that a single code group may represent a long word, a phrase, or a complete sentence, depends upon the extent of the code and the skill used in its compilation; an average condensation of 1:5 (that is, one code group replacing five plain-text words) is quite common in commercial codes. The older types of codes employed either dictionary words or figure groups as code equivalents, but since 1904 such codes have been almost completely superseded by codes employing five-letter groups constructed by means of elaborate permutation tables. The most important feature of such a table is that it facilitates the construction of a series of 100,000 or more five-letter, pronounceable, artificial "words," all of which differ from one another in at least two letters. For example, if BERAM is a bona fide member of a given series, there will not be present in the same series any group differing from BERAM in only a single letter, such as CERAM, B/AM, BESAM, BER/M, BERAN, etc. In the latest codes an additional safeguard has been incorporated, having as its object the suppression of errors introduced by the accidental transposition of adjacent letters in a code group. For example, if BERAM is a bona fide member of a given series, there will not be present in the same series any of the following groups: EBRAM, BREAM, BEARM, BERMA. In some codes an attempt is made to suppress errors introduced by the accidental transpositions of alternate letters as well as adjacent letters. These features, though of comparatively recent origin, are very important in that they have greatly increased the accuracy of code communication. The

seems no secrecy. Many business firms, however, have private codes which, if carefully restricted in distribution, may constitute codes that may be regarded as secret except to experts. Governmental codes are, of course, very carefully guarded in their production, distribution and usage. As to their construction, codes may be of the "one-part" or the "two-part" type, the principal difference between them being shown in fig. 12.

| | | |

Fig. 12.—Extracts from typical one-part and two-part codes. In the one-part type the code groups and the vocabulary are arranged in parallel, alphabetic (or numerical) sequences, so that a single book serves for encoding as well as for decoding. In the two-part type the encoding book lists the elements of the vocabulary in alphabetic order but the code groups are in random order, so that a decoding book, in which the code groups appear in alphabetic (or numerical) order accompanied by their meanings, is essential. The degree of secrecy afforded by a code of the latter type is much greater than that afforded by one of the former type, all other things being equal.

When the code words of a simple code message undergo encipherment by a superimposed cipher system the result is termed enciphered code. Its purpose is to afford secrecy, in the case of purchasable commercial codes, or additional secrecy, in the case of private or governmental codes. The superimposition of a suitable cipher system upon code text prepared by means of an extensive two-part code imparts an exceedingly high degree of secrecy to messages and constitutes a practical system much in use by large governments for voluminous correspondences.

The science of solving cryptograms by analysis, having undergone great development in recent years, has been deemed worthy of being designated by a special name, cryptanalysis, to distinguish the indirect methods of reading cryptograms from the much more direct methods, called deciphering and decoding, which imply a knowledge of the basic method and specific key, in the case of ciphers, or possession of the code book, in the case of codes. Apart from the more simple, classical types, nearly every scientifically constructed cryptographic system presents a unique case in cryptanalysis, the unraveling of which requires the exercise of unusual powers of inductive and deductive reasoning, much concentration, perseverance and a vivid imagination; but all these qualities are of little avail without a special aptitude based upon extensive, practical experience. A preliminary requisite to the analysis of a cryptogram is a determination of the language in which its plain text is written, information which is either already at hand in the case of official correspondence, or which, in the case of private correspondence, can usually be obtained from extraneous circumstances. Next comes a determination as to whether a cipher or a code system is involved; this is based upon the fact that differences in their external appearance are usually sufficiently well marked to be detectable by experts. If the cryptogram is in cipher, the next step is to determine whether it belongs to the transposition or to the substitution class. This determination rests upon the fact that in plain text the vowels and consonants are present in definite proportions. Since transposition involves only a rearrangement of the original letters, it follows that if a cryptogram contains vowels and consonants in the approximately normal proportions it is of the transposition class; if not, it is of the substitution class. The solution of transposition ciphers involves much experimentation with geometrical designs of various types and dimensions, clues to which are afforded by the number of letters in the messages and extraneous circumstances. The assumption of the presence of probable words is often necessary. Special methods of solution based upon a study of messages of identical lengths, or with identical beginnings or endings, are often possible to apply when much traffic has been intercepted. Finally, the presence of letters which individually are of low frequency, but which when present have a great affinity for each other and form pairs of moderate or high

FIG. 11.—A PRINTING TELEGRAPH CIPHER MACHINE

natural evolution of code words and code language has been to some extent guided by regulations drawn up from time to time by international telegraph conferences.

The principal purpose of code in commerce is to effect economy, secrecy being usually of secondary importance (except in banking operations); in governmental affairs, however, the situation is exactly reversed. A code system is secret or nonsecret, depending upon the distribution and construction of the code book, and upon whether or not it is used in conjunction with a superimposed cipher system. Codes for general business correspondence are purchasable from their publishers and therefore provide in them-

frequency, such as QU in Spanish, or CH in German, afford clues leading to solution.

The basis upon which the solution of practically all substitution ciphers rests is the well-known fact that every written alphabetic language manifests a high degree of constancy in the relative frequencies with which its individual letters are employed. For example, English telegraphic text shows the following relative frequencies in 1,000 letters, based upon an actual count of 100,000 letters appearing in telegrams of a commercial and military nature.

| E | T | R | I | N | O | A | S | D | L | C | H | F |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|
| 126 | 90 | 83 | 76 | 76 | 74 | 72 | 58 | 40 | 36 | 33 | 33 | 30 |
| U | P | M | Y | G | W | V | B | X | K | Q | J | Z |
| 30 | 27 | 25 | 21 | 18 | 14 | 13 | 11 | 5 | 3 | 3 | 2 | 1 |

These characteristic relative frequencies serve as a basis for identifying the plain-text values of the cipher letters, but only when the cipher has been reduced to the simple terms of a single alphabet. Thus, the problem of solving a monoalphabetic substitution cipher involves only one step, since the text is already in the simplest possible terms, but the problem of solving a polyalphabetic substitution cipher involves three principal steps: first, determining the number of cipher alphabets involved; second, distributing the cipher letters to the respective monoalphabetic frequency tables to which they belong; third, analyzing each of the latter on the basis of normal frequencies in plain text. In the case of ciphers exhibiting periodicity, the cyclic phenomena are employed in determining the number of alphabets involved, as well as in distributing each cipher letter to the monoalphabetic frequency table to which it belongs. In the case of aperiodic ciphers, because of the absence of cyclic phenomena, both of these steps are often very difficult, especially when the volume of text is limited. Frequently the only recourse is to employ repetitions as a basis for superimposing separate messages so that, irrespective of the number of alphabets involved, or their sequence, the letters pertaining to identical cipher alphabets fall into the same columns, and then the separate columns are treated as monoalphabetic frequency tables. The analysis of the frequency distributions of a polyalphabetic cipher is effected much more readily when the alphabets are interrelated than when they are independent.

The question as to whether an absolutely unsolvable cipher system can be devised is of more interest to laymen than to professional cryptographers. Edgar Allan Poe's dictum that "it may be roundly asserted that human ingenuity cannot concoct a cipher which human ingenuity cannot resolve" is misleading unless qualified by restricting its application to the great majority of the practical systems employed for a voluminous, regular correspondence. For isolated, short cryptograms prepared by certain methods may resist solution indefinitely; and there is at least one cipher system which may be mathematically demonstrated as being absolutely unsolvable without the specific key, even though the basic method be completely known.

BIBLIOGRAPHY.—For history and references to the older works see under CRYPTOGRAPHY. Modern works are relatively few in number. The only ones in English are Parker Hitt, *Manual for the Solution of Military Ciphers* (1916); W. F. Friedman, *Elements of Cryptanalysis* (1924); and A. Langie, *Cryptography* (1922), the latter being a translation (by J. C. H. Macbeth) from the French version, *De la Cryptographie* (1918). A scholarly treatise on the origins of modern systems will be found in A. Meister, *Die Anfänge der moderne diplomatischen Geheimschrift* (1902) and in *Die Geheimschrift im Dienste der päpstlichen Curie von ihren Anfängen bis zum Ende des XVI. Jahrhunderts* (1906) by the same author. Detailed explanations and illustrations of modern methods will be found in A. Figl, *Systeme des Chiffrierens* (1926); M. Givierge, *Cours de Cryptographie* (1925); A. Lange et E.-A. Soudart, *Traité de Cryptographie* (1925); Dröscher, *Die Methoden der Geheimschriften* (1921); F. Delastelle, *Traité élémentaire de Cryptographie* (1902); E. Bazeries, *Les Chiffres secrets dévoilés* (1901); de Viaris, *L'art de chiffrer et de déchiffrer les dépêches secrètes* (1893); H. Josse, *La cryptographie et ses applications à l'art militaire* (1885); A. Kerckhoffs, *La cryptographie militaire* (1883); and F. W. Kasiski, *Die Geheimschriften und die Dechiffirkunst* (1863). Among a number of technical papers by W. F. Friedman the following are the most important: *The Index of Coincidence and its Applications in Cryptographic Analysis* (1922); *Several Machine Ciphers and Methods for their Solution* (1918); *Methods for the Solution of Running Key Ciphers* (1918). In justice to the many pub-

lishers of commercial telegraphic codes, no reference to any special ones can here be given, but any bookdealer can furnish a good list. For the history of codes see W. F. Friedman, *The History of the Use of Codes and Code Language, the International Telegraph Regulations pertaining thereto, and the bearing of this History on the Cortina Report* (1928). (W. F. F.)

CODEX, the name given to the earliest forms of manuscript (*q.v.*) in book form, *i.e.*, the collection of written pages stitched together which replaced the earlier *roll* of papyrus and the wax tablets (which when hinged or bound together formed the first *codex* or *caudex*); also the Latin form of the English word *code* (*q.v.*), meaning a body of law or regulations. For examples of famous codices, see the articles BIBLE, PALAEOGRAPHY, and LIBRARIES.

CODIAEUM, a small genus of plants belonging to the family Euphorbiaceae. One species, *C. variegatum*, a native of Polynesia, is cultivated in greenhouses, under the name of croton, for its variegated leaves. The six species are confined to Indomalaya, Polynesia and Australia.

CODICIL: see WILL.

CODINUS, GEORGE (GEORGIOS KODINOS), the reputed author of three extant works in Byzantine literature, two of which are anonymous in the mss. It is supposed that Codinus lived towards the end of the 15th century. The works referred to are:

(1) *Patria* (Τὰ Πάτρια τῆς Κωνσταντινουπόλεως). It is divided into five sections: (a) the foundation of Constantinople; (b) its topography; (c) its works of art and sights; (d) its buildings; (e) the construction of the church of St. Sophia. It was written in the reign of Basil II. (976-1025), revised under Alexius I. Comnenus (1081-1118), and perhaps copied by Codinus, whose name it bears in some (later) mss. The chief sources are: the *Patria* of Hesychius Illustrius of Miletus, an anonymous (*c.* 750) brief chronological record (*Παραστάσεις σύντομοι χρονικά*), and an anonymous account (*διήγησις*) of St. Sophia (ed. T. Preger in *Scriptores originum Constantinopolitanarum*, fasc. i., 1901, to be followed by the *Patria* of Codinus). (See also Procopius, *De Aedificiis* and the poem of Paulus Silentiarius on the dedication of St. Sophia.)

(2) *De Officiis*, a sketch of court and higher ecclesiastical dignities and ceremonies (*cf.* *De Cerimoniis* of Constantine Porphyrogenitus).

(3) A chronological outline of events from the beginning of the world to the taking of Constantinople by the Turks (called Agarenes in the ms. title). It is of little value.

BIBLIOGRAPHY.—Complete editions are (by I. Bekker) in the *Bonn Corpus scriptorum Hist. Byz.* (1839-43, where, however, some sections of the *Patria* are omitted), and in J. P. Migne, *Patrologia graeca*, clvii.; see also C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897).

CODLIN MOTH (*Cydia pomonella*), a small moth, the larva (caterpillar) of which is very destructive to apples and other fruit. Indigenous to Europe, it has spread, through the agency of commerce, wherever the apple is cultivated. The most effective methods of control are by sack-binding the tree trunks and by spraying with lead-arsenate. (See PESTS; ENTOMOLOGY, ECONOMIC.)

COD-LIVER OIL (*Oleum Morrhuae*, or *Oleum Jecoris Aselli*), the oil obtained from the liver of the common cod (*Gadus morrhua*). The usual process is to heat the fresh, cleaned livers by steam to a temperature above that of boiling water, or, by more recent practice, to a lower temperature, the livers being kept as far as possible from contact with air. The oils so obtained are termed "steamed-liver oils." The "pale" and "light brown" oils are used in pharmacy; the "brown" oil, the cod oil of commerce, being obtained from putrid and decomposing livers, has an objectionable taste and odour and is largely employed by tanners. By boiling the livers at a somewhat high temperature, "unracked" cod oil is obtained, containing much "stearine," which separates on cooling and is sold as "fish stearine" for soap-making, or as "fish-tallow" for currying. The oil when freed from the stearine is known as "racked oil." "Coast cod oil" is the commercial name for oil obtained from the livers of various kinds of fish; *e.g.*, hake, ling, haddock, etc. The chief centres of the cod-liver oil industry are Lofoten and Romsdal in Norway; the oil is also pre-

pared in the United States, Canada, Newfoundland, Iceland and Russia.

Cod-liver oil contains palmitin, stearin and other more complex glycerides; the "stearine" mentioned above, however, contains very little palmitin and stearin. Therapic and jecoleic acids have been identified and apparently do not occur elsewhere in the animal kingdom. Other constituents are cholesterol (0.46-1.32%), traces of calcium, magnesium, sodium, iodine, chlorine and bromine, and various aliphatic amines which are really secondary products.

Cod-liver oil is very readily absorbed from the skin and exerts all its therapeutic actions when thus exhibited. This method is often used for infants or young children with abdominal or other forms of tuberculosis. When taken by the mouth it is easily assimilable. It may cause nausea at first, but usually tolerance is soon established.

Cod-liver oil may be given in all wasting diseases, in tuberculosis and in rickets. It is occasionally valuable in chronic rheumatoid arthritis. Care must be taken to avoid the nausea, loss of appetite and diarrhoea, easily induced by this oil. It may be given in capsules, or as an emulsion, with or without malt-extract. The value of cod-liver oil depends partly on the food value of the oil itself, partly on the fat-soluble vitamin (*see* VITAMINS) and iodine it contains.

Cod-liver oil is used extensively in poultry feeds, either unmixed or combined with other oils, as a growth-accelerator for young chicks. It has proved especially valuable when their exposure to sunlight is restricted, making it commercially practicable to raise chicks in poorly lighted structures.

CODRINGTON, CHRISTOPHER (1668-1710), British soldier and colonial governor, whose father was captain-general of the Leeward Isles, was born in the island of Barbados, West Indies, in 1668. Educated at Christ Church, Oxford, he was elected a fellow of All Souls, and served later on with the British forces in Flanders, being rewarded in 1695 with a captaincy in the Guards. In 1697, he was appointed captain-general and commander-in-chief of the Leeward Isles. In 1703 he commanded the unsuccessful British expedition against Guadeloupe. After this he resigned his governorship and spent the rest of his life in retirement and study on his Barbados estates. He died on April 7, 1710, bequeathing these estates to the Society for the Propagation of the Gospel in Foreign Parts for the foundation of a college in Barbados. This college, known as the Codrington college, was built in 1714-42.

CODRINGTON, SIR EDWARD (1770-1851), British admiral, entered the navy in July 1783. He served on the American station, in the Mediterranean, and at home, till he was promoted lieutenant on May 28, 1783. Lord Howe selected him to be signal lieutenant on the flagship of the Channel fleet at the beginning of the revolutionary war with France. Codrington served with distinction throughout the war. From 1805 to 1808 he commanded the "Orion," which played a conspicuous part at Trafalgar, and was then transferred to the "Blake." In 1814 he was promoted rear-admiral, and acted as "captain of the fleet" to Sir Alexander Cochrane in the operations against Washington, Baltimore, and New Orleans. In 1815 he was made K.C.B., and was promoted vice-admiral on July 10, 1821.

In Dec. 1826 he was appointed to the Mediterranean command, and sailed on Feb. 1, 1827. On Oct. 20, 1827, in command of a combined British, French, and Russian fleet, he destroyed the Turkish and Egyptian naval forces at Navarino. As the battle had been unforeseen in England, and its result was unwelcome to the ministry of the day, Codrington was entangled in a correspondence to prove that he had not gone beyond his instructions, and he was recalled by a despatch dated June 4, 1828. After the battle Codrington went to Malta to refit his ships. He remained there till May 1828, when he sailed to join his French and Russian colleagues on the coast of the Morea. They endeavoured to enforce the evacuation of the peninsula by Ibrahim peacefully. The Pasha made diplomatic difficulties, and on July 25 the three admirals agreed that Codrington should go to Alexandria to obtain Ibrahim's recall by his father Mohammed Ali. Codrington

had heard on June 22 of his own supersession, but, as his successor had not arrived, he carried out the arrangement made on July 25, and his presence at Alexandria led to the treaty of Aug. 6, 1828, by which the evacuation of the Morea was settled. His services were recognized by a G.C.B. After his return home he was occupied for a time in defending himself and then in leisure abroad. He commanded a training squadron in the Channel in 1831, and became admiral on Jan. 10, 1837. From Nov. 1839 to Dec. 1842 he was commander-in-chief at Portsmouth. He died on April 28, 1851.

Sir Edward Codrington left two sons, Sir William (1804-1884), a soldier who commanded in the Crimea, and Sir John Henry (1808-1877), a naval officer, who died an admiral of the fleet.

See *Memoir of the Life of Admiral Sir Edward Codrington*, by his daughter Jane, Lady Bourchier (1873). This book contains much useful first hand criticism of the operations at L'Orient (1795) and at Trafalgar (1805).

CODRUS, in Greek legend, the last king of Athens. It was prophesied at the time of the Dorian invasion of Peloponnesus (c. 1068 B.C.) that only the death of their king at the enemy's hands could ensure victory to the Athenians. Devoting himself to his country, Codrus made his way disguised into the enemy's camp, and provoked a quarrel, in which he was killed. The Dorians, on discovering that Codrus had been slain, retreated, despairing of success. No one being thought worthy to succeed Codrus, the title of king was abolished, and that of archon (*q.v.*) substituted for it.

CODY, WILLIAM FREDERICK (1846-1917), American scout and showman, known under the name of "Buffalo Bill," was born in 1846 in Scott county, Iowa. He was a rider of the "Pony Express," a mail service established in the spring of 1860 by the Central Overland California and Pike's Peak Express Company to carry the mails overland from St. Joseph, Mo. to Sacramento, Calif., a distance of 1,950m., by means of relays of ponies, each rider being expected to cover about 75m. daily. When the "Pony Express" was discontinued in 1861, upon the completion of the Pacific Telegraph Company's line, young Cody became a scout and guide for the U.S. army. In 1863 he enlisted in the 7th Regiment of Kansas cavalry, in which he served until the close of the Civil War. In 1867 he made a contract with the Kansas Pacific railway to furnish its employees with buffalo meat while the line was being extended through the wilderness, whence arose the name "Buffalo Bill." In 1868-72 he was again an army scout and guide, serving against the Sioux and Cheyennes; and in 1872 was a member of the Nebraska house of representatives. During the Sioux-Cheyenne war of 1876 he served in the 5th U.S. cavalry, and at the battle of Indian Creek killed the Cheyenne chief, Yellow Hand, in single combat. In 1883 he organized his "Wild West Show," a spectacular performance on a large scale, his first European tour taking place in 1887. In the Nebraska national guard he again served against the Sioux in 1890-91. He died in Denver, Colo., on Jan. 10, 1917, and was buried in a tomb blasted from solid rock on Lookout mountain, 20m. from Denver.

COECILIA, a genus of limbless, worm-like amphibians (*see* AMPHIBIA), first described by Linnaeus as a group of snakes, but now recognized as of a distinct order of Amphibia to which the names apoda, peromela, and Gymnophiona have been given. The latter is now in general use by systematists, but the order is sometimes popularly called Coecilia.

The coecilians, or Gymnophiona, are all limbless, long-bodied Amphibia having a very short tail, the vent being nearly terminal. Their bodies are usually more or less ringed by a series of dermal folds which give their owners the appearance of large earthworms. Within these folds there are found in most genera a series of minute scales which distinguish the Gymnophiona from other Amphibia. All genera are characterized by a peculiar protrusible tentacle on the side of the face near the nostril or eye. It is said to function as a tactile organ, but is radically different from such sense organs in other Amphibia. Coecilians are primitive forms apparently directly derived from the extinct lepospondylia. They

show no close affinity to other living groups, and are more primitive than other living Amphibia in possessing in certain genera a post-frontal (*Ichthyophis*, etc.), an ectopterygoid (*Hypogeophis*, etc.), a transitory spiracle cleft, a sixth gill sack, four pairs of functional thymus glands and two additional pairs of rudiments during development. Such apparently primitive structures as the unspecialized hyoid apparatus may owe their simplicity to secondary degeneration. In certain features of the skull the coecilians resemble a partly metamorphosed urodele, such as *Cryptobranchus*, but one highly modified for burrowing. The lidless eyes are usually indistinct and sometimes very degenerate and hidden under the bones of the skull. In spite of primitive characters of integument and skull the coecilians must be considered a highly aberrant and specialized group.

Nieden (1913), the latest reviewer of the order, recognizes nineteen genera and fifty-five species, all referable to a single family, the Coeciliidae. The primitive genera *Ichthyophis*, *Rhinatrema*, etc., possess scales, exhibit the fewest fusions of skull elements, and are the least modified for burrowing. The most specialized are either degenerate burrowers or aquatic (*Typhlonectes*). In correlation with the habitat the structure of integument, skeleton, or lungs may be modified. The coecilians inhabit the tropics. They are seldom seen except after heavy rains or after ploughing the ground.

The life histories of several genera of coecilians are known. *Ichthyophis* lays its eggs on land in damp situations, the larvae escaping to take up an aquatic existence. The more specialized *Hypogeophis* skips over the larval stage. Finally the aquatic *Typhlonectes* retains its eggs within the oviduct and gives birth to living young. Other species may be oviparous, others viviparous.

(G. K. N.)

COEDUCATION is the education of both sexes in the same classes in an institution. This term has been given several interpretations, the most extreme of which is that girls and boys "shall be taught the same things, at the same time, in the same place, by the same faculty, with the same methods, and under the same regimen." This is based upon the assumption that there are no differences between girls and boys and consequently they should be given precisely the same education. The more accepted interpretation is that there are differences in their physical and mental powers and needs, but that because of their fundamental similarities they should be educated together, uniting in many classes, in many sports, and in much of their social life, but modifying all these to suit their special differences.

Coeducation as a definite educational method or policy is modern and comparatively recent in its adoption. The constitution of society in the early centuries, with war and religion—which engendered belligerency—as the chief occupations and interests, confined education to men and boys. As far back as the first century Greece had schools for boys. France and Germany established them in the fourth century and England has a record of a similar school in 598. Private education for boys of certain classes was possible long before this both in Europe and the Orient. More than a thousand years passed before education of girls was attempted on any scale whatever. What education girls had received had been secured either privately or in convents or a few segregated schools, and such opportunities were confined almost entirely to families of wealth. In a few instances girls—princesses or members of the aristocracy—had been taught with their brothers at home, or occasionally a young woman had been permitted to attend a few lectures with her brothers. Although several of the teachers of ancient and mediaeval days advocated ultimately teaching girls, and even the sexes together, it remained a theory except in such special cases.

As long as the idea prevailed that women were designed to be "decorative, pleasant toys for man's amusement," or that "edu-

cation would render them less useful and agreeable to men," very little education except with these objects in view could be obtained. With changing social, economic and religious conditions, the status of woman changed. Since educational opportunities were so firmly established for boys in all countries existing through ancient and mediaeval days, education for girls became a question of method. With few exceptions, at first segregated schools were provided. Then as a matter of economy girls were admitted to some boys' schools, or small schools were established for both together, usually elementary in character. In Scotland coeducation in the elementary schools was established as a definite policy in the late 17th century, though boys and girls had attended the same parish schools together previous to this.

An innovation in matters of education was promulgated by the Massachusetts colony in the New World when it passed laws in 1642 and 1647 providing for free compulsory education for all its children, this being almost as soon as the colony was settled and this being also the basis upon which all education in the colonies and the United States has since been developed.

In the 19th century women began to demand an education equal to that of their brothers. As they edged or fought their way into various institutions the question of coeducation—its efficacy and desirability—became a widely debated subject, especially in the Old World countries where tradition and custom have held through many centuries and where changes of a radical nature are made slowly. As yet coeducation is not popular there though it has been adopted in a number of countries for the earlier grades where the Government has assumed the responsibility of giving free education to its children.

England.—Coeducation was tried in England as an experiment in a number of private schools established either by individuals or societies in the middle of the 19th century. Free elementary schools, coeducational in character, were established as a result of the Education Acts of 1870 and 1902, but they have never found favour with the "classes," and are attended almost entirely by the "masses." In the '70s, when the desire for higher education spread among women, the two colleges for women, Girton and Newnham (1874), did not give what was wanted. Then began the long struggle, led by the Headmistresses' Association, to secure entrance to and degrees from the universities of England, especially Oxford and Cambridge, which has been fully accomplished only recently.

France.—Compulsory education was established in France in the early 19th century, but since 1867 each commune with population of over 500 has been obliged to support a separate school for girls. While there are some 20,000 mixed schools in France, these are attended almost exclusively by children of the middle and artisan classes. Segregation above the 13th year is almost the invariable rule. A number of universities, established exclusively for men, have admitted women and to that extent they are coeducational.

Germany.—With the adoption of compulsory elementary education in Germany, mixed or coeducational schools developed in the smaller cities, and about two-thirds of the children are now educated in this manner. Since the overthrow of the Monarchy changes in educational matters as well as social and political are taking place. Higher education is much in demand by German women and while no coeducational universities have been established since the World War, many old universities are admitting women.

The Orient.—In the East women as a whole have hardly started on the road to education of any kind. Thousands of years of tradition, the great diversity of religions and the texture of society have all been responsible for the slow progress of their education. In China, Roman Catholic and American Protestant missionaries in the middle of the 19th century established mission schools which started the movement for the education of girls. As yet schools are not numerous and coeducation is practically non-existent.

Japan, which established its first school for boys in 794 A.D., paid little heed to the education of girls until the last half century. Affected by the overthrow of the feudal system, and by the

results of the study of educational systems in the United States and Europe, the Japanese Government adopted (about 1871) free, compulsory, secular education for boys and girls in a common school. Segregated high schools are provided for children over 12. Japanese women have been greatly influenced by contact with the women of the United States where many go for study, and are requesting more opportunities in their own country. In increasing numbers, they are attending the Imperial universities (opened to them in 1920) and the free universities which have followed this example.

India.—The factors involved in India's problem of education are numerous and most complicated—antagonistic religions, the caste system, the child brides and child widows, the economic situation, lack of efficient teachers, apathy of adults—these make a seemingly almost hopeless array. In 1928 1% of the girls were literate and only 1.03% were under instruction. Coeducation is confined to the village schools for an economic reason, but separate schools for girls are being established as soon as the village can do so. Less than a thousand women are studying in girls' colleges, a few hundred in men's colleges and technical schools. There is little interest in education for girls and practically none in coeducation though prejudice toward both is slowly lessening.

Italy.—Italy has made great changes since the World War in its educational policy for women. Many women were forced into men's occupations and as they realized the need for more preliminary training the situation was met at first by permitting them to go to the liceo, or higher school for boys. As the numbers increased Italy had neither time nor money to build separate schools. Consequently coeducation exists in the higher schools established for boys, leading to the universities—many of which are now open to women.

South America.—The varying political and economic changes in South American countries, the difficulties of communication between countries and parts of the same country, the immense distances, small population, the topography and the general apathy or hostility toward education of women have all contributed to its slow progress. Though coeducation exists to a limited extent in some South American countries, it is neither popular with nor patronized by those who can afford to send their daughters to convents or church schools. Argentina has made the greatest progress, dating from 1868, when North American methods and teachers were introduced by the president. About half the schools are now coeducational. Brazil, 3% of whose population attend school, has, since the establishment of the republic in 1889, set up free, primary, secular schools, a few of which are coeducational—though they serve mostly as models. Sixteen-sevenths of the population are Roman Catholics which makes separation of Church and State difficult. Chile has admitted women to its teacher training schools since 1890, at first with reluctance and some reservations. Latin American universities which form a chain from the University of Mexico (1551) to southern Argentina were established for religious purposes for men. Their character has been somewhat modified and women are now admitted to many such universities.

United States.—Coeducation is a distinctive feature of education in the United States and extends from the kindergarten through the college. It probably originated in colonial days in New England before the advent of public schools when boys and occasionally girls with them were instructed in the Dames' schools and later in private schools as a matter of expediency or necessity.

Coeducation received a great impetus following each of the three great wars of the United States. The Revolutionary War brought new ideas, stabilizing the new government and the quiescent development of a new country. The Civil War opened up and widely extended the profession of teaching for women. The World War brought tremendous changes in the economic, political and social status of women, and opened hundreds of occupations previously closed to them.

Owing to a difference in type and purpose of the early settlers of New England and of the more southern colonies, a difference in their attitude toward education developed, and these differences appeared in the new settlements opened by migrants farther West.

The colonial South because of its early indifference, because of its greater economic freedom and because of its institution of slavery, developed public education and coeducation more slowly. The New England idea of coeducation was transplanted throughout the Middle West and Northwest, and gradually this type has been adopted throughout the country, due also to economic conditions, sparsely settled country, lack of transportation, growing ideas of democracy and the women's rights movement. Coeducation is the accepted and predominate mode of education in about 97% of the public elementary and secondary schools of the United States, students in 258,859 such schools in 1926 numbering 24,741,468.

The establishment of coeducational colleges and universities by private endowment, by Churches and by States has been remarkably rapid west of New York State. The East has been slow to adopt coeducation, largely owing to the age and prestige of its men's colleges, these having been founded when the colonies were young; and to the prestige of the women's colleges opened to meet an unfulfilled demand of eastern women for college training. St. Lawrence university was chartered in 1861 as a coeducational institution and was followed by Cornell in 1868 and Swarthmore in 1869, these being the first in the East. Others followed rapidly, Syracuse (1870), Boston (1873), and then a few institutions, exclusively men's for forty to one hundred years, began to admit women, notably Vermont (1871), Maine (1872), Pittsburgh (1874), Pennsylvania (1877), etc.

Collegiate coeducation began much earlier in the Middle West and Northwest. Oberlin opened as an academy in 1833 and in the same year what is now Kalamazoo college was chartered. In the '40s such coeducational institutions as Buffalo, Earlham, Grinnell, Eureka, Iowa Wesleyan, Lawrence, Mt. Union, Otterbein, Pacific and Williamette were founded; and Knox and Albion admitted women. The '50s saw the first coeducational State universities established, Utah in 1850 and Iowa in 1855, and the formation of numerous Middle West coeducational colleges continued. During the '60s seven more State universities were chartered as coeducational, and Indiana, Minnesota and Missouri admitted women. All but five states have coeducational universities, two only partially. Four of the five have no State universities. The universality of coeducation west of the Mississippi is made apparent by the fact that in all this territory there are but four women's colleges, one established in 1927. In this same territory almost without exception the leading institutions are the State universities. Practically every department of collegiate instruction is open to women,—professional courses as well as liberal arts, and many institutions are admitting graduate women whose undergraduates are entirely men.

Experience is the only method of testing the results of coeducation and with the fourth generation of coeducationally trained women now in colleges in the United States, the old objections there have been refuted.

Other Countries.—A coeducational system is being built up in Canada similar to and influenced by that of the United States since intercommunication is easy and their economic problems and types of settlers are similar.

Denmark has developed its coeducation largely through the cooperation of several families in the matter of establishing schools. This custom and the later establishment of free schools for boys and girls have led to its public school system. The other Scandinavian countries, and Holland, Belgium and Switzerland, have all developed coeducation to a certain degree in the public school system.

Summary.—The old arguments against coeducation—that it will effeminate the men and coarsen the women, that the women have not sufficient health, strength or mental ability for higher education or to compete with the men—have been repeatedly disproved. The remaining objection seems to be largely a matter of centuries of custom, of racial differences and class prejudice. Tradition and prejudice still favour the segregated schools where possible.

The numerous changes in the character of government in the past 50 years have greatly affected educational policies, and

definite conclusions are not yet reached as to the best methods—coeducation or segregation. With the development of mental hygiene and psychology some educators are again speculating whether it might not be advisable to separate the sexes, at least during a few years of adolescent life, especially as there seems to be a natural segregation in some fields because of the increase of vocational and professional courses adapted to the different sexes. In the United States and Canada the tendency continues to be toward coeducation in all schools, working out individual interests because of sex differences in coeducational public schools rather than in private segregated schools. Nowhere in the world is coeducation developed to the extent and with the democratic spirit that exists in the United States. (R. L. F.)

COEFFICIENT, a term used in algebra originally to represent either of the two rational factors of a monomial. For example, in its primitive meaning, in the expression ab either a or b would be the coefficient of the other, the two acting together with the same efficiency. The meaning of the word has, however, been gradually enlarged as algebra has developed. At present a coefficient is generally considered as a number or other known factor written before an algebraic expression. For example, in the expression $2ax^2$, $2a$ is the coefficient of x^2 , but 2 is also considered as the coefficient of ax^2 . Similarly, in the case of $\frac{1}{2}xy$, the coefficient of xy is $\frac{1}{2}$, and in the expression $\frac{1}{2}a\sqrt{3}(x-y)$, $\frac{1}{2}a\sqrt{3}$ is the coefficient of $x-y$. The term was introduced into algebra by Vieta (Viète), at the close of the 16th century. In algebra it is often required to perform some such operation as the division of $x^4-7x^3+19x^2-22x+3$ by $x-3$. This is conveniently done by using *detached coefficients*, simply dividing $1-7+19-22+3$ by $1-3$, using the ordinary arrangement of work, or that of synthetic division as explained in textbooks. This saves the labour of frequently writing the letters during the operation. (See ALGEBRA; POLYNOMIAL EQUATIONS, THEORY OF.)

COEHOORN, MENNO, BARON VAN (1641-1704), Dutch soldier and military engineer, of Swedish extraction, was born at Leeuwarden in Friesland, and became a captain in the Dutch army. In 1673 he took part in the defence of Maastricht and in the siege of Grave, where the small mortars (called coehorns) he invented troubled the French garrison. He was made a colonel for his conduct at the battle of Seneff (1674), and was also at the battles of Cassel (1677) and Saint Denis (1678). He was an innovator in fortification, and his first published work, *Versterckinge de Vijfhoek met alle syne Buytenwerken* (Leeuwarden, 1682) caused a controversy with Louys Paan (Leeuwarden, 1682, 1683); Coehoorn was entrusted with the reconstruction of several fortresses in the Netherlands, and became the worthy rival of his great contemporary Vauban. In his chief work, *Nieuwe Vestingbouw op en natte of lage horizont*, etc. (Leeuwarden, 1685), he laid down three "systems," the feature of which was the multiplicity and great saliency of the works, eminently suited for flat sites such as those of the Low Countries. He borrowed many details from his Dutch predecessor Freytag, or from Albrecht Dürer, and Speckle, and studied the individual case, not theoretical perfection; e.g., at Groningen.

From 1688 to 1697 Coehoorn was a brigadier. At Fleurus he distinguished himself. In 1692 he lost Namur, a fortress of his own, to Vauban, but retook it in 1695. Coehoorn became lieutenant-general and inspector-general of the Netherlands fortresses, and the high-German peoples as well as the Dutch honoured him. He commanded a corps in Marlborough's army from 1701 to 1703, and in the constant siege warfare his skill was of the highest value. The swift reduction of Bonn and the siege of Huy in 1703 were his crowning successes. He died of apoplexy at Wijckel on March 17, 1704.

His "first system" was applied to Nijmegen, Breda, Bergen-

op-Zoom, and Mannheim, his second to Belgrade and Temesvá among other places. His son, Gosewijn Theodor van Coehoorn wrote his life (re-edited Syperstein, Leeuwarden, 1860). His *Nieuwe Vestingbouw* was translated into English by T. Saverj (1705); see also the article FORTIFICATION AND SIEGECRAFT and the bibliographies under that heading.

COELENTERATA (sē-lēn-tur-ā'tā). The term Coelenterata is applied to a large group or phylum of animals of a lowly grade of organization. Only two types of animals possess a more simple structure than the Coelenterata; viz., the sponges and the Protozoa. The Protozoa are organisms whose body usually consists entirely of a single cell, which is generally of microscopic size. In certain instances a number of these cells become banded together to form a colony, but in such a case they are not arranged so as to constitute tissues, and are individually autonomous and self-supporting. In the case of the sponges we are dealing with animals consisting of a multitude of cells of different kinds which are massed together, and many of which are segregated into definite sheets or tissues, each sheet performing a function or functions of its own. A sponge develops from a definite embryo which is the outcome of the cleavage of a fertilized egg, but apart from this it is very unlike the animals of the higher groups in that it constitutes in its adult condition a fixed plant-like object often of somewhat indefinite shape. The sponges probably represent a series of products of evolution which diverged from protozoan ancestors in a direction distinct from that pursued by any other animals and which led on to nothing beyond the sponges themselves. The Coelenterata, however, from beginnings similar to those of the sponges, achieved an altogether higher grade of organization, producing not only tissues but also a much more definite form and individuality than the sponges, involving the differentiation of nervous and muscular systems and consequently efficient co-ordination of parts and considerable powers of movement and locomotion. In the sponges primitive muscular tissue exists locally, but there is no nervous system.

Structure of a Coelenterate.—The body of a Coelenterate resembles in architectural principle that stage which may be recognized in the early development of so many animals above the degree of sponges, and which is known as *gastrula* (fig. 5). A gastrula consists of a small sac, with a single opening at one end of it (the *blastopore*). The walls of the sac possess two layers of cells, one passing into the other at the margin of the blastopore. The inner layer is known as endoderm, the outer as ectoderm. No Coelenterate, however complex may be its structure, passes beyond the fundamental plan thus outlined; though its size may be great and its parts elaborate, it remains an animal possessing one principal internal cavity only, the *coelenteron*, which opens to the exterior by a single main aperture, the mouth. In a typical higher animal the body contains two principal cavities, the food canal, and another main cavity situated between the wall of the food canal and the outer integuments of the body. In such a form the food canal opens to the exterior by a second aperture (the anus) through which the undigested material is voided; the Coelenterata possess no such opening and waste substances are ejected through the mouth.

There is, in fact, no existing Coelenterate in which the adult animal is quite as simple as a gastrula; but there do exist creatures in which the main differences are that the cells of the ectoderm exhibit a differentiation into more than one kind, and that there lies between ectoderm and endoderm a thin sheet of non-cellular material, the *mesogloea*, which supports the other layers. An example of such a grade of structure may be found in *Protokhydra*.

The majority of Coelenterata, however, develop a complexity far exceeding this. The actual form of the body varies almost infinitely, but usually a prominent feature of the organization is the presence of a number of tentacles placed in a definite manner around the mouth. These tentacles may be solid structures, containing a core of endoderm and a covering of ectoderm, or they may be hollow, the wall in such case including both cell-layers. The symmetry of the body is usually characterized by the fact that the various parts are arranged about the radii of a circle with

the mouth as its centre, and that the same structures are repeated in a regular manner in different sectors. In other words, the animal is radially symmetrical and can be divided by suitable radial cuts into a varying number of parts each of which is exactly equivalent to the others. This symmetry is not invariably present, but is extremely prevalent, although in one section of Coelenterata (the Anthozoa) it is accompanied by an underlying bilateral symmetry which mars its perfection. The middle layer or mesogloea varies greatly in bulk in different cases, being sometimes extremely tenuous and small in amount, sometimes very extensive and forming the greater part of the mass of the organism.

Polyp and Medusa.—The Coelenterata exhibit two main types of shape, both founded upon the gastrula plan.

1. *The Polyp.* The name *polyp* (figs. 1 and 2) is derived from the French *poulpe*, a term applied to an octopus. There is no actual relationship whatever between a Coelenterate polyp and an octopus, the comparison having been suggested by the fact that both of them possess mobile tentacles. A good example of a polyp is a sea anemone, the essentials of its structure being a hollow cylindrical body closed in below by an adherent disc-like base, above by another disc (the *peristome*) bearing the mouth in its centre and a circlet of tentacles round its outer part. Details of the structure of different kinds of polyps are given in the articles HYDROZOA, ANTHOZOA and SCYPHOZOA.

2. *The Medusa.* Those Coelenterates popularly known as "jelly-fish" are scientifically christened medusae, the name referring to the resemblance borne by the long mobile tentacles of some of these animals to the writhing, snaky tresses of the Gorgon Medusa. The body of a medusa (fig. 3) is shaped like an umbrella, and hanging down inside it from the point at which the handle of the umbrella would be attached, is a structure known as the *manubrium*, at the end of which is the mouth. In this case the tentacles form a circlet round the margin of the umbrella. For details of the organization of Coelenterate medusae reference should be made to the articles HYDROZOA and SCYPHOZOA.

Alternation of Generations.—One of the most interesting features connected with the Coelenterata is the fact that a single animal may for part of its life be a polyp and for part a medusa; or from a polyp, buds may be formed which develop into medusae. In cases such as the latter it is the polyp which is developed from an egg, and this polyp itself produces no sex-organs; it is able however to give origin to vegetative buds which develop into medusae, and these in their turn bring forth sex-cells which after fertilization initiate further polyps. In this way there is regular alternation between polyp and medusa and the phenomenon is termed *metagenesis* or alternation of generations.

Polymorphism and the Formation of Colonies.—Another marked characteristic of the Coelenterata is their tendency to form colonies of individuals united to each other by a common stem,

plate or mass of intermediate tissue. The colonies so formed are generally attached permanently to foreign surfaces, but in some cases they form strings or aggregations of individuals which float or are propelled through the sea. Coelenterate colonies are frequently characterized moreover by the production in one and the same colony of different kinds of individuals, among which the various functions are distributed. There may co-exist in a single colony not only polyps as well as medusae (fig. 4), but more than one kind of each of these types of individuals. There may be sexual medusae and medusae transformed into locomotory organs; polyps whose main function is digestion and others which catch and paralyse prey; and so forth. The phenomenon thus outlined is known as *polymorphism* and *metagenesis* is a form of it; it is one of the most interesting manifestations of the diversity of animal life, and is considered in more detail at the end of the article HYDROZOA.

Development.—The Coelenterata pass during the course of their life-history through a series of stages very unlike the adult animal. A simple instance of these stages is provided by the embryology of the common sea anemone, *Metridium senile* (fig. 5). In this species the eggs are shed into the sea by the parent and are there fertilized. After fertilization the egg divides into halves and each of these once more into two. The four cells (or *blastomeres*) so formed are equal or sub-equal in size. This process of subdivision is continued until a considerable number of small cells have been formed, and these are so arranged as to constitute a hollow sphere containing fluid. The sphere is known as a *blastula* and the cavity as a *blastocoele*. The blastula continues to develop in such a way that one side of the sphere first

flattens and then becomes concave, being finally completely invaginated into the other half. This process practically obliterates the blastocoele, and forms in its stead a second internal cavity, the *archenteron*, which communicates with the exterior by means of a small opening, the *blastopore*. There has thus been produced a typical gastrula such as has been previously described; its archenteron becomes directly transformed into the coelenteron of the

adult, and the blastopore becomes the adult mouth. During its early stages the animal moves through the water by the aid of cilia which appear on its outer surface during the blastula stage, but before it begins to assume the adult shape it tends to remain at the bottom, moving horizontally and resting from time to time, and often becoming temporarily attached to the bottom mouth downwards, during which time it may execute slow creeping movements. From this larva the adult anemone-polyp is achieved by degrees. At a given time the larva settles down and attaches itself to a foreign surface; its proportions change, it acquires tentacles, and becomes a small polyp.

The embryology of the Coelenterata varies considerably from one species to another, but generally speaking it is characterized by the presence of a gastrula-stage or of some equivalent. Frequently no actual gastrula exists but instead a corresponding stage known as *planula* is produced, in which there is no blastopore, the embryo consisting either of a hollow two-layered organism or of a central mass of endoderm-cells covered externally by a layer of ectoderm (fig. 5). Planulae and gastrulae may be free-swimming organisms moving by means of cilia, or may be contained within the coelenteron of the parent or within a protective enclosure so that they have no actual free existence, and are born as young polyps.

Motion.—The movements of which a Coelenterate is capable depend upon its shape, organization and mode of life. A jellyfish is an active free-swimming creature which progresses through the water as a result of rhythmic or spasmodic contractions of its bell-like body brought about by the action of muscles. Different kinds of jellyfish are active in varying degrees; some are much stronger swimmers than others, some are decidedly sluggish, whilst a few are creepers. Movement in polyps varies according to whether they possess a skeleton or not; in those provided with such a structure movement is naturally limited to those actions which the tentacles or other parts of the polyp can perform unrestricted by the hard parts. If a polyp is free from skeleton, it can move in a variety of ways; rarely, it swims actively by concerted lashing movements of the tentacles; sometimes it will creep on these organs; or it may attach itself by the base, bend over and attach the tentacles, then loosen the base, move its body and re-attach the base elsewhere. On the other hand it may simply loosen its hold and allow the motion of the water to carry it elsewhere, and in such case may inflate itself with water in order to become more buoyant; or it may creep upon its base, a method characteristic of many of the large polyps of the sea anemones.

The movements exhibited, apart from those connected with actual locomotion, consist of contractions and expansions of the tentacles and body, movements of the mouth, and so forth, connected with capture and swallowing of food, with retraction for the purpose of sheltering from adverse conditions, and with similar matters. Tentacles are usually highly contractile, and in their most concentrated condition are very much smaller than when expanded. The whole body may be relatively rigid and not, as a whole, very contractile, in forms possessing a high development of the mesogloea; but in many cases it is as contractile as the tentacles and may be reduced at need to a bulk very much smaller than its size when expanded; e.g., to an eighth of its maximum bulk.

Muscles.—Although the general substance of a Coelenterate is contractile, the definite movements which it performs are the result of muscular or ciliary action. The muscular system in its simplest condition consists of a single layer or sheet of muscle-fibres, lying on the inner or outer surface of the mesogloea. The muscle-sheets of Coelenterates are normally only one fibre thick, and each fibre lies directly upon a supporting surface of mesogloea. Consequently if strong localized muscles (as distinct from diffuse sheets) are required, these are generally attained by the simple expedient of pleating the surface of the mesogloea into ridges, on the surface of which lie the fibres, still in a single layer. In certain cases muscle becomes embedded in the mesogloea. The individual fibres are not in the simpler instances independent structures, but belong to and form part of epithelial cells of the ectoderm or endoderm. Thus the combination of each cell with its

"muscle tail" (or tails) constitutes a musculo-epithelial cell, a structure characteristic of Coelenterata but rare among higher animals (fig. 8). In more specialized cases the muscle-fibres of the ectoderm become separate structures, the epithelial cells which produced them being of insignificant proportions.

The Finer Structure of the Tissues.—The structure of the layers of the body must now receive short notice (fig. 6). The

mesogloea is a sheet of very variable structure; sometimes it is gelatinous in texture, sometimes almost cartilaginous, or again it may be very watery and unsubstantial. It contains within its substance cells which have wandered there from the other layers, and the functions of which are not fully understood. Some of them at least are amoeboid cells which carry or transmit nutriment from the endoderm (the digestive layer) to other parts of the body. Others probably add to the mesogloea substance by secretion, whilst it is possible that some of them constitute part of a mesogloea nervous system. At its highest development the mesogloea possesses fibres as well as cells, but these are not at all of the same nature as the muscular fibres. The cell-layers are best considered separately, and the following details apply to a sea anemone, which will serve as a suitable example. The ectoderm is an epithelium consisting of elongated supporting cells which are ciliated in some parts of the body, and among these occur large numbers of cells of other kinds. There are glandular cells which secrete mucus, etc., sensory cells which constitute the peripheral receptive elements of the nervous system, cnidoblasts which secrete curious explosive capsules about which more will be related shortly, and undifferentiated interstitial cells which may give rise to other kinds at need. In the deeper parts of the epithelium lie nerve cells (the nervous system is further described below) and on the surface of the mesogloea, in given parts of the body, are the muscle fibres, which are here independent of the supporting cells. The endoderm resembles the ectoderm in general constitution, but its supporting cells, instead of being ciliated, bear each a single large cilium or flagellum, and each possesses a basal muscle fibre, and so constitutes an epithelio-muscular cell. Many of them are digestive in function. Gland-cells are to be found in the endoderm, as also are sensory, nervous and interstitial cells; cnidoblasts are most characteristic of the ectoderm; but also occur freely in the endoderm where necessary.

The germ cells of the Coelenterata, those cells which will due course form eggs or spermatozoa, are formed sometimes f

interstitial cells, sometimes from differentiated epithelial cells. They may originate in either ectoderm or endoderm, but are not necessarily first formed in the region in which they will ripen.

General Functions.—The Coelenterata possess no special organs for respiration or excretion, and possess neither blood nor blood-vessels. Respiration and excretion are performed by the general surfaces of the body, but sometimes the chief excretory areas are localized. Circulation in the true sense does not exist, although currents are produced in the fluid contained in the coelenteron by means of the endodermal flagella. The distribution of substances through the tissues takes place partly through the agency of amoeboid cells and partly by diffusion. Feeding and digestion must be more closely considered.

Capture of Food.—The Coelenterata are generally speaking carnivorous, and capture food by two principal methods. The commonest way is to seize the prey with one or more of the tentacles, to convey it to the mouth and swallow it. This is made possible by the fact that the tentacles possess stinging and adhesive powers of a high order. A tentacle will adhere to and will paralyze or kill any organism which is desired for food, provided that the prey in question is not too large or too tough to be penetrated by the poisonous threads shot out by the tentacle. These threads are shot forth in countless numbers from the tentacle-surface, each being everted by one of those explosive capsules which have been mentioned above. Although microscopic in size, the threads have astonishing powers of penetration, and the poison which they carry with them, although weak in some Coelenterates, is usually strong enough to paralyze the prey suitable to each species. In the case of the most powerful stingers the poison is extremely virulent, and contact with a tentacle will produce violent pain in the human skin. The fact that the threads penetrate enables the tentacle to adhere to the prey unless its struggles are strong enough either to break them or to pull away part of the ectoderm, and in some cases there exist, in addition to the capsules with penetrating threads, others whose threads do not enter the prey but are covered with sticky material and adhere to it. The prey captured by this method is transferred by the tentacles to the mouth, which is generally very extensible and can open widely so as to engulf objects which in some cases are enormous in relation to the size of the swallower. The Coelenterate has not necessarily finished stinging the prey after it has been taken in, for in many cases there exist internal stinging organs.

There is another method of feeding which may supplement or replace the characteristic one. Small food-particles which come in contact with some part of a Coelenterate become entangled in slime secreted by that part, and these are transported by means of cilia acting in definite directions to the mouth. This method of feeding is probably the predominating one—for instance, in certain sea anemones—and a good example of its working may be seen in the jellyfish *Aurelia*. (See article SCYPHOZOA for an illustration.) When *Aurelia* is feeding, planktonic organisms become entangled in strings of slime on the outside of the swimming-bell, and are conveyed by the movements of the bell aided by the action of cilia to the edge of the umbrella. Arrived at this point they are concentrated into eight masses at points situated at regular intervals round the margin of the bell. From time to time these masses are licked off by one or other of the four large arm-like processes which hang down under the bell round the mouth; and since each of these arms contains a groove leading directly into the mouth, the food-mass is from this point onwards easily transported into the stomach. The underside of the swimming-bell also contributes to the eight food-masses and the oral arms themselves collect plankton independently. This seems to be a normal mode of feeding in *Aurelia*, but at the same time it can and does, at any rate when young, catch fishes and other organisms as well as plankton.

The Food of Coelenterata.—The food of Coelenterates includes a great variety of animals—fishes and their eggs, crabs and all manner of other crustacea, worms, molluscs, other Coelenterates, etc., not to mention the innumerable small planktonic organisms imbibed. Some Coelenterata are omnivorous, but others again will select their food more or less definitely. Certain special

forms feed upon unicellular Algae (*Zooxanthellae*).

Digestion.—Digestion in Coelenterates is a process involving two stages. If a large object has been swallowed it is first broken up into particles and the latter are then engulfed or ingested by individual endoderm cells within which each particle becomes surrounded by a fluid-containing vacuole and there the remaining processes of digestion and absorption take place. Thus the whole process involves first *extra-cellular* digestion in the coelenteron, and then *intra-cellular* digestion in the endoderm; or if the food is small enough it may be directly ingested by endoderm-cells without previous breaking down. The details of this process vary according to the anatomy of the Coelenterate in question. In a simple case such as that of *Hydra*, the coelenteron is lined by a simple and fairly uniform layer of endoderm, not concentrated into special structures; and in such case this layer performs the double function of secreting digestive material which will break up a large prey and of ingesting the fragments so produced. In a higher form such as a sea anemone or coral the endoderm is differentiated into regions; there are definite tracts of epithelium in which gland-cells are concentrated, and these constitute together with the adjacent endoderm the main digestive area. These tracts, the mesenterial filaments, have been shown to secrete a digestive juice; and although they may also themselves ingest, in the most specialized cases the main absorptive region is not the filament itself but the endoderm on either side of it. The area of endoderm which will ingest food in such cases varies according to the size of the meal. The digestive ferments of Coelenterates are generally speaking specialized for dealing with animal prey.

Nervous System.—This is of a very primitive grade in Coelenterata, and possesses neither actual nerves nor any central controlling organ. Its essential parts are the sensory cells of the ectoderm and endoderm, together with a network of fine fibrils connecting those cells with the muscle fibres and with nerve cells. The cells and fibrils constitute a "nerve net" which runs in the deeper part of the epithelium (fig. 7) and perhaps also penetrates the mesogloea. The net is sometimes fairly evenly distributed, sometimes better developed in one part than in another, and sometimes decidedly concentrated in given regions. Its action is especially characterized by the fact that it confers autonomy upon given parts of its possessor, so that these will function in the absence of the remainder (e.g., the basal half of a horizontally divided sea anemone will execute creeping movements in the absence of the head-end) and by the further fact that an impulse is believed to travel in any direction through the net, this con-

trasting markedly with the one-way transmission to which a more highly organized nervous system is restricted. This has been demonstrated experimentally by making elaborate preparations from the umbrella of living jellyfish in such a way as to restrict the nerve net to figures of given shape. So long as organic continuity from point to point is maintained in any given figure an impulse started at any point will spread throughout the system. In certain Coelenterata the nerve net exhibits locally signs of a higher differentiation than this.

Many Coelenterata possess definite sense-organs. These are naturally found in the more active members of the group, that is to say the medusae; they are absent altogether in the polyps. The chief

FROM SCHNEIDER, "LEHRBUCH DER VERGLEICHENDEN HISTOLOGIE DER TIERE" (FISCHER)

FIG. 7.—PART OF THE NERVE NET OF A COELENTERATE

types of sense-organ are two in number, and these are described in connection with the animals possessing them, in the articles HYDROZOA and SCYPHOZOA. The first type includes organs sensitive to light and termed *ocelli*; and these structures, though often simple, may attain at their highest development the grade of eyes (see *Charybdaea*, in SCYPHOZOA). The second type comprises organs of variable structure (*statocysts* and *tentaculocysts*) which include hard particles (*statoliths*) in their constitution, and whose function is not yet fully understood. Although they might

be expected to be organs of balance this does not appear to be actually the case. It has been ascertained experimentally however, that certain of these organs initiate the stimuli which produce the swimming-contractions of the bell of the medusa possessing them, and consequently control the rate of pulsation. The bell pulsates at the rate of whichever organ is initiating stimuli most rapidly at a given time. The sense organs also appear to exert an influence on the general metabolic activities of the animal.

Stinging Capsules.—The cnidoblasts with their explosive capsules or *cnidae* will now be described (fig. 9). These capsules are among the most extraordinary structures to be found in the animal kingdom, and the physiological problem presented by the question of their explosion is a difficult one. It is probable that several factors are involved, and that these are called into play in fluctuating intensity according to the structure of the capsule and cnidoblast in question. Each cnida is a refringent transparent capsule with a gelatinous or more probably fluid content. In unexploded state, the capsule contains a hollow thread (*i.e.*, a capillary tube of incredible fineness) coiled or folded up within it; and the wall of capsule and

thread are continuous with one another at one pole of the capsule. The cell (*cnidoblast*) in which the capsule lies and which originally produced it, bears at its free surface a fine hair-like projection, known as a *cnidocil*. The contact of a foreign body with this cnidocil leads directly to the explosion of the capsule, but it is possible that this can also be effected by the nervous system. On the other hand such contact does not necessarily explode the capsule. For instance the reactions of a well-fed sea anemone are not the same as those of a hungry one; the tentacles may refuse food altogether, neither the tactile nor the chemical stimuli involved producing any effect on the capsules. When, however, a capsule does explode the thread is shot forth instantaneously. Although the action is so rapid, the thread as it is ejected turns completely inside out, in the manner in which one may turn the finger of a glove; in other words it is evaginated.

The structure of both *cnidae* and *cnidoblasts* varies greatly from one Coelenterate to another, and both may be complex. The *cnidoblast* possesses, in a number of cases at least, contractile fibres of varying disposition, and may also contain a coiled spring-like structure (the *lasso*) which probably resists the tearing away of the nematoblast from the tissues by a struggling prey. In a typical *cnida* the thread is provided with a series of spirally arranged barbs which help to fix it in the tissues of the prey, and bears with it poison which enters by the wound it has made. This kind of *cnida*, which is very frequent, is known as a *nematocyst*, in contrast to another type common in sea anemones and known as a *spirocyst*. The latter has no armature, but the outer surface of its evaginated thread has strongly adhesive properties, and is probably not poisonous.

True *cnidae* occur nowhere in the animal kingdom save in the Coelenterata. There are similar structures developed in at least two other kinds of animals (the Myxosporidean Protozoa and certain Nemertine worms), but they are not exactly the same; a number of other structures which have been confused with nematocysts are not actually such. The most interesting cases which have been investigated in this connection are those of certain animals in whose tissues actual Coelenterate nematocysts are present in an unexploded and functional condition. It has been conclusively shown that an animal may feed upon a Coelenterate, thus swallowing quantities of nematocysts, and that a number of these may pass unexploded through its food-canal, and may subsequently become arranged in a definite manner in its tissues. The best known instance of this is provided by certain of the

Nudibranch molluscs or sea slugs. In some cases at least these stolen nematocysts appear to be of value to their host.

Nematocysts and spirocysts, which are produced by interstitial cells, are not developed in the place where they will function. In some cases this means simply that they develop in the deeper layers of the epithelium and move up to the surface as they mature. In other cases however a much more interesting story is involved. The capsules are here secreted by *cnidoblasts* far removed from the site of their ultimate explosion, and in order to bring them into the situation and orientation which will permit them to function, the *cnidoblasts*, which are amoeboid and possess the power of independent movement, drag their capsules between the epithelial cells (or transport them by other means) until the proper locality is reached. A most interesting example of the processes involved is supplied by the state of affairs which exists in an unusual jellyfish known as *Halicyllistus* (see SCYPHOZOA, fig. 4, for an illustration). This animal has the edge of its bell produced into eight arms, each tipped by a tuft of tentacles; and on the middle of the outside of the bell it bears a stalk by the end of which it can attach itself to seaweed and other objects. It has been found that the tentacles contain two kinds of nematocyst, and that both kinds are produced in definite parts of the ectoderm of the inner surface of the bell. It has further been discovered that the *cnidoblasts* containing the two kinds of capsules migrate from their nursery to the tentacles; but that on the way some of those of one pattern (and not those of the other) disappear into little ectodermal pockets which lie close to the margin of the bell. The function of the pockets appears to be that of reservoirs whence a supply of capsules may be drawn in case of special need—for instance, if the tentacles belonging to one side of the animal be cut off, new ones are regenerated and a large supply of capsules is needed to stock them; and it has been found that under such circumstances the pockets nearest to the regenerating tentacles were empty.

Reproduction.—Coelenterates reproduce their kind in a variety of ways. They produce in the manner common to animals, eggs and spermatozoa, which after union develop into new creatures. But in addition to this universal method they have an extraordinarily strong tendency toward "vegetative" or asexual modes of reproduction, and correlated with this a very marked ability to regenerate lost parts. This manner of increase is much like the ability of a strawberry-plant to produce runners. It exists under a variety of forms; sometimes an animal within the space of a few hours or less will tear itself completely in half vertically; each half will regenerate new parts and will so develop into a complete animal. This process is known as fission; it does not always take the form of actual tearing, but may result from a gradual process of constriction whereby an individual separates either completely into halves or becomes partly double. In other varieties of fission the separation into two or more parts

takes place horizontally; and again, neither in vertical nor horizontal fission does it follow that the pieces formed will be at all equal in size. Equally characteristic of Coelenterates, but generally speaking of different ones, is the process known as budding (figs. 4 and 10). In this case a polyp may send out a rootlet (like the strawberry-runner) at the end of which a new polyp grows up; or a new polyp may arise direct from the tissues of an existing one. Polyps give rise by budding to other polyps or to medusae; medusae by budding may produce fresh medusae but never polyps.

these being always developed from eggs or from other polyps. The processes of regeneration which succeed certain types of asexual reproduction are both definite and interesting; and the regenerative results which arise from the cutting away of various parts of Coelenterates, or from the division of these animals into portions by cuts in different directions, provide material for a study from which much of general biological interest may be gained. Further details relating to budding and fission will be found in the articles HYDROZOA, SCYPHOZOA, and ANTHOZOA, whilst for information relating to regeneration reference should be made to the article on that subject.

Commensalism and Symbiosis.—There are to be found among the Coelenterata a number of examples of those types of relationship between one organism and another which are respectively known as *commensalism* and *symbiosis*. Commensalism, as exemplified by the regular partnership which exists between certain sea anemones and hermit crabs, is well represented in the group (see also next section); and a number of Coelenterata contain in their tissues those unicellular symbiotic Algae known as *Zooxanthellae*.

The Poison of Coelenterates.—A certain amount of work has been done on the lines of making extracts of one sort and another of the tissues of Coelenterates and injecting these into other animals in order to study the effect of the poison of the Coelenterate on the animal in question. It has been known for a long time that the poisons of certain Coelenterates are very virulent and that contact of the stinging organs with human skin may produce serious results. In the case of medusae belonging to the *Charybdaeidae* for instance, jellyfish which outstrip all others in the strength and rapidity of their swimming-movements, the stinging organs may cause intense pain after contact with the skin, and symptoms such as swelling of the legs, etc., follow; fatal results may even ensue. A recent investigation of particular interest has been made on the poison of *Adamsia palliata*, which not only throws light on the question of Coelenterate poisons but also upon the relationship between this anemone and another animal. *Adamsia palliata* lives in permanent association with a hermit crab known as *Eupagurus prideauxi*, and apparently these two organisms never normally occur apart. The soft tail-end of the crab is protected by the anemone, which is wrapped round it like a cloak; and the mouth of the anemone lies just below that of the crab, so that meals become a communal affair. Now it is possible to make an extract containing the poison of the tentacles or other stinging organs of an *Adamsia*, and such extracts have been injected in varying strengths into a number of animals. Certain of these, for instance Cephalopod molluscs (cuttle-fishes, etc.) and other sea anemones, appear to be completely immune from the *Adamsia* poison; other animals succumb to it. It has been found that the Decapod Crustacea (crabs, etc.) are the most sensitive to it, and its action on a number of these has been studied.

The following experiment is a case in point. Three shore-crabs (*Carcinus maenas*), three common hermit-crabs (*Eupagurus bernhardus*) and three of the hermits proper to *Adamsia* (*E. prideauxi*) were selected, and into the body-cavity of each was injected 0.1 c.c. of a filtered maceration of *Adamsia*. At the end of three minutes the *bernhardi* were completely paralysed after a short phase of tetanization; and at the end of an hour they were dead. The shore-crabs died between five and nine hours after having exhibited the symptoms characteristic of this poison. On

the other hand the *prideauxi* showed no apparent trouble; they retained all their agility and all the accustomed vivacity of their movements. At the end of 24 hours their condition was normal and they survived indefinitely. Other experiments confirm the result of this one, and the interesting fact emerges that *E. prideauxi* is immune from the poison of its anemone unless injected in inordinately large amount. Thus the association between the two animals includes a physiological as well as a morphological adaptation. It has been shown further that the serum of *E. prideauxi* is able to neutralize the *Adamsia* poison and that if a shore-crab be inoculated with *prideauxi* serum, it can afterwards withstand and recover from a dose of poison which would otherwise be fatal. It is probable that *E. prideauxi* gains its immunity in the first instance as a result of the fact that its close association with the anemone involves the constant entanglement of small portions of the latter, or of stinging cells derived from it, in the hermit's food. The intestinal content of the hermit usually contains such fragments of the anemone. Although in these experiments the poison of *Adamsia* did no harm to other anemones, yet in other cases one anemone may sting another, even of the same kind, and produce a wound which may prove fatal—so that an anemone is not necessarily immune from poison produced by its own kind. It is possible, however, that the injured animal in such cases is, to begin with, in a poor condition.

Distribution, Environment and Length of Life.—The distribution of the Coelenterata is world-wide, but the great majority are marine; a few kinds only inhabit brackish or fresh water, and these are further mentioned in the articles HYDROZOA and ANTHOZOA. The mass of Coelenterata then, inhabit one or other of the regions of the sea; and it cannot be said that they are characteristic of one kind of habitat more than of another. Many of them inhabit the littoral zone between tide-marks. Others colonize the sea-floor at greater or lesser depths, some of them occurring in extremely deep water (e.g., 2,900 fathoms). The remainder are pelagic at varying depths and may live in the open sea, some of them floating and some swimming. A number of Coelenterates are perennial, living for a number of years, their length of life in some cases probably being extremely great. The best measured example of this is that of some sea anemones at present alive, which are known to be at least 70 years old and may be much more. Other Coelenterates, on the other hand, are seasonal; many hydroids die down in winter and regenerate new polyps in spring; and many medusae live for a brief period only. Neither the tropics nor the cold regions can be regarded as the more typical habitat for Coelenterata, though it is true that corals, anemones and Siphonophores for instance, attain their maximum profusion or considerable complexity of development (sometimes both these features) in the warm seas. The variety of Coelenterates which may occur within a broadly similar environment is great, but as in the case of many other animals a certain proportion at least of the genera permanently colonizing the various available habitats show a sympathetic reaction to their environment; thus it may be expected with reason that an average anemone living at great depths will be different from a typical inhabitant of a coral-reef, and a typical mud-dweller from an ordinary adherent form. Certain single species however range in suitable habitats from the Arctic to the Equator, others occur both in the Arctic and the Antarctic; whilst some are circumpolar in distribution. With regard to the distribution of jellyfish it may be noted that their swimming powers are adapted rather for maintaining their position in the water and for moving up and down in it than for making long journeys; the main agents in their distribution are currents and tides.

Classification.—The Coelenterata are divided into three great classes, the *Hydrozoa*, *Scyphozoa* and *Anthozoa*. To these are sometimes added the *Ctenophora*; but the latter are animals which are actually very different from any Coelenterata, and the reasons which lead to this conclusion are stated in the article dealing with them. The characteristics of the three great classes of Coelenterata are also described in articles dealing with each series separately.

COELLO, ALONSO SANCHEZ (1515-1590), Spanish painter, according to some authorities a native of Portugal, was born, according to others, at Benifacio, near the city of Valencia. He studied many years in Italy; and returning to Spain in 1541 he settled at Madrid, and worked on religious themes for most of the palaces and larger churches. He was a follower of Titian, and, like him, excelled in portraits and single figures, elaborating the textures of his armours, draperies, and such accessories in a manner so masterly as strongly to influence Velazquez in his treatment of like objects. Many of his pictures were destroyed in the fires that consumed the Madrid and Prado palaces, but many good examples are yet extant, among which may be noted the portraits of the infantes Carlos and Isabella, now in the Madrid gallery, and the St. Sebastian painted in the church of San Gerónimo, also in Madrid. Coello left a daughter, Isabella Sanchez, who studied under him, and painted excellent portraits.

COELLO, ANTONIO (1611-1652), Spanish dramatist and poet, was born at Madrid and entered the household of the duke of Albuquerque. His best known plays are *El conde de Sex*, *El Celoso extremeño* (dramatizing one of Cervantes' *Novelas Exemplares*) and *Los Empeños de seis horas*. The latter was adapted by Samuel Tuke, under the title of *The Adventures of five Hours*, and was described by Pepys as superior to *Othello*.

COELLO, CLAUDIO (c. 1630-1693), Spanish painter born at Madrid, son of a well-known worker in bronze of Portuguese origin. He studied under Francisco Rizi, and was dominated at first by an overcharged, exaggerated style, which was then beginning to be admired in Madrid. He assisted his master in the execution of an altarpiece for S. Plácido. He then studied and copied the works of Titian, Rubens and Van Dyck in the royal collections, to which he secured access through his friendship with the court painter D. Juan Carreño. He also profited by his friendship with Josef Donoso, who had studied seven years in Rome, and, with his co-operation, painted frescoes in some churches and palaces of Madrid. In 1671 he decorated the ceiling of the vestry in Toledo cathedral. In 1683 he was commissioned by the archbishop of Saragossa to paint frescoes in the cupola and the transept of the Augustine church. On his return to Madrid he became court painter to King Charles II., and undertook the altarpiece for the sacristy in the Escorial representing the "Transfer of the Holy Eucharist." The scene is represented as taking place in the same room in which the picture is hung. It is a fine arrangement of space in the baroque style containing some 50 life-like portraits including that of Charles II. and his prime minister. This work is his masterpiece. It is nearly allied to the realistic art of Velasquez and Carreño, and Coello here shows himself as a brilliant and strong colourist, a fine and careful draughtsman. He seems to have tried to stem the decadence, which was engulfing Spanish art. His work was universally admired, he was appointed Seneschal and his son received a pension of 300 ducats. Then Luca Giordano arrived in 1692. The preference shown by the court to the Italian favourite, hurt Coello's sensitive nature. His last work was the "Martyrdom of St. Stephen," painted for the Dominican church at Salamanca. He died on April 2, 1693, at Madrid, and was buried in the church of San Andres. He was the last important master of

the great Madrid school of the 17th century.

His works are to be seen in the churches of Madrid and other cities of Spain, at the Prado, in the galleries of Munich, Budapest and Frankfurt. "The Betrothal," presented to the National Gallery, London, as by Velazquez, is perhaps an early work by Coello, who is also represented in the collections at Apsley house and Grosvenor house.

See A. de Beruete y Moret, *The School of Madrid* (1909).

COELOM AND SEROUS MEMBRANES. In human anatomy the body-cavity or coelom is divided into the *pericardium*, the two *pleurae*, the *peritoneum* and the two *tunicae vaginales*.

The *pericardium* is a closed sac in the thorax and contains the heart. Like all the serous membranes it has a visceral and a parietal layer, the former being closely applied to the heart and consisting of endothelial cells with a slight fibrous backing: to it is due the glossy appearance of a freshly removed heart. The parietal layer is double; externally there is a strong fibrous coat continuous with the other fibrous structures in the neighbourhood, while internally is the endothelial layer which is reflected from the surface of the heart, where the great vessels enter. Hence everywhere the two layers of the membrane are in contact except for a trace of fluid secreted by the serous walls.

The *pleurae* resemble the pericardium except that the fibrous outer coat of the parietal layer is not nearly as strong; it is closely attached to the inner surface of the chest walls and mesially to the outer layer of the pericardium; above it is thickened by a fibrous contribution from the scalene muscles, and forms the *dome of the pleura* which fits into the concavity of the first rib and contains the apex of the lung. The reflection of the serous layer of the pleura, from the parietal to the visceral part, takes place at the root of the lung. The upper limit of the pleural cavity reaches about half an inch above the inner third of the clavicle, while, below, it may be marked out by a line drawn from the twelfth thoracic spine to the tenth rib in the mid axillary line, the eighth in the nipple line, and the sixth at its junction with the sternum.

The *peritoneum* is a more extensive and complicated membrane; it surrounds the abdominal and pelvic viscera, and, like the other sacs, has a parietal and visceral layer. The line of reflection of these, though continuous, is very tortuous. The peritoneum consists of a *greater* and *lesser sac*

which communicate through an opening (*foramen of Winslow*) and the best way of understanding these is to follow the reflections first in a vertical median (sagittal) section and then in a horizontal one, the body being supposed to be in the upright position. If a median sagittal section be studied first, and a start be made at the umbilicus (see fig. 1), the parietal peritoneum is seen to run upward, lining the anterior abdominal wall, and then to pass along the under surface of the diaphragm till its posterior third is reached; here there is a reflection on to the liver, forming the anterior layer of the *coronary ligament* of that viscus, while the membrane now becomes visceral and envelops the front of the liver as far back as the transverse fissure on its lower surface; here it is reflected on to the stomach forming the anterior layer of the *gastro-hepatic* or *lesser omentum*. It now covers the front of the stomach, and at the lower border runs down as the anterior layer of an apron-like fold, the *great omentum*, which sometimes reaches as low as the pubes; then it turns up again as the posterior or fourth layer of the great omentum until the transverse colon is reached, the posterior surface of which it covers and is reflected, as the

FIG. 1.—VERTICAL MEDIAN SECTION OF ABDOMEN TO SHOW ARRANGEMENT OF THE PERITONEUM. The peritoneum is indicated by a dotted line for the greater sac and a broken line for the lesser sac.

posterior layer of the *transverse mesocolon* to the lower part of the pancreas; after this it turns down and covers the anterior surface of the third part of the duodenum till the posterior wall of the abdomen is reached, from which it is reflected on to the small intestine as the anterior layer of the *mesentery*, a fold varying from 5 to 8 in. between its attachments. After surrounding the small intestine it becomes the posterior layer of the mesentery and so again reaches the posterior abdominal wall, down which it runs until the rectum is reached. The anterior surface of this tube is covered by peritoneum to a point about 3 in. from the anus, where it is reflected on to the uterus and vagina in the female and then on to the bladder; while in the male, on the other hand, the reflection is directly from the rectum to the bladder. At the apex of the bladder, after covering the upper surface of that organ, it is lifted off by the urachus and runs up the anterior abdominal wall to the umbilicus, from which the start was made. All this is the greater sac. The tracing of the lesser sac may be conveniently started at the transverse fissure of the liver, whence the membrane runs down to the stomach as the posterior layer of the lesser omentum, lines the posterior surface of the stomach, passes down as the second layer of the great omentum and up again as the third layer, covers the anterior surface of the transverse colon and then reaches the pancreas as the anterior layer of the transverse mesocolon. After this it covers the front of the pancreas and in the middle line of the body runs up below the diaphragm to within an inch of the anterior layer of the coronary ligament of the liver; here it is reflected on to the top of the Spigelian lobe of the liver to form the posterior layer of the coronary ligament, covers the whole Spigelian lobe, and so reaches the transverse fissure.

This section, therefore, shows two completely closed sacs without any visible communication. In the female, however, the great sac is not absolutely closed, for the Fallopian tubes open into it by their minute *ostia abdominalia*, while at the other ends they communicate with the cavity of the uterus and so with the vagina and exterior.

A horizontal section through the upper part of the first lumbar vertebra will, if a fortunate one (*see fig. 2*), pass through the foramen of Winslow and show the communication of the two sacs. A starting-point may be made from the mid-ventral line and the parietal peritoneum traced round the left side of the body wall until the outer edge of the left kidney is reached; here it passes in front of the kidney and is soon reflected off on to the spleen, which it nearly surrounds; just before it reaches the hilum of that organ, where the vessels enter, it is reflected on to the front of the stomach, forming the anterior layer of the *gastro-splenic omentum*; it soon reaches the lesser curvature of the stomach and then becomes the anterior layer of the lesser omen-

FIG. 2.—HORIZONTAL SECTION THROUGH UPPER PART OF FIRST LUMBAR VERTEBRA, SHOWING ARRANGEMENT OF THE PERITONEUM

tum, which continues until the bile duct and portal vein are reached at its right free extremity; here it turns completely round these structures and runs to the left again, as the posterior layer of the lesser omentum, behind the stomach and then to the spleen as the posterior layer of the gastro-splenic omentum. From the spleen it runs to the right once more, in front of the pancreas, until the inferior vena cava is reached, and this point is just behind the portal vein and is the place where the lesser and greater sacs communicate, known as the foramen of Winslow. From this opening the lesser sac runs

to the left, while all the rest of the peritoneal cavity in the section is greater sac. From the front of the vena cava the parietal peritoneum passes in front of the right kidney and round the right abdominal wall to the mid-ventral line. The right part of this section is filled by the liver, which is completely surrounded by a visceral layer of peritoneum, and no reflection is usually seen at this level between it and the parietal layer. Some of

FROM CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD UNIVERSITY PRESS)

FIG. 3.—LONGITUDINAL SECTION SHOWING THE DIFFERENT AREAS OF THE BLASTODERMIC VESICLE IN EARLY DEVELOPMENT OF THE OVUM

the viscera, such as the kidneys and pancreas, are retro-peritoneal; others, such as the small intestines and transverse colon, are surrounded, except at one point where they are attached to the dorsal wall by a *mesentery* or *mesocolon* as the reflections are called; others again are completely surrounded, and of these the caecum is an example; while some, like the liver and bladder, have large uncovered areas, and the reflections of the membrane form ligaments which allow considerable freedom of movement.

The *tunica vaginalis* is the remains of a peritoneal pocket which descends into the scrotum during foetal life before the testis itself descends. After the descent of the testis the upper part usually becomes obliterated, while the lower part forms a serous sac which nearly surrounds the testis. The parietal layer lines the inner wall of its own side of the scrotum.

Embryology.—As the mesoderm spreads over the embryo it splits into two layers, the outer of which (*somatopleure*) lines the parietal or ectodermal wall, while the inner lines the entoderm (*splanchnopleure*); between the two is the coelom. The pericardial area is early differentiated from the rest of the coelom and at first lies in front of the neural and bucco-pharyngeal area; here the mesoderm stretches right across the mid-line, which it does not in front and behind. As the head of the embryo is formed the pericardium is gradually turned right over, so that the dorsal side becomes the ventral and the anterior limit the posterior; this will be evident on referring to figs. 3 and 4.

The two primitive aortae lie at first in the ventral wall of the pericardium, but with the folding over they come to lie in the dorsal wall and gradually bulge into the cavity as they coalesce to form the heart, so that the heart drops into the dorsal side of the pericardium and draws down a fold of the membrane called the *dorsal mesocardium*. In mammals A. Robinson (*Jour. Anat. and Phys.*, xxxvii. 1) has shown that no ventral mesocardium exists, though in more lowly vertebrates it is present. Laterally the pericardial cavity communicates with the general cavity of the coelom, but with the growth of the Cuvierian ducts (*see development of veins*) these communications disappear. Originally the mesocardium runs the whole length of the pericardium from before backward, but later on the middle part becomes obliterated.

Just behind the pericardium and in front of the umbilicus, which at first are close together, the mesoderm forms a mass into which the developing lungs push bag-like protrusions of the coelom. These lose their connection with the rest of the coelom, as the diaphragm develops, and become the pleural cavities. The remainder of the coelom persists as the peritoneum. At first the stomach and intestine form a straight tube, connected to the dorsum of the embryo by a *dorsal mesentery* and to the mid-ventral wall in front of the umbilicus by a *ventral mesentery*. Into the ventral mesentery the liver grows as diverticula from the duodenum, so that some of the mesentery remains as the *falciform ligament* of the liver and some as the lesser omentum. Into the

dorsal mesentery the pancreas grows, also as diverticula, from the duodenum, while the spleen is developed from the mesoderm contained in the same fold. As the stomach turns over and its left side becomes ventral, the dorsal mesentery attached to it is pulled out, so that part forms the great omentum and part the gastrosplenic omentum. When the caecum is formed as a diverticulum from the intestine it is close to the liver but gradually travels down into the right iliac fossa. This passage to the right is accompanied by a throwing over of the duodenal loop to the right, so that the right side of its mesentery becomes pressed against the dorsal wall of the abdomen and obliterated. This accounts for the fact that the pancreas and duodenum are only covered by peritoneum on their anterior surfaces in man. The formation of the lesser sac is due to the turning over of the stomach to the right, with the result that a cave is formed behind it. Originally the whole colon had a *dorsal mesocolon* continuous with the mesentery, but in the region of the ascending and descending colon this usually disappears and these parts of the gut are uncovered by peritoneum posteriorly. The transverse mesocolon persists and at first is quite free from the great omentum, but later, in man, the fourth layer of the great omentum becomes continuous with the posterior layer of the transverse mesocolon.

Comparative Anatomy.—In *Amphioxus* the coelom is developed in the embryo as a series of bilateral pouches from the sides of the alimentary canal; these are therefore entodermal in their origin, as in *Sagitta* and the Echinodermata among the invertebrates. In the adult the coelom is represented by two dorsal canals communicating with a ventral canal by means of branchial canals which run down the outer side of the primary gill bars. Into the dorsal canals the nephridia open. In the intestinal region the coelom is only present on the left side.

In the higher vertebrates (*Craniata*) the coelom is developed by a splitting of the mesoderm into two layers, and a pericardium is constricted off from the general cavity. In all cases the ova burst into the coelom before making their way to the exterior, and in some, e.g., *Amphioxus*, lamprey (Cyclostomata), eels and mud-fish (Dipnoi), the sperm cells do so too. The Cyclostomata have a pair of *genital pores* which lead from the coelom into the urinogenital sinus, and so to the exterior.

In the Elasmobranch fish there is a *pericardio-peritoneal canal* forming a communication between these two parts of the coelom;

AFTER YOUNG AND ROBINSON, FROM CUNNINGHAM, "TEXT-BOOK OF ANATOMY"

FIG. 4.—LONGITUDINAL SECTION SHOWING RELATION OF PARTS TO SEROUS MEMBRANES IN THE EARLY DEVELOPING EMBRYO

also a large common opening for the two oviducts in the region of the liver, and two openings (*abdominal pores*) on the surface close to the cloacal aperture. In the Teleostomi (Teleostean and Ganoid fish) abdominal pores are rare, but in most Teleostei (bony fish) the ova pass directly down oviducts, as they do in arthropods, without entering the peritoneal cavity; there is little doubt, however, that these oviducts are originally coelomic in origin. In the Dipnoi (mud-fish) abdominal pores are found, and probably serve as a passage for the sperm cells, since there are no vasa deferentia. In fishes a complete dorsal mesentery is sel-

dom found in the adult; in many cases it only remains as a tube surrounding the vessels passing to the alimentary canal.

In the Amphibia, Reptilia and Aves, one cavity acts as pleura and peritoneum, though in the latter the lungs are not completely surrounded by a serous membrane. In many lizards the comparatively straight intestine, with its continuous dorsal mesentery and ventral mesentery in the anterior part of the abdomen, is very like a stage in the development of the human and other mammalian embryos. In the mammalia the diaphragm is complete (*see* DIAPHRAGM) and divides the pleuroperitoneal cavity into its two constituent parts. In the lower mammals the derivatives of the original dorsal mesentery do not undergo as much fusion and obliteration as they do in adult man; the ascending and descending mesocolon is retained, and the transverse mesocolon contracts no adhesion to the great omentum. It is common, however, to find a fenestrated arrangement of the great omentum which shows that its layers have been completely obliterated in many places.

In those animals, such as the rabbit, in which the testes are sometimes in the scrotum and sometimes in the abdomen, the communication between the peritoneum and the tunica vaginalis remains throughout life.

BIBLIOGRAPHY.—Full bibliography in Quain's *Anatomy*.

COELOMATA, a term used in zoology to denote those animals in which the primary body cavity (enteron) has become divided into an alimentary canal and a coelom (*q.v.*). This has occurred in all animals above the flat-worms (Platyhelminthes). Animals with no coelom are collectively termed Acoelomata (*q.v.*).

COELOSTAT, a mirror driven by clock-work so as to reflect continually the same region of the sky into the field of view of a fixed telescope. The mirror is mounted so as to rotate about an axis in its own plane which points to the pole of the heavens, and is driven at the rate of one revolution in 48 (sidereal) hours. The image of a star seen in the mirror is then stationary. The device is particularly useful in eclipse expeditions when elaborate equatorial mounting of the telescopes is impossible. Other instruments for somewhat similar purposes are the heliostat and siderostat (*q.v.*).

COEN, JAN PIETERSZOOM (1587–1630), fourth governor-general of the Dutch East Indies, was born at Hoorn, and spent his youth at Rome in the house of the famous merchants the Piscatori. In 1607 he sailed from Amsterdam to the Indies as second commercial agent, and remained away four years. In 1612 he was sent out at the head of a trading expedition. In 1613 he was made a councillor and director-general of the East Indian trade. Afterwards he became president at Bantam, and on Oct. 31, 1617, he was promoted in succession to Laurens Reaal to the post of governor-general. To his vigour and intrepidity the Dutch in no small measure owed the preservation and establishment of their empire in the East. He took and destroyed Jacatra, and founded on its ruins the capital of the Dutch East Indies, to which he gave the name of Batavia. In 1622 Coen obtained leave to resign his post and return to Holland, but in his absence great difficulties had arisen with the English at Amboina (the so-called massacre of Amboina), and in 1627 under pressure from the directors of the East India Company he returned as governor-general to Batavia. In 1629 he was able to beat off a formidable attack of the sultan of Mataram, sometimes styled emperor of Java, upon Batavia.

COENWULF (d. 821), king of Mercia, successor of Ecgrith, son of Offa, in 796. In 798 he invaded Kent, imprisoned Eadberht Praen, and made his own brother Cuthred king. On Cuthred's death (807) Coenwulf seems to have taken Kent into his own hands. He abolished the archbishopric of Lichfield, probably before 803, as the Hygeberht who signed as an abbot at the council of Cloveshoe in that year was presumably the former archbishop. Coenwulf appears from the charters to have had a long dispute with Wulfred of Canterbury, who was consecrated in 806. It was probably only settled in 825, when the lawsuit of Cwoenthryth, his daughter, with Wulfred was terminated. He died in 821 and was succeeded by his brother Ceolwulf I.

See Earle and Plummer's edition of the *Anglo-Saxon Chronicle*.

796, 819 (Oxford, 1892); W. de G. Birch, *Cartularium Saxonicum*, 378 (1885-93).

COERCION, an application of moral or physical compulsion by which a person is forced to do or refrain from doing some act apart from his own voluntary motion. Where the coercion is direct or positive, *i.e.*, where the person is compelled by physical force to do an act contrary to his will, his act is not legally a crime. Where the coercion is implied as where moral force is used, the person coerced is responsible, as in the case of duress or threats. Formerly where a married woman committed a crime in the presence of her husband she was presumed to have acted by his coercion and to be entitled to acquittal. Now by s. 47 of the Criminal Justice Act 1925 any such presumption is abolished; but on a charge against a wife for any offence other than treason or murder it is a good defence to show that the offence was committed in the presence of and under the coercion of her husband. In civil matters, such as the making of a contract, where the law requires the free assent of the person who undertakes the obligation, coercion is a ground for invalidating the instrument.

COEUR, JACQUES (c. 1395-1456), founder of the trade between France and the Levant, was born at Bourges, the son of a rich merchant. About 1429 he formed a commercial partnership with two brothers named Godard; and in 1432 he was at Damascus, buying and transporting to France the wares of the Levant. Within a few years he placed his country in a position to contend not unsuccessfully with the great trading republics of Italy, and acquired such reputation as to be able to render material assistance to the knights of Rhodes and to Venice herself.

In 1436 Coeur was summoned to Paris by Charles VII., and made master of the mint. The country was at that time deluged with the base moneys of three reigns, charged with superscriptions both French and English, and Charles had determined on a sweeping reform. Jacques Coeur inspired or prepared all the ordinances concerning the coinage of France issued between 1435 and 1451. In 1438 he was made steward of the royal expenditure; in 1441 he and his family were ennobled by letters patent. In 1444 he was sent as one of the royal commissioners to preside over the new *parlement* of Languedoc. In 1445 his agents in the East negotiated a treaty between the sultan of Egypt and the knights of Rhodes; and in 1447, at his instance, Jean de Village, his nephew by marriage, was charged with a mission to Egypt. The results were most important; concessions were obtained which greatly improved the position of the French consuls in the Levant and laid the foundations of the important French commerce in the Near East. In the same year Coeur took part in a mission to Amadeus VIII., former duke of Savoy, who had been chosen pope as Felix V. by the council of Basel. In 1448 he represented the French king at the court of Pope Nicholas V., and was able to arrange an agreement between Nicholas and Amadeus, and so to end the papal schism. From about this time he made large advances to Charles for carrying on his wars; and in 1449, after fighting at the king's side through the campaign, he entered Rouen in his train.

At this moment the great trader's glory was at its height. He had represented France in three embassies, and had supplied the sinews of that war which had ousted the English from Normandy. He was invested with various offices of dignity, and possessed the most colossal fortune that had ever been amassed by a private Frenchman. The sea was covered with his ships; he had 300 factors in his employ, and houses of business in all the chief cities of France. He had built houses and chapels, and had founded colleges in Paris, at Montpellier and at Bourges. The magnificent house at Bourges remains to-day one of the finest monuments of the middle ages in France. He also built there the sacristy of the cathedral and a sepulchral chapel for his family. His brother Nicholas was made bishop of Luçon, his sister married Jean Bochetel, the king's secretary, his daughter married the son of the viscount of Bourges, and his son Jean became archbishop of Bourges.

In Feb. 1450 Agnes Sorel, the king's mistress, suddenly died. Eighteen months later it was rumoured that she had been poisoned, and Jacques Coeur was accused of having poisoned her by Jeanne de Vendôme, wife of François de Montberon, and an Italian,

Jacques Colonna. There was not even a pretext for such a charge, but for this and other alleged crimes the king, on July 31, 1451, gave orders for his arrest and for the seizure of his goods, reserving to himself a large sum of money for the war in Guienne. Commissioners extraordinary, the merchant's declared enemies, were chosen to conduct the trial, and an enquiry began, the judges in which were either the prisoner's debtors or the holders of his forfeited estates. A conviction was indispensable, and after 22 months of confinement, he was condemned to do public penance for his fault, to pay the king a sum equal to about £1,000,000 of modern money, and to remain a prisoner till full satisfaction had been obtained; his sentence also embraced confiscation of all his property, and exile during royal pleasure. For nearly three years nothing is known of him. It is probable that he remained in prison; it is certain that his vast possessions were distributed among the intimates of Charles.

In 1455 Jacques Coeur, wherever confined, contrived to escape into Provence. He was pursued; but a party, headed by Jean de Village and two of his old factors, carried him off to Tarascon, whence, by way of Marseilles, Nice and Pisa, he managed to reach Rome. He was honourably and joyfully received by Nicholas V., who was fitting out an expedition against the Turks. On the death of Nicholas, Calixtus III. continued his work, and named his guest captain of a fleet of 16 galleys sent to the relief of Rhodes. Coeur set out on this expedition, but was taken ill at Chios, and died there on Nov. 25, 1456.

See the admirable monograph of Pierre Clément, *Jacques Coeur et Charles VII.* (1858, 2nd ed. 1874); A. B. Kerr, *Jacques Coeur* (1927).

COEUR D'ALÈNE, a tribe of North American Indians of Salishan stock. The name is said to have been originally that of a chief noted for his cruelty.

COEUR D'ALENE, a city of Idaho, U.S.A., 33m. E. of Spokane, at the head of Lake Coeur d'Alene; the county seat of Kootenai county. It is on Federal highways 10 and 95, and is served by the Northern Pacific, the Chicago, Milwaukee, St. Paul and Pacific, and the Inland Empire (electric) railways. The population in 1920 was 6,447; and was 8,297 in 1930 by the Federal census. It is in the rich lumbering, mining and agricultural region known as the "inland empire." The city has saw and planing mills, boat-building yards and a railroad-tie factory. It was settled about 1880, and incorporated in 1889.

COFFEE. This important and valuable article of food is the produce chiefly of *Coffea arabica*, a Rubiaceae plant indigenous to Abyssinia, which, however, as cultivated originally, spread outwards from the southern parts of Arabia. The name is probably derived from the Arabic K'hawah, although by some it has been traced to Kaffa, a province in Abyssinia, in which the tree grows wild.

The genus *Coffea*, to which the common coffee tree belongs, contains about 25 species in the tropics of the Old World, mainly African. Besides being found wild in Abyssinia, the common coffee plant appears to be widely disseminated in Africa, occurring wild in the Mozambique district, on the shores of the Victoria Nyanza, and in Angola on the west coast. The coffee leaf disease in Ceylon brought into prominence a Liberian coffee (*C. liberica*), a native of the west coast of Africa, now extensively grown in several parts of the world. Other species of economic importance are Sierra Leone coffee (*C. stenophylla*) and Congo coffee (*C. robusta*), both of which have been introduced into and are cultivated on a small scale in various parts of the tropics. *C. excelsa* is another species of considerable promise.

The common Arabian coffee shrub is an evergreen plant, which under natural conditions grows to a height of from 18 to 20 ft., with oblong-ovate, acuminate, smooth and shining leaves, measuring about 6in. in length by 2½in. wide. Its flowers, which are produced in dense clusters in the axils of the leaves, have a five-toothed calyx, a tubular five-parted corolla, five stamens and a single bifid style. The flowers are pure white in colour, with a rich fragrant odour, and the plants in blossom have a lovely and attractive appearance, but the bloom is very evanescent. The fruit is a fleshy berry, having the appearance and size of a small

cherry, and as it ripens it assumes a dark red colour. Each fruit contains two seeds embedded in a yellowish pulp, and the seeds are enclosed in a thin membranous endocarp (the "parchment"). Between each seed and the parchment is a delicate covering called the "silver skin." The seeds which constitute the raw coffee "beans" of commerce are plano-convex in form, the flat surfaces which are laid against each other within the berry having a longitudinal furrow or groove. When only one seed is developed in a fruit it is not flattened on one side, but circular in cross section. Such seeds form "pea-berry" coffee.

The seeds are of a soft, semi-translucent, bluish or greenish colour, hard and tough in texture. The regions best adapted for the cultivation of coffee are well-watered mountain slopes at an elevation ranging from 1,000 to 4,000 ft. above sea-level, within the tropics, and possessing a mean annual temperature of about 65° to 70° F.

The Liberian coffee plant (*C. liberica*) has larger leaves, flower, and fruits, and is of a more robust and hardy constitution than Arabian coffee. The seeds yield a highly aromatic and well-flavoured coffee (but by no means equal to Arabian), and the plant is very prolific and yields heavy crops. Liberian coffee grows, moreover, at low altitudes, and flourishes in many situations unsuitable to the Arabian coffee. It grows wild in great abundance along the whole of the Guinea coast.

History of Coffee.—The early history of coffee as an economic product is involved in considerable obscurity, the absence of fact being compensated for by a profusion of conjectural statements and mythical stories. The use of coffee (*C. arabica*) in Abyssinia was recorded in the 15th century, and was then stated to have been practised from time immemorial. Neighbouring countries, however, appear to have been quite ignorant of its value. Its physiological action in dissipating drowsiness and preventing sleep was taken advantage of in connection with the prolonged religious service of the Mohammedans, and its use as a devotional antisoporific stirred up fierce opposition on the part of the strictly orthodox and conservative section of the priests. Coffee by them was held to be an intoxicating beverage, and therefore prohibited by the Koran, and severe penalties were threatened to those addicted to its use. Notwithstanding, the coffee-drinking habit spread rapidly among the Arabian Mohammedans, and the growth of coffee and its use as a national beverage became as inseparably connected with Arabia as tea is with China.

The appreciation of coffee as a beverage in Europe dates from the 17th century. "Coffee-houses" were soon instituted, the first being opened in Constantinople and Venice. In London coffee-houses date from 1652, when one was opened in St. Michael's Alley, Cornhill. They soon became popular, and the rôle played by them in the social life of the 17th and 18th centuries is well known. In Europe, as in Arabia, coffee at first made its way into favour in the face of various adverse and even prohibitive restrictions. Thus at one time in Germany it was necessary to obtain a licence to roast coffee. In England Charles II. endeavoured to suppress coffee-houses on the ground that they were centres of political agitation.

Up to the close of the 17th century, the world's entire, although limited, supply of coffee was obtained from the province of Yemen in south Arabia, where the true celebrated Mocha or Mokka cof-

fee is still produced. At this time, however, plants were successfully introduced from Arabia to Java, where the cultivation was immediately taken up. The government of Java distributed plants to various places, including the botanic garden of Amsterdam. The Portuguese introduced coffee into Ceylon. From Amsterdam the Dutch sent the plant to Surinam in 1718, and in the same year Jamaica received it through its governor, Sir Nicholas Lawes, whence it spread generally through the tropics of the New World, which now produce by far the greater portion of the world's supply.

Cultivation and Preparation for Market.—Coffee plants are grown from seeds, which, as in the case of other crops, should be obtained from selected trees of desirable characteristics. The seeds may be sown "at stake," i.e., in the actual positions the mature plants are to occupy, or raised in a nursery and afterwards transplanted. The choice of methods is usually determined by various local considerations. Nurseries are desirable where there is risk of drought killing seedlings in the open. Whilst young the plants usually require to be shaded, and this may be done by growing castor oil plants, cassava (*Manihot*), maize or Indian corn, bananas, or various other useful crops between the coffee, until the latter develop and occupy the ground. Sometimes, but by no means always, permanent shading is afforded by special shade trees, such as species of the coral tree (*Erythrina*) and other leguminous trees. Opinions as to the necessity of shade trees varies in different countries.

The plants begin to come into bearing in their second or third year, but on the average the fifth is the first year of considerable yield. There may be two, three, or even more "flushes" of blossom in one year, and flowers and fruits in all stages may thus be seen on one plant. The fruits are fully ripe about seven months after the flowers open; the ripe fruits are fleshy, and of a deep red colour, whence the name of "cherry." When mature the fruits are picked by hand, or allowed to fall of their own accord or by shaking the plant. The subsequent preparation may be according to (1) the dry or (2) the wet method.

In the dry method the cherries are spread in a thin layer, often on a stone drying floor, or barbecue, and exposed to the sun. Protection is necessary against heavy dew or rain. The dried cherries can be stored for any length of time, and later the dried pulp and the parchment are removed, setting free the two beans contained in each cherry. This primitive and simple method is employed in Arabia and other countries; in Brazil it has largely given place to the more modern method described below.

PICKING COFFEE BERRIES BY HAND
In order to facilitate the gathering of the berries, the tree is kept trimmed to a height of from 6 to 8 feet

Here they are subjected to the action of a roughened cylinder revolving closely against a curved iron plate. The fleshy portion is reduced to a pulp and the mixture of pulp and liberated seeds (each still enclosed in its parchment) is carried away to a second tank of water and stirred. The light pulp is removed by a stream of water and the seeds allowed to settle. Slight fermentation and subsequent washings, accompanied by trampling with bare feet and stirring by rakes or special machinery, result in the parchment coverings being left quite clean. The beans are now dried on barbecues, in trays, etc., or by artificial heat if climatic conditions render this necessary. Experiments in Porto

Rico tend to show that if the weather is unfavourable during the crop period the pulped coffee can be allowed to remain moist and even to malt or sprout without injury to the final value of the product when dried later. The product is now in the state known as parchment coffee, and may be exported. Before use, however, the parchment must be removed. This may be done on the estate, at the port of shipment, or in the country where imported. The coffee is thoroughly dried, the parchment broken by a roller, and removed by winnowing. Further rubbing and winnowing removes the silver skin, and the beans are left in the condition of ordinary unroasted coffee. Grading into large, medium and small beans, to secure the uniformity desirable in roasting, is effected by the use of a cylindrical or other pattern sieve, along which the beans are made to travel, encountering first small, then medium, and finally large apertures or meshes. Damaged beans and foreign matter are removed by hand picking. An average yield of cleaned coffee is from $1\frac{1}{2}$ to 2 lb. per tree, but much greater crops are obtained on new rich lands, and under special conditions.

Coffee-leaf Disease.—The coffee industry in Ceylon was ruined by the attack of a fungoid disease (*Hemileia vastatrix*) known as the Ceylon coffee-leaf disease. This has since extended its ravages into every coffee-producing country in the Old World, and added greatly to the difficulties of successful cultivation. The fungus is a microscopic one the minute spores of which, carried by the wind, settle and germinate upon the leaves of the plant. The fungal growth spreads through the substance to the leaf, robbing the leaf of its nourishment and causing it to wither and fall. An infected plantation may be cleansed, and the fungus in its nascent state destroyed, by powdering the trees with a mixture of lime and sulphur, but, unless the access of fresh spores brought by the wind can be arrested, the plantations may be readily reinfected when the lime and sulphur are washed off by rain. The separation of plantations by belts of trees to windward is suggested as a check to the spread of the disease.

Microscopic Structure.—Raw coffee seeds are tough and horny in structure, and are devoid of the peculiar aroma and taste which are so characteristic of the roasted seeds. The minute structure of coffee allows it to be readily recognized by means of the microscope, and as roasting does not destroy its distinguishing peculiarities, microscopic examination forms the readiest means of determining the genuineness of any sample. The substance of the seed, according to Dr. Hassall, consists "of an assemblage of vesicles or cells of an angular form, which adhere so firmly together that they break up into pieces rather than separate into distinct and perfect cells. The cavities of the cells include, in the form of little drops, a considerable quantity of aromatic volatile oil, on the presence of which the fragrance and many of the active principles of the berry depend."

Physiological Action.—Coffee belongs to the medicinal or auxiliary class of food substances, being solely valuable for its stimulant effect upon the nervous and vascular system. It produces a feeling of buoyancy and exhilaration comparable to a certain stage of alcoholic intoxication, but which does not end in depression or collapse. It increases the frequency of the pulse, lightens the sensation of fatigue, and it sustains the strength under prolonged and severe muscular exertion. The value of its hot infusion under the rigours of Arctic cold has been demonstrated in the experience of all Arctic explorers, and it is scarcely less useful in tropical regions, where it beneficially stimulates the action of the skin.

The physiological action of coffee mainly depends on the presence of the alkaloid caffeine, which occurs also in tea, Paraguay tea, and cola nuts, and is very similar to theobromine, the active principle in cocoa. The percentage of caffeine present varies in the different species of *Coffea*. In Arabian coffee it ranges from about 0.7 to 1.6%; in Liberian coffee from 1.0 to 1.5%. Sierra Leone coffee (*C. stenophylla*) contains from 1.52 to 1.70%; in *C. excelsa* 1.89% is recorded, and as much as 1.97% in *C. canephora*. Four species have been shown by M. G. Bertrand to contain no caffeine at all, but instead a considerable quantity of a bitter principle. All these four species are found only in Madagascar or the

neighbouring islands. Other coffees grown there contain caffeine as usual. Coffee, with the caffeine extracted, has also been prepared for the market. The commercial value of coffee is determined by the amount of the aromatic oil, caffeine, which develops in it by the process of roasting. By prolonged keeping it is found that the richness of any seeds in this peculiar oil is increased, and with increased aroma the coffee also yields a blander and more mellow beverage. Stored coffee loses weight at first with great rapidity, as much as 8% having been found to dissipate in the first year of keeping, 5% in the second, and 2% in the third; but such loss of weight is more than compensated by improvement in quality and consequent enhancement of value.

Coffee Roasting.—In the process of roasting, coffee seeds swell up by the liberation of gases within their substance,—their weight decreasing in proportion to the extent to which the operation is carried. Roasting also develops with the aromatic caffeine to a bitter soluble principle, and it liberates a portion of the caffeine from its combination with the caffeotannic acid. Roasting is an operation of the greatest nicety, and one, moreover, of a crucial nature, for equally by insufficient and by excessive roasting much of the aroma of the coffee is lost; and its infusion is neither agreeable to the palate nor exhilarating in its influence. The roaster must judge of the amount of heat required for the adequate roasting of different qualities, and while that is variable, the range of roasting temperature proper for individual kinds is only narrow. In continental countries it is the practice to roast in small quantities, and thus the whole charge is well under the control of the roaster; but in Britain large roasts are the rule, in dealing with which much difficulty is experienced in producing uniform torrefaction, and in stopping the process at the proper moment. The coffee-roasting apparatus is usually a malleable iron cylinder mounted to revolve over the fire on a hollow axle which allows the escape of gases generated during torrefaction. The roasting of coffee should be done as short a time as practicable before the grinding for use, and as ground coffee especially parts rapidly with its aroma, the grinding should only be done when coffee is about to be prepared.

Coffee Adulteration.—Although by microscopic, physical and chemical tests the purity of coffee can be determined with perfect certainty, yet ground coffee is subjected to many and extensive adulterations (see also ADULTERATION). Chief among the adulterant substances, if it can be so called, is chicory; but it occupies a peculiar position, since very many people on the European continent as well as in Great Britain deliberately prefer a mixture of chicory with coffee to pure coffee. Chicory is indeed destitute of the stimulant alkaloid and essential oil for which coffee is valued; but the facts that it has stood the test of prolonged and extended use, and that its infusion is, in some localities, used alone, indicate that it performs some useful function in connection with coffee, as used at least by Western communities. For one thing, it yields a copious amount of soluble matter in infusion with hot water, and thus gives a specious appearance of strength and substance to what may be really only a very weak preparation of coffee. The mixture of chicory with coffee is easily detected by the microscope, the structure of both, which they retain after torrefaction, being very characteristic and distinct. The granules of coffee, moreover, remain hard and angular when mixed with water, to which they communicate but little colour; chicory, on the other hand, swelling up and softening, yields a deep brown colour to water in which it is thrown. The specific gravity of an infusion of chicory is also much higher than that of coffee. Among the numerous other substances used to adulterate coffee are roasted and ground roots of the dandelion, carrot, parsnip and beet; beans, lupins and other leguminous seeds; wheat, rice and various cereal grains; the seeds of the broom, fenugreek and iris; acorns; "negro coffee," the seeds of *Cassia occidentalis*, the seeds of the ochro (*Hibiscus esculentus*), and also the soja or soy bean (*Glycine Soya*). Not only have these with many more similar substances been used as adulterants, but under various high-sounding names several of them have been introduced as substitutes for coffee. But also, not only is ground coffee adulterated, but such mixtures as flour, chicory and coffee, or even bran and molasses, have been

made up to simulate coffee beans and sold as such.

The leaves of the coffee tree contain caffeine in larger proportion than the seeds themselves, and their use as a substitute for tea has frequently been suggested. The leaves are actually so used in Sumatra, but being destitute of any attractive aroma such as is possessed by both tea and coffee, the infusion is not palatable. It is, moreover, not practicable to obtain both seeds and leaves from the same plant, and as the commercial demand is for the seed alone, no consideration either of profit or of any dietetic or economic advantage is likely to lead to the growth of coffee trees on account of their leaves.

(A. B. R.; W. G. F.)

Coffee Production.—The centre of production has shifted greatly since coffee first came into use in Europe. Arabia formerly supplied the world; later the West Indies and then Java took the lead, to be supplanted in turn by Brazil, whose output is of overwhelming importance. Coffee is Brazil's main industry and main export.

Brazil.—The importance of Brazil in coffee production is shown by her annual production which is about two-thirds of the world's supply. During the crop year 1926-27 the production of coffee in Brazil amounted to 21,252,000 bags of 60 kilo. each. Other countries sent to Europe and the United States 7,068,000 bags. The world's visible supply of all kinds on July 1, 1927, consisted of 4,418,000 bags of which 3,262,000 were stored in Brazil. The protection of the crop is under the control of the São Paulo institute for the permanent defence of coffee, the Federal Government having relinquished in its favour all rights conferred by law.

The law of the State of São Paulo provides that the chairman and the vice-chairman of this body shall be its ministers of Finance and of Agriculture respectively, the three remaining members of the governing body being elected by the two associations of planters and the commercial association of Santos, subject to the approval of the president of the State. The powers of the institute include the regulation of the amount of coffee to be retained in the official warehouses through which all coffee produced in the interior must pass; 10 of these had been erected throughout the coffee-growing districts of São Paulo and one in the State of Rio, their total capacity being 11,500,000 bags per annum. Other powers of the institute extend to the amount of coffee to be exported, the making of agreements with other producing countries for the protection of coffee, the concluding of financial arrangements, the levying of an export tax on coffee, and the establishment of an agricultural loan bank. To obtain funds for the institute £4,000,000 of 7½% bonds were issued in London and £1,000,000 in Holland and Switzerland in Jan. 1926. Interest on this capital is to be raised by a transport tax of one gold milreis (2s. 3d.) levied on each bag of coffee grown in and transported through the State of São Paulo.

The effects of the "permanent defence of coffee" in the United States, Brazil's greatest customer, were higher prices and reduced consumption. In June and July 1925, a mission from the United States, consisting of three representatives of the trade in coffee, visited the institute and the producing centres in Brazil. After conference, the following measures were agreed: the daily regulated entry into Santos of coffee for export in accordance with the crops and the needs of consumption; the maintenance of a stock in Santos of never less than 1,200,000 bags, to facilitate the buyers finding the qualities required; the constant attendance of American buyers on the Santos market; full publication of statistics and of data relative to crops, stocks, etc.; and the resumption of coffee-propaganda in the United States. It was also arranged that similar conferences should be held in 1926 and annually thereafter. (See BRAZIL.)

Other South American Producers.—Next in importance to Brazil as a coffee-growing country, Colombia showed signs of following her example. A law providing for the establishment of coffee bonded warehouses and the official classification of coffee, with the issue of negotiable bonds, was passed, but the declared policy of the Government was to help the industry without interfering with prices. Venezuela, Ecuador, Peru, and to a much less degree Bolivia and Paraguay also produce coffee.

West Indies.—Coffee is grown in most of the islands, often only for local use; Haiti produces the largest amount. Jamaica produces the famous Blue Mountain Coffee, which compares favourably with the best coffees of the world, and also ordinary or "plain grown."

East Africa.—Coffee growing under British auspices in Kenya has rapidly developed. In 1920 there were 27,813 ac. under coffee; on July 31, 1926, there were 68,950 ac. The production in 1926-7 was 161,498 cwt. The exports from Mombasa in 1925-6 were 143,404 cwt. valued at £771,830. The colony also had 22,888 ac. planted with trees less than three years old, which had not come into full bearing. On the London market Nairobi and Uganda coffees now appear as Kenya. Africa, of course, is the native country of the coffees and may eventually become the greatest world producer.

Arabia.—The name "Mocha" is applied generally to coffee produced in Arabia. Turkey and Egypt obtain the best grades. Traders from these countries go to Arabia, buy the crops on the trees, and supervise its picking and preparation themselves. The coffee is prepared by the "dry method."

India.—India is the principal coffee-growing region in the British empire, and exports largely to the United Kingdom. The production of coffee is restricted for the most part to a limited area in the elevated region above the south-western coast, the coffee lands of Mysore, Coorg, and the Madras districts of Malabar and the Nilgiris, comprising 86% of the whole area under the plant in India. About one-half of the whole coffee-producing area is in Mysore.

Coffee Exports.—The following table shows the exports of coffee from the principal producing countries during the last statistical year of which record is available, 1927:—

| | Lb. |
|-------------------------------|---------------|
| Brazil | 1,995,000,000 |
| Colombia | 325,638,516 |
| Venezuela | 165,000,000 |
| Dutch East Indies | 152,667,000 |
| Salvador | 110,000,000 |
| Guatemala | 96,000,000 |
| Haiti | 78,504,140 |
| Mexico | 46,836,000 |
| Nicaragua | 39,833,200 |
| Costa Rica | 35,977,000 |
| British India | 16,774,800 |
| British East Africa | 16,061,248 |
| British West Indies | 8,690,590 |

Coffee Consumption.—The annual British consumption of coffee remains stationary at about 0.7 lb. per capita. British taste in coffee is satisfied largely with the produce of the Central American Republic of Costa Rica; the demand for the produce of Kenya Colony is increasing. In Sept. 1915 the British import duty on raw coffee was increased from 14s. to 21s. per cwt. and again to 42s. in 1916. On Sept. 1, 1919 the duties became 42s. on foreign grown, and 35s. on that from British possessions. Later changes were: in 1922, 28s. and 23s. 4d.; and in 1924, 14s. and 11s. 8d.

Annual consumption in the United States rose from 11 lb. *per capita* before the World War to 12.4 lb. in 1923; in 1925 it had fallen to 11.09 lb. About two thirds of the imports in 1925 came from Brazil and the greater part of the remainder from Colombia.

(C. L. T. B.)

COFFEE, PREPARATION OF. The essentials of coffee-making are: freshly roasted coffee (high roast is undesirable); coffee ground to the size of granulated sugar; scrupulous cleanliness and care of the coffee itself and every container and coffee pot used in connection with it; freshly boiled water; accuracy in measurement of water, coffee and the time of cooking. Coffee is sensitive to contamination. Strong odours affect it and unless it is cared for, coffee instead of being coffee, will taste of cheese, kerosene or even the mixture of odours we breathe on entering a grocery or drug store. In some parts of Europe coffee is subjected to what is called a high roast; that is to say it is roasted until the berry is almost black and consequently its real flavour is lost and an acrid, pungent taste results. In America according to locality and the demand of the public, these roasts are variously described and used; cinnamon. civt.

medium and dark roasts, with the result that a full, blended flavour of the coffee itself is obtained. The next and almost greatest essential is the way the coffee is ground. No matter how well roasted or how fresh your coffee, unless it is ground correctly you cannot have a cup of good coffee. To obtain the best and most economical results, grind your coffee to the size of fine granulated sugar. If it is coarser than this, the cooking process whatever it be, will fail to secure the best results. If it is powdered, it will cake, the water cannot flow freely and a weak and unattractive drink will result.

There are two popular methods of making coffee. The old-fashioned so-called "boiling process" is still used and approved of. Coffee should never really be boiled. The so-called "boiling process" is as follows: Allow one dessert-spoon of finely ground coffee to each coffee cup full of boiling water. Mix the coffee with the white and shell of an egg in the coffee pot. Pour in the boiling water. Let it stand on the back of the stove for five minutes where it will steep, not boil. Pour a scant half cupful of cold water down the spout. Let it stand again for a few minutes, two or three, till the cold water has had time to heat. Pour through a sieve into the serving coffee pot and you have a delicious drink. But this process is capable of an infinite variety of dangers. You may forget and leave it on that part of the stove where the fire is hottest and the mixture will boil and become bitter. The egg may not be fresh. The pot may not be clean, and being busy with other things you may leave it on the stove 20 instead of 10 minutes. Any of these accidents will ruin the morning cup and perhaps the day's enjoyment into the bargain.

Because uniformity of time and quantity of coffee and water are essential, the percolating process is best. It is almost fool-proof and a uniform drink may be obtained.

To percolate coffee, fill the pot with cold water, enough to cover the spout on the inside of the pot. Fill the cup full to the inside rim with finely-ground coffee, covering the tube with your finger while doing so. Put on the spreader plate. Percolate for at least 15 minutes. The longer the pumping continues the stronger the coffee. For breakfast coffee, use a dessert-spoon of finely ground coffee to a cup. For after-dinner coffee decrease the quantity of water. All the above rules should be adjusted to personal taste. Never use boiling water. Remember that cleanliness is next to godliness and invest everything that you use in connection with coffee with a god-like cleanliness.

The third process is the filtering process where a cup of aluminium fits into a glass receptacle. A piece of filter paper is placed on the bottom of the cup. The proportion of coffee to water is the same and the finely pulverized coffee is placed in the cup, then boiling water poured through. This obviates any danger of bitterness and acidity but is not quite so satisfactory except when used in hotels and restaurants where urns made specially for the purpose ensure the coffee's always being hot. If a filtrator is used in a home, an attempt should be made to let the water pass twice through the pulverized coffee.

There is still another method called the filtrating process. This is very good, being simple, and gives a delicious beverage, but it is a little troublesome because as the machine is made entirely of glass, care must be used lest the bowl or funnel break.

Purchase a glass filtrator. Place the pulverized coffee in the funnel. Fill the bowl with boiling water. Light the alcohol lamp and place it under the bowl on its own stand. Almost instantly the water rises through the coffee into the funnel. Always leave some water in the bowl, about a couple of table-spoons. Remove the lamp. The water immediately returns to the bowl and hence delicious, exhilarating coffee is ready.

(A. F. MACD.)

COFFEE-BERRY (*Rhamnus californicus*), a North American shrub of the buckthorn family (Rhamnaceae), called also pigeon-berry and *yerba del oso*, native to canyons and mountain slopes in California. It grows usually about 5 ft. high, bears oblong, finely toothed, pointed leaves; small, greenish flowers, and a round berry, black when ripe, containing usually two somewhat coffee-like nutlets. (See BUCKTHORN; CASCARA SAGRADA.)

COFFER, in architecture, a sunk panel in a ceiling or vault; also a casket or chest in which jewels or precious goods are kept, and, if of large dimensions, clothes. The marriage coffers in Italy were often richly carved and gilded, and sometimes painted by great artists. (See CHEST.)

COFFER-DAM, a dam formed to enable foundations to be laid in a site which is under water. The engineer surrounds the site with an embankment in such fashion as to form an enclosure from which the water is excluded. Where the depth of water is small and the current slight, simple clay dams may be used, but in general coffer-dams consist of two rows of piles, the space between which is packed with clay puddle. The dam must be sufficiently strong to withstand the exterior pressure to which it is exposed when the enclosed space is pumped dry. See DAM.

COFFEYVILLE, a city of Montgomery county, in south-eastern Kansas, U.S.A., on the Verdigris river, near the southern boundary of the State. It is on Federal highway 166, and is served by the Missouri Pacific, the Santa Fe, the Missouri-Kansas-Texas, and the Union Traction (electric) railways. The population in 1925 (State census) was 16,229; and was 16,198 in 1930. It is in the mid-continent gas and oil field and the Kansas coal-field; is a railway division point and an important grain centre; and has oil refineries, zinc smelters, flour and meal mills, tile and vitrified brickworks, tank-car factories, wagon and carriage factories and other industries. The aggregate output of its factories in 1925 was valued at \$16,927,557.

Coffeyville was founded in 1869 and incorporated in 1872. It was named after A. M. Coffey, an important citizen in the early days of the territory. After the railway came through it became a shipping point for cattle from Texas and Indian Territory and a trade centre for a wide area. Natural gas was discovered in 1892.

COFFIN, the receptacle in which a corpse is confined (Lat. *cophinus*, a coffer, chest or basket, but not "coffin" in its present sense). The Greeks and Romans disposed of their dead both by burial and by cremation. Greek coffins varied in shape, being in the form of an urn, or like the modern coffins, or triangular, the body being in a sitting posture. The material used was generally burnt clay, and in some cases this had obviously been first moulded round the body, and so baked. In the Christian era, stone coffins came into use. Examples of these have been frequently dug up in England. Those of the Romans who were rich enough had their coffins made of a limestone brought from Assos in Troas,

FROM THE SMITHSONIAN BUREAU OF ETHNOLOGY REPORT

CANOE BURIAL, FORMERLY PRACTICED AMONG AMERICAN INDIAN TRIBES
The corpse, wrapped in skins or other covering, was laid in a canoe and placed on a wooden scaffold, where it remained for a certain period while mourners kept watch below. Sometimes the canoe coffin was set afloat on the water, to be carried in the direction of the current

which it was commonly believed "ate the body"; hence arose the name sarcophagus (*q.v.*).

The coffins of the Chaldaeans were generally clay urns with the top left open, resembling immense jars, moulded round the body, as the size of the mouth would not admit of its introduction after the clay was baked. The Egyptian coffins, or sarcophagi, as they have been improperly called, are the largest stone coffins known and are generally highly polished and covered with hieroglyphics, usually a history of the deceased. Mummy chests shaped to the form of the body were also used, being made of hard wood or

papier mâché painted, and bore hieroglyphics. Unhewn flat stones were sometimes used by early European peoples to line the grave. One was placed at the bottom, others stood on their edges to form the sides, and a large slab was put on top, thus forming a rude cist. In England after the Roman invasion these rude cists gave place to the stone coffin which was used until the 16th century.

Primitive wooden coffins were formed of a tree-trunk split down the centre, and hollowed out—a type still in use among peoples in

A MUMMY CHEST COVERED WITH STUCCO. XVII-XVIII DYNASTY

This type of coffin, shaped in the form of the body of the deceased, was favoured by less wealthy Egyptians. The example above was excavated at Thebes

the lower culture. The earliest specimen of this type is in the Copenhagen museum, the implements found in it proving that it belonged to the Bronze Age. This type of coffin, more or less modified by planing, was used in mediaeval Britain by those who could not afford stone, while the poor were buried without coffins, wrapped simply in cloth or even covered only with hay and flowers. Towards the end of the 17th century, coffins became usual for all classes.

Among the American Indians some tribes, *e.g.*, the Sacs, Foxes and Sioux, used rough hewn wooden coffins; others, such as the Seris, sometimes enclosed the corpse between the carapace and plastron of a turtle. The Seminoles of Florida used no coffins, while at Santa Barbara, California, canoes containing corpses have been found buried, though they may have been intended for the dead warrior's use in the next world. Rough stone cists, too,

A SCULPTURED ROMAN SARCOPHAGUS FOUND AT TARSUS

In the resemblance of this lid to the roof of a house, is preserved the original idea of the coffin as a dwelling-place for the dead. Since the Roman coffin was usually placed against a wall inside a tomb, the back is generally free of decoration

have been found in Illinois and Kentucky. In their tree and scaffold burial the Indians sometimes used wooden coffins or travois baskets, or the bodies were simply wrapped in blankets. Canoes, mounted on a scaffold, near a river, were used as coffins by some tribes; while others placed the corpse in a canoe or wicker basket and floated it out into the stream or lake. The aborigines of Australia generally used coffins of bark, but some tribes employed baskets of wicker-work.

Lead coffins were used in Europe in the middle ages, shaped like

the mummy chests of ancient Egypt. Iron coffins were certainly used in England and Scotland as late as the 17th century. The coffins used in England to-day are generally hexagonal in shape, of elm or oak lined with lead, or with a leaden shell. In America glass is sometimes used for the lids, and the inside is lined with copper or zinc. The coffins of France and Germany and the Continent in general usually have sides and ends parallel. Coffins used in cremation throughout the civilized world are of some light material easily consumed and yielding little ash. Ordinary thin deal and *papier mâché* are the favourite materials. Coffins for what is known as Earth to Earth Burial are made of wicker-work covered with a thin layer of *papier mâché* over cloth.

COG. (1) A broadly built, round-shaped ship, used as a trader and also as a ship of war till the 15th century (M.E. *cogge*, cf. O.Fr. *cogue*, from which "cock-boat" is derived). (2) A tooth in a series of teeth, on the circumference of a wheel, which works with the tooth in a corresponding series on another wheel (see *MECHANICS*). (3) A slang term for a form of cheating at dice.

COGERS' HALL, a London tavern debating society. Instituted in 1755 at the White Bear Inn, Fleet street, and moved about 1850 to Shoe lane; in 1871 it migrated to the Barley Mow Inn, Salisbury square, E.C., and has since moved to the Cannon Inn, Cannon street, E.C. The accepted derivation is from Descartes' *Cogito, ergo sum*, "The Society of Thinkers." The aims of the Cogers were "the promotion of the liberty of the subject and the freedom of the press, the maintenance of loyalty to the laws, the rights and claims of humanity and the practice of public and private virtue." Among its early members Cogers' Hall reckoned John Wilkes, one of its first presidents, and Curran. Later Dickens was a prominent member.

See Peter Rayleigh, *History of Ye Ancient Society of Cogers* (1904).

COGHLAN, SIR TIMOTHY AUGUSTUS (1856-1926), Australian civil servant, second son of Thomas Coghlan, an Irish Roman Catholic, was born in Sydney and educated at Sydney Grammar School. He went into Government service in 1873, in the Public Works Department, and in 1884 became assistant engineer of harbours and rivers. In 1885 he was appointed head of the newly-created department of statistics, and was responsible for the preparation of much valuable material, including a full statistical register of trade and commerce in New South Wales. His most important work is the *History of Labour and Industry in Australia* (4 vols. 1918). He also published: *Wealth and Progress of New South Wales* (1887); *Statistical Account of Australia and New Zealand* (1891); *Progress of Australia in the 19th century*, in collaboration with the Hon. T. T. Ewing (1903).

From 1905 to 1915 he held the post of Agent-General for New South Wales, and was knighted in 1914. He was re-appointed from 1916-17, 1920-25, and again on the resignation of Sir Arthur Cocks. With Sir Joseph Cook he represented Australia on the Pacific Cable Board, and he held various public appointments in New South Wales (Chairman of Board of Old Age Pensions, etc.), serving also on several Royal Commissions. He took a great interest in vital statistics, and was in charge of the census in New South Wales in 1891 and 1901. He died on April 30, 1926.

COGHLAN, CHARLES FRANCIS (1841-1899), Irish actor, was born in Paris, and made his first London appearance in 1860. He went to America in 1876, where he remained for the rest of his life, playing first in Augustin Daly's company and then in the Union Square stock company, during the long run of *The Celebrated Case*. He also played with his sister, and in support of Mrs. Langtry and Mrs. Fiske, and in 1898 produced a version of Dumas' *Kean*, called *The Royal Box*, in which he starred during the last years of his life. He died in Galveston (Texas), on Nov. 27, 1899.

His sister, the actress ROSE COGHLAN (1853-), went to

America in 1871, was again in England from 1873 to 1877, playing with Barry Sullivan, and then returned to America, where she became prominent as Countess Zicka in *Diplomacy*, and Stephanie in *Forget-me-not*. She was at Wallack's almost continuously until 1888, and subsequently appeared in melodrama in parts like the title-rôle of *The Sporting Duchess*.

COGNAC, a town of south-western France, capital of an *arrondissement* in the department of Charente, on the left bank of the river Charente, 23 m. W.N.W. of Angoulême. Pop. (1926) 16,505. The streets of the old town are very narrow, but the newer parts have open spaces such as the Parc François I^{er} overlooking the Charente. In 1526 Cognac gave its name to a treaty concluded against Charles V. by Francis I., the pope, Venice and Milan. Its possession was contested during the wars of religion, and in 1570 it became one of the Huguenot strongholds. In 1651 it successfully sustained a siege against Louis II., prince of Condé, leader of the Fronde. The 12th century church of St. Leger preserves a fine Romanesque façade and a tower of the 15th century. A castle of the 15th and 16th centuries, once the residence of the counts of Angoulême, and a mediaeval gate stand in the older part of the town. Cognac is the seat of a subprefect and has tribunals of first instance and of commerce, a council of trade arbitrators, and a chamber of commerce. Its most important industry is the distillation of the brandy (*q.v.*) to which the town gives its name. Large quantities are carried, by way of the river, to the neighbouring port of Tonnay-Charente. The industries subsidiary to the brandy trade, such as the making of cases and bottles, occupy many hands. A considerable trade is maintained in grain and cattle. (See also BRANDY.)

COGNE, a village, province of Aosta, Italy, from which town it is 16m. due south by road (9m. direct). Pop. (1921) 575 (of commune, 1,625). It lies at the northern foot of the Gran Paradiso and is a favourite summer resort. Victor Emanuel II. formed a shooting reserve here for wild goat and chamois. The important iron mines belonging to the Ansaldo company lie east of the village, and a newly installed electric plant dealt with 5,800 tons of pig iron in 1925.

COGNITION means "knowing," in the widest sense of the term. In psychology it is used to denote one of the three ultimate functions or processes of consciousness, the other being feeling and conation (or willing). Cognition includes every mental process that can be described as an experience of knowing as distinguished from an experience of feeling or of willing; it includes, in short, all process of consciousness by which knowledge is built up. In its most familiar and fully developed form it is known as judgment, in which a certain object (known logically and grammatically as a "subject") is discriminated from other objects and characterized by some concept or concepts. Although cognition is readily distinguishable from feeling and conation, yet in the actual flow of mental life the three types of experience are always found together, not separate, but one of them is usually predominant in one total experience, another in another, and this fact facilitates their mutual discrimination. Psychology, as a descriptive science, is not concerned with the epistemological question, how external objects can be revealed in subjective experiences; it simply takes at their face value these cognitive experiences in which objects appear to be known somehow, and leaves the critical problems to epistemology and logic.

See PSYCHOLOGY, and THEORY OF KNOWLEDGE, and authorities there quoted.

COGNIZANCE, knowledge, notice, especially judicial notice, the right of trying or considering a case judicially, the exercise of jurisdiction by a court of law. In heraldry a "cognizance" is an emblem, badge or device, used as a distinguishing mark by the body of retainers of a royal or noble house.

COHAN, GEORGE MICHAEL (1878–), American actor, author, and producer, was born in Providence (R.I.), July 4 1878. His parents were of the theatrical profession, and at an early age he appeared with them in juvenile parts, subsequently taking comedy rôles in vaudeville and on the legitimate stage. Also at an early age he began writing plays and popular songs.

A vivid description of his early experiments and the stage career of the "Four Cohans" is given in his autobiography, *Twenty Years on Broadway and the Years it Took to Get There* (1925). He has written and produced many plays and musical revues, in the majority of which he also acted.

Among his productions may be mentioned *The Governor's Son* (1901); *Forty-five Minutes From Broadway* (1905); *The Talk of New York* (1907); *Get-Rich-Quick Wallingford* (1910); *Broadway Jones* (1912); *Seven Keys to Baldpate* (1913); musical revues in 1914, 1915, and 1916; *The Tavern* (1920); *The Song-and-Dance Man* (1923); *American Born* (1925). In addition he wrote numerous musical numbers. One of his songs, *Over There*, had an international vogue during the World War.

COHEN (Hebrew for "priest"), a Jewish family name, implying descent from Aaron and the Hebrew priests (*Cohanim*). Many families claiming such descent are, however, not named Cohen. Other forms of the name are Cohn, Cowen, Kahn, Kogan, etc.

See J. Jacobs, *Jewish Encyclopaedia*, iv. 144. For Cohen=*Episcopus*, see H. P. Stokes, *Stud. in Anglo-Jew. Hist.*, 1913, p. 18: for variations of Cohen, see A. M. Hyamson, *Jew. Lit. Annual* (for 1903), 1904, p. 70.

COHEN, ERNST JULIUS (1869–), Dutch chemist, was born at Amsterdam on March 7, 1869. He studied chemistry under Arrhenius at Stockholm, Moissan at Paris, and Van t'Hoff at Amsterdam; he became assistant to the latter in the university chemical laboratories at Amsterdam in 1893 and in 1902 he was appointed professor of physical chemistry at the University of Utrecht.

Cohen's most important work is on the allotropy of metals, and particularly of tin; this was published mainly in the periods 1900–02 and 1911–12. He is the author of a large number of papers on physical and electro-chemistry, and his piezo-chemical studies are important. His papers are published chiefly in the Dutch and German scientific journals.

Cohen has also written *Studies in Chemical Dynamics after Van t'Hoff* (1896), *Physical Chemistry for Biologists*, *Inorganic Chemistry for Medical Students* (1907), and *Jacobus, Henricus Van t'Hoff, his Life and Work* (1912). Cohen is a foreign member of the Royal Society of London.

COHERER, a device by means of which a feeble oscillating electric current may be detected by a galvanometer (*q.v.*) or telephone (*q.v.*), the essential characteristics being that the current through the coherer is concentrated at a point and that the resistance (see RESISTANCE, MEASUREMENT OF) of the material has a negative temperature coefficient (*q.v.*) so that the coherer is self-restoring. A simple form of coherer consists of an oxidized iron plate against which rests the point of a steel needle. (See TELEPHONY.)

COHESION: see SOLID STATE, THEORY OF.

COHN, FERDINAND JULIUS (1828–1898), German botanist, was born on the 24th of January 1828 at Breslau. He was educated at Breslau and Berlin, and in 1859 became extraordinary, and in 1871 ordinary, professor of botany at Breslau University. He was contemporary with N. Pringsheim, and worked with H. R. Goeppert, C. G. Nees von Esenbeck, C. G. Ehrenberg and Johannes Müller. He made remarkable advances in the establishment of an improved cell-theory, discovered the cilia in, and analysed the movements of, zoospores, and pointed out that the protoplasm of the plant-cell and the sarcode of the zoologists were one and the same physical vehicle of life. Although these early researches were especially on the Algae, in which group he instituted marked reforms of the rigid system due to F. T. Kützinger, Cohn studied such varied subjects as *Aldorovanda*, torsion in trees, the nature of waterspouts, the effects of lightning, physiology of seeds, the proteid crystals in the potato, which he discovered, formation of travertine, the rotatoria, and luminous worms.

It is, however, in the introduction of the strict biological and philosophical analysis of the life-histories of the lower and most minute forms of life that Cohn's greatest achievements consist, for he applied to these organisms the principle that we can only know the phases of growth of microscopic plants by watching every stage of development under the microscope, just as we

learn how different are the youthful and adult appearances of an oak or a fern by direct observation. His account of the life-histories of *Protococcus* (1850), *Stephanosphaera* (1852), *Volvox* (1856 and 1875), *Hydrodictyon* (1861), and *Spaeroplea* (1855-1857) among the Algae have never been put aside. The first is a model of what a study in development should be; the last shares with G. Thuret's studies on *Fucus* and Pringsheim's on *Vaucheria* the merit of establishing the existence of a sexual process in Algae. Among the Fungi Cohn contributed important researches on *Pilobolus* (1851), *Empusa* (1855), *Tarichium* (1869), as well as valuable work on the nature of parasitism of Algae and Fungi.

Cohn may be said to have founded the science of bacteriology. He seems to have been always attracted particularly by curious problems of fermentation and coloration due to the most minute forms of life, as evinced by his papers on *Monas prodigiosa* (1850) and "Über blutähnliche Färbungen" (1850), on infusoria (1851 and 1852), on organisms in drinking-water (1853), "Die Wunder des Blutes" (1854), and had already published several works on insect epidemics (1869-1870) and on plant diseases, when his first specially bacteriological memoir (*Crenothrix*) appeared in the journal, *Beiträge zur Biologie*, which he then started (1870-71), and which has since become so renowned. Investigations on other branches of bacteriology soon followed, among which "Organismen der Pockenlymphe" (1872) and "Untersuchungen über Bacterien" (1872-1875) are most important, and laid the foundations of the science. Cohn brought out and helped R. Koch in publishing his celebrated paper on *Anthrax* (1876), the first clearly worked out case of a bacterial disease.

Among his most striking discoveries may be mentioned the nature of Zoogloea, the formation and germination of true spores—which he observed for the first time, and which he himself discovered in *Bacillus subtilis*—and their resistance to high temperatures, and the bearing of this on the fallacious experiments supposed to support abiogenesis; as well as works on the bacteria of air and water, the significance of the bright sulphur granules in sulphur bacteria, and of the iron oxide deposited in the walls of *Crenothrix*. His discoveries in these and in other departments attest his acute observation and reasoning powers. Cohn had clear perceptions of the important bearings of Mycology and Bacteriology in infective diseases, as shown by his studies in insect-killing fungi, microscopic analysis of water, etc. He was a foreign member of the Royal Society and of the Linnean Society, and received the gold medal of the latter in 1895. He died at Breslau on June 25, 1898.

Lists of his papers will be found in the *Catalogue of Scientific Papers of the Royal Society*, and in *Ber. d. d. bot. Gesellsch.*, vol. xvii. p. 196 (1899); see also P. Cohn, *Ferdinand Cohn*, with Life by F. Rosen.

COHN, GUSTAV (1840-1918), German economist, born on Dec. 12, 1840, at Marienwerder, West Prussia, was educated at Berlin and Jena and became professor of political science first at Zurich (1875), and then at Göttingen (1884). He died at Göttingen on Sept. 20, 1918. His principal works are:

Untersuchungen über die englische Eisenbahnpolitik (Leipzig, 1874-75); *System der Nationalökonomie* (Stuttgart, 1885); *Finanzwissenschaft* (1889); *Nationalökonomische Studien* (1886), and *Zur Geschichte und Politik des Verkehrswesens* (1900).

COHNHEIM, JULIUS (1839-1884), German physiologist, was born at Demmin on July 20, 1839, and died on Aug. 15, 1884 at Leipzig. After serving as an army surgeon in 1864-65 he became an assistant in the Pathological institute in Berlin and was the most distinguished of Virchow's pupils. He was subsequently professor of pathology at Kiel (1868), Breslau (1872) and Leipzig (1876), where he was also director of the Pathological institute. He was a brilliant teacher, and Ehrlich was among his pupils at Breslau. His first important dissertation on inflammation of serous membranes appeared in 1861, and was followed by other important papers on that subject from 1869 to 1873. On this question his teaching was opposed to that of Virchow. He showed that inflammation is due to the passage of white corpuscles through the walls of the capillaries and that pus is formed largely

of these corpuscles in a disintegrated state. Cohnheim made many useful innovations in the method of microscopical work. His most important book is his *Vorlesungen über allgemeine Pathologie* (2nd ed. 1882).

COHOES, a manufacturing city of Albany county, New York, U.S.A., 9m. N. of Albany, on the Hudson river at the mouth of the Mohawk. It is served by the Delaware and Hudson and the New York Central railways, and by the State barge canal. The population in 1920 was 22,987 (22.9% foreign-born white), and was 23,226 in 1930 by the Federal census. The output of its factories was valued in 1925 at \$19,898,399. Water-power from the falls of the Mohawk (75ft. high and 900ft. across) is supplemented by a hydro-electric plant developing 54,000 horsepower. Chief among the many manufactures are cotton and woollen knit goods, cotton fabrics, collars and shirts, machinery, wall-paper and tractors. Cohoes was part of the manorial grant made to Killian van Rensselaer, and probably it was settled soon after 1629. It was incorporated as a village in 1848 and as a city in 1869. The van Schaick manor house was the headquarters of Gen. Schuyler during part of the Revolutionary War. The old colonial military road from Albany to Ft. Edward and Lake George runs through the city.

COHORT (Lat. *cohors*), originally a place enclosed; in the Roman army, the name of a unit of infantry. The troops of the first grade, the legions, were divided into cohorts, of which there were ten in each legion: the cohort thus contained 600 men. Among the troops of the second grade (the *auxilia*) the cohorts were independent foot regiments 500 or 1,000 strong, corresponding to the *alae*, which were similar regiments of cavalry; they were generally posted on the frontiers of the empire in small forts of four to eight acres, each holding one cohort or *ala*. The special troops of Rome itself, the Praetorian Guard, the *Urbanæ Cohortes*, and the *Vigiles* (fire brigade), were divided into cohorts (see further ROMAN ARMY). The phrase *cohors praetoria* or *cohors amicorum* was sometimes used, especially during the Roman republic, to denote the suite of the governor of a province; hence developed the Praetorian cohorts which formed the emperor's bodyguard.

In biology, "cohort" is a term for a group of allied orders or families of plants or animals.

See J. E. Sandys, *Companion to Latin Studies* (1921), sections 380, 463, 714 et seq., 723-4, 728, 730, 773, 1089.

COIF, a close-fitting covering for the head. Originally it was the name given to a head-covering worn in the middle ages, tied like a night-cap under the chin, and worn out of doors by both sexes; this was later worn by men as a kind of night-cap or skull-cap. The coif was also a close-fitting cap of white lawn or silk, worn by English sergeants-at-law as a distinguishing mark of their profession (see SERGEANT-AT-LAW).

COIMBATORE, city and district, British India, in the Madras presidency. The city is situated on the left bank of the Noyil river, 305 m. from Madras by the South Indian railway. In 1921 it had a population of 65,788. The city stands 1,437 ft. above sea-level, is healthy, and is rendered additionally attractive to European residents by its picturesque position on the slopes of the Nilgiri hills. The famous temple of Perur lies 3 m. E. of Coimbatore. Coimbatore is an important industrial centre, carrying on cotton weaving and spinning, tanning and the manufacture of coffee, sugar, manure and saltpetre. It has two second-grade colleges, a college of agriculture, training and industrial schools, and a school of forestry.

THE DISTRICT OF COIMBATORE has an area of 7,225 sq. miles. It is a flat, open country, hemmed in by mountains on the north, west and south, but opening eastwards on to the great plain of the Carnatic; the average height of the plain above sea-level is about 900 ft. The principal mountains are the Anamalai hills, in the south of the district, rising at places to a height of between 8,000 and 9,000 ft. In the west the Palghat and Vallagiri hills form a connecting link between the Anamalai range and the Nilgiris, with the exception of a remarkable gap known as the Palghat pass. This gap, which completely intersects the Ghats, is about 20 m. wide. In the north the Cauvery chain extends

eastwards from the Nilgiris, and rises in places to 4,000 ft. The principal rivers are the Cauvery, Bhavani, Noyil and Amravati. There are numerous canals, wells and tanks for irrigation. Coimbatore district was acquired by the British in 1799 at the close of the war which ended with the death of Tippoo. In 1921 the population was 2,219,848. The principal crops are millet, rice, other food grains, pulse, oilseeds, cotton and tobacco, and raw silk is produced. Forests, yielding valuable timber, cover a large area. There are cotton mills and factories for pressing cotton, preparing coffee, making soap and dyeing. The south-west line of the Madras railway runs through the district and the South Indian railway (of metre gauge) joins this at Erode.

COIMBRA, Portuguese city on the north bank of the river Mondego, 115m. N.N.E. of Lisbon, on the Lisbon-Oporto railway. Pop. (1925), 20,841. Coimbra derives its present importance from the fact that it is the seat of the only university in the kingdom—an institution which was originally established at Lisbon in 1291, was transferred to Coimbra in 1306, was again removed to Lisbon, and was finally fixed at Coimbra in 1537. There are five faculties—theology, law, medicine, mathematics and philosophy. The library contains about 150,000 volumes, and the museums and laboratories are on an extensive scale. Among the other educational establishments are a military college, a royal college of arts, a scientific and literary institute and an episcopal seminary.

The city, picturesquely situated on a hill above the river, is the seat of a bishop, suffragan to the archbishop of Braga; its new cathedral, founded in 1580, is of little interest, but the old one is a fine specimen of 12th-century Romanesque, and retains portions of the mosque which it replaced. The principal churches are Santa Cruz, of the 16th century, and San Salvador, founded in 1169. On the banks of the Mondego stand the ruins of the once splendid monastery of Santa Clara, established in 1286; and the celebrated *Quinta das Lagrimas*, where Inez de Castro (q.v.) is believed to have been murdered in 1355.

A Latin inscription of the fourth century identifies Coimbra with the ancient Aeminium; while Condeixa, 8m. S.S.W., represents the ancient Conimbriga or Conembrica. In the ninth century, however, when the bishopric of Conimbriga was removed hither, its old title was transferred to the new see, and hence arose the modern name Coimbra. The city was for a long time a Moorish stronghold, but in 1064 it was captured by Ferdinand I. of Castile and the Cid. Until 1260 it was the capital of the country, and no fewer than six kings—Sancho I. and II., Alphonso II. and III., Pedro and Ferdinand—were born within its walls. It was also the birthplace of the poet Francisco Sá de Miranda (1495–1558), and, according to one tradition, of the more famous Luís de Camoens (1524–1580), who was a student at the university between 1537 and 1545. In 1755 Coimbra suffered considerably from the earthquake. In 1810 it was sacked by the French under Marshal Masséna. In 1834 Dom Miguel made the city his headquarters; and in 1846 it was the scene of a Miguelist insurrection. The administrative district of Coimbra coincides with the southwestern part of Beira; pop. (1920), 353,121; area 1,508 sq.m.

COÍN, a town of southern Spain, in the province of Málaga, 18m. by rail W.S.W. of Málaga. Pop. (1920) 11,632. Coín, on the north slope of the Sierra de Mijas, is the centre of a rich agricultural district. It exports large quantities of oranges, lemons, grapes and raisins, and marble from neighbouring quarries.

COIN. This is properly the term for a wedge-shaped die used for stamping money, and so transferred to the money so stamped; hence a piece of money. The form "quoin" is used for the external angle of a building (see **QUOINS**), and "coign," also a projecting angle, survives in the Shakespearean phrase "a coign of vantage." The older forms of the word are *coyne*, *quoim* and *coign*, all derived from the Lat. *cuneus*, a wedge, through the O.Fr. *coing* and *cuingne*.

COINAGE OFFENCES. The coinage of money is in all States a prerogative of the Sovereign power; consequently any infringement of that prerogative is always severely punished, as being an offence likely to interfere with the well-being of the

State, and in fact was at one time high treason in Great Britain.

The statute law against offences relating to the coin was codified by the Coinage Offences Act, 1861 [England] which provides that whoever falsely makes or counterfeits any coin resembling or apparently intended to resemble or pass for any current gold or silver coin of the realm, or gilds, silvers, washes, cases over or colours with materials capable of producing the appearance of gold or silver a coin or a piece of any metal or mixture of metals, or files or alters it, with intent to make it resemble or pass for any current gold or silver coin, or who buys, sells, receives or pays a false gold or silver coin at a lower rate than its denomination imports, or who receives into Great Britain any false coin knowing it to be counterfeit, or who, without lawful authority or excuse, knowingly makes or mends, buy or sells, or has in his custody or possession, or conveys out of the Royal Mint any coining moulds, machines or tools, is guilty of felony. The punishment for such offences is either penal servitude for life or for not less than three years, or imprisonment for not more than two years, with or without hard labour. Whoever impairs, diminishes or lightens current gold or silver coin, with intent to pass same, is liable to penal servitude for 14 years, and whoever has in his possession filings or clippings obtained by impairing or lightening current coin is liable to penal servitude for seven years. The statute also makes provision against tendering or uttering false gold or silver coin, which is a misdemeanour, punishable by imprisonment with or without hard labour. Provision is also made with respect to falsely making, counterfeiting, tendering or uttering copper coin, exporting false coin, or defacing current coin by stamping names or words on it, and counterfeiting, tendering or uttering coin resembling or meant to pass as that of some foreign state. The Act of 1861 applies to offences with respect to colonial coins as well as to those of Great Britain. Making or selling medals or coins resembling current coin is made a misdemeanour by the Counterfeit Medal Act, 1883.

Counterfeiting in the United States is punishable under both Federal and State laws. Congress, under its Constitutional power to punish counterfeiting, has legislated against those who counterfeit the coin, currency and securities of the Government, or attempt to pass as valid such as have been counterfeited by others. Under its power to define and punish offenses of international law and its power to control interstate and foreign commerce, it also has legislated against the counterfeiting in the United States of foreign governmental, bank and corporation coins and securities.

State laws have been passed in all of the states penalizing the counterfeiters of state and other securities within the state, or the attempt to pass as valid such as have been counterfeited by others.

COIR, the outer covering of the husk of the coco-nut; an exceedingly strong fibrous material which has many uses in industry, notably in the manufacture of coarse mats and brushes. The name is from the Malay *Kāyar*, cord, *Kāyaru*, to be twisted. Very large quantities of coir are exported from the Pacific, and there is a considerable market in England, the imports and re-exports reaching big figures. In 1926 the imports into the United Kingdom of coir yarn amounted to 425,881 tons, besides a considerable quantity, not separately stated, of coir fibre.

COIRE: see **CHUR**.

COKE, **SIR EDWARD** (1552–1634), English judge, was born at Mileham in Norfolk on Feb. 1, 1552. He was educated at Norwich Grammar School and Trinity College, Cambridge, and in 1572 entered the Inner Temple. He was called to the bar in 1578, and the next year was chosen reader of Lyon's Inn, a responsible position usually held by counsel of ten years' standing. His early cases included the Cromwell libel case (4 Rep. 13) and *Shelley's Case* (1 Rep. 94), and his reputation became great. In 1582 he married Bridget Paston, who brought him a fortune. In 1589 he became M.P. for Aldeburgh, and in 1592 solicitor-general, recorder of London and Speaker of the House of Commons, a post that involved difficulties with Elizabeth over the Commons' passion for discussing ecclesiastical matters.

In 1594 he first crossed Bacon's course. The attorney-generalship fell vacant, and Bacon, supported by Essex, became his rival for the post. Coke got it, and then kept Bacon out of the solicitorship as well, or so Bacon thought. Coke's wife died in 1598 and six months later he married Lady Elizabeth Hatton, Bacon again being his unsuccessful rival.

As attorney-general, Coke was busy. He started a series of State prosecutions for libel on a large scale. The theory he advocated was that all comment on the doings of authority was unjustified; the remedy of those aggrieved was to be sought in the courts or in parliament. He also had the conduct of several of the great trials of the day. In 1600—the year in which the first volume of his *Reports* appeared—he prosecuted Essex and Southampton, in 1603 Raleigh, and in 1605 the Gunpowder Plot conspirators. (See Cobbett, *State Trials*, vol. ii.)

In 1606 Coke was made chief justice of the common pleas, and there began at once that series of conflicts which eventually broke his career. At the time of his appointment archbishop Bancroft had already started his attempt to shake off the control which the common law courts exercised by prohibition, and James, as ever, was ready to support any cause that looked likely to break the supremacy of the common law. This matter came to a head in 1607, when, on Bancroft renewing his protests, James took up the position that, as fountain of justice, he could remove any cases he pleased from his judges and try them himself. Coke refuted him, in spite of some precedents under the early kings that must have been difficult to get round. But the disputes with the ecclesiastical courts went on. In 1610 Coke gave his celebrated opinion before the Council that the King's proclamation cannot change the law, and in 1611, he had a brush with the court of high commission, with the result that the next year he was put on the commission himself; Coke evaded this attempt to muzzle him by finding legal flaws in the commission's appointment. In 1613 Bacon, with an eye to his own advancement, and to get Coke into a position where he would be less troublesome, had him "promoted" to be chief justice of the king's bench, an office of higher dignity and less salary. Coke was made a privy councillor, and was the first to be called Lord Chief Justice of England, which was remembered against him afterwards. Here his pre-eminence was still as great; and he had to protest, in *Peacham's Case*, against the practice of consulting the judges privately, which James, abetted by Bacon, was more or less driven to follow because when the whole Bench was consulted together the rest of the judges merely echoed Coke. In 1615, still an implacable and bigoted adherent of the common law, he tried his strength too high. The Court of King's Bench started a dispute with the chancery over the right of the chancellor to interfere where a common law court had given a decision, and Coke was believed to be at the bottom of the attempt to make some who had been suitors in a case of this sort liable to the penalties of a *praemunire*, an attempt which failed. The disputes continued, embittered by Coke's personal dislike for Egerton, the chancellor. Meanwhile Coke had further endangered his position by throwing out dark hints from the bench in his conduct of the Overbury trials ("God knows what became of that sweet babe, prince Henry, but I know somewhat"). Finally he came into collision with James once more over the king's right to allow *commendams* (holding of livings in plurality). The other judges submitted, but Coke merely said that he would do what an honest and just judge ought to do.

In June 1616 the privy council, with Bacon at the back of it, formulated three charges against him. One was a trumped-up matter, never proved, about a bond that had passed through his hands when he was attorney-general. The other two were charges of interference with the court of chancery, and of disrespect to the king in the matter of *commendams*. He was also ordered to revise the "errors" in his reports. Bacon, then attorney general, made himself very unpopular by engaging Coke on this last issue. Coke remained impenitent, and was dismissed. Thereupon, presumably in search of a friend in high places, he offered his daughter in marriage to Sir John Villiers, brother of the duke of Buckingham. His wife, supported by Bacon, objected, and hid

the child, who was then only fourteen. Coke found her and married her, strongly against her will, to Villiers. She ran away from him soon afterwards. However, Coke got back into the privy council by 1617, and sat in the Star Chamber. In 1620 he entered parliament as member for Liskeard, in theory as a supporter of the King. But for the rest of his career he was a leading member of the popular party. He strongly opposed the Spanish marriage proposals, took a part in drawing up the charges against Bacon, and spoke in the Liberties of Parliament debate, spending nine months in prison as a result. But nothing was found that could incriminate him. It was his Bill of Liberties that ultimately took the form of the Petition of Right. His last appearance was at the time when he saved the awkward situation caused by the speaker's suppressing Eliot's attack on the duke of Buckingham, who was, however, not mentioned by name. The House was at a loss, and in turmoil. Coke rose, and, having named the duke first, went on to say what the House thought of him; whereupon "as when one good hound recovers the scent the rest come in with a full cry so they . . . laid the blame where they thought the fault was." At the end of the session he retired, and died at Stoke Poges on Sept. 3, 1634. His papers were instantly seized, and some, including his will, never recovered.

Barrister, judge, and reporter of the first rank, Coke is the greatest common lawyer of all time. He was inclined to be overbearing and impatient both at the bar and on the bench, he was undoubtedly rather narrow, and he was not always logical. But his knowledge of the law, in days when it was far more difficult to come by than it is now, was unequalled, and to him more than anyone we owe the reduction of the chaos of the old authorities to the comparatively orderly state of the law as he left it. As a judge he is noted for his wholehearted adherence to the Common Law. He upheld it against the Church, the Admiralty, the Star Chamber, and, most dangerous of all, the royal prerogative, with success. He tried to uphold it against the Chancery, but that was too strong for him. While he was issuing his *Reports* no others came out. They are not so much reports in the modern sense as compendia of the law bearing on a particular case, with comments on points raised or general remarks. The best estimate of his importance as a legal authority is that of C. J. Best—"The fact is that Lord Coke had no authority for what he states, but I am afraid we should get rid of a great deal of what is considered law in Westminster Hall if what Lord Coke says without authority is not law. He was one of the most eminent lawyers that ever presided as a judge in any court of Justice. . . ." Among his other publications are four volumes of *Institutes* (1628), of which volume i. is known as *Coke upon Littleton*.

As a man, he evokes admiration more readily than sympathy. More learned a lawyer than Bacon but without his philosophical genius, a just judge but a savage prosecutor, obstinate in his opposition to illegal exercise of authority, but quite incapable of distinguishing between the prerogative, which wanted to override the law in the interests of absolutism, and the chancery, which sought to counteract its rigidity in the cause of justice, he was capable of cringing before the king even in the act of defying the Crown.

See C. W. Johnson, *Life of Sir Edward Coke* (2 vols., 1837); H. W. Woolrych, *The Life of Sir Edward Coke* (1826); Lord Birkenhead, *Fourteen English Judges* (1926); H. Lyon and H. Block, *Edward Coke, Oracle of the Law* (1929). See *Law Reports* of the period.

COKE, SIR JOHN (1563–1644), English politician, was born on March 5, 1563, and was educated at Trinity college, Cambridge. After leaving the university he entered public life as a servant of William Cecil, Lord Burghley, afterwards becoming deputy treasurer and then a commissioner of the navy. He became M.P. for Warwick in 1621 and was knighted in 1624, afterwards representing the University of Cambridge. In the parliament of 1625 Coke acted as secretary of State; in this and later parliaments he introduced the royal requests for money, and defended the foreign policy of Charles I. and Buckingham, and afterwards the actions of the king. His actual appointment as secretary dates from Sept. 1625. Disliked by the leaders of the popular party, his speeches in the House of Commons did not

improve the king's position, but when Charles ruled without a parliament he found Coke's industry very useful to him. The secretary retained his post until 1639, when a scapegoat was required to expiate the humiliating treaty of Berwick with the Scots, and Coke was dismissed. He died at Tottenham on Sept. 8, 1644. Coke's son, Sir John Coke, sided with the parliament in its struggle with the king, and it is possible that in later life Coke's own sympathies were with this party, although in his earlier years he had been a defender of absolute monarchy.

COKE, THOMAS (1747-1814), English divine, the first Methodist bishop, was born at Brecon, where his father was a well-to-do apothecary. He was educated at Jesus college, Oxford, taking the degree of M.A. in 1770 and that of D.C.L. in 1775. From 1772 to 1776 he was curate at South Petherton in Somerset, whence his rector dismissed him for adopting the open-air and cottage services introduced by John Wesley, with whom he had become acquainted. After serving on the London Wesleyan circuit he was in 1782 appointed president of the conference in Ireland, a position which he frequently held, in the intervals of his many voyages to America. He first visited that country in 1784, going to Baltimore as "superintendent" of the Methodist societies in the new world and, in 1787 the American conference changed his title to "bishop," a nomenclature which he tried in vain to introduce into the English conference, of which he was president in 1797 and 1805. Failing this, he asked Lord Liverpool to make him a bishop in India, and he was voyaging to Ceylon when he died on May 3, 1814. Coke had always been a missionary enthusiast, and was the pioneer of such enterprise in his connexion. He was an ardent opponent of slavery, and endeavoured also to heal the breach between the Methodist and Anglican communions. He published a *History of the West Indies* (1808-11), several volumes of sermons, and, with Henry Moore, a *Life of Wesley* (1792).

COKE, COKING AND HIGH TEMPERATURE CARBONIZATION. The product obtained by strongly heating coal out of contact with the air until the volatile constituents are driven off is called coke. It consists essentially of carbon, the so-called "fixed carbon," together with the incombustible matters or ash contained in the coal from which it is derived. In addition to these it contains, almost invariably, small quantities of hydrogen, oxygen and nitrogen, the whole, however, not exceeding 2 or 3%. It also contains water, the amount of which may vary considerably according to the method of manufacture. When produced rapidly and at a comparatively low heat, as in gas-making, it is of a dull black colour, and a loose spongy or pumice-like texture, and ignites with comparative ease, though much less readily than bituminous coal, so that it may be burnt in open fire-places; but when a long continued heat is used, as in the preparation of coke for iron and steel melting, the product is hard and dense, is often prismatic in structure, has—in the best class of coke—a brilliant semi-metallic lustre and silvery-grey colour, is a conductor of heat and electricity, and can only be burnt in furnaces provided with a strong draught. The strength and cohesive properties are also intimately related to the nature and composition of the coals employed, which are said to be "caking" or "non-caking" according to the compact or fragmentary character of the coke produced.

The first record of the coking of coal is in the 16th century, for in 1590 (*Cal. State Papers Dom.* 1581-90, p. 692) a patent was granted to John Thornborough, dean of York, the object of which was "to purify pit coal and free it from its offensive smell" by coking it. In Derbyshire, coke is mentioned by one Houghton, who wrote in 1693 (*Collection*, Ed. 1727, vol. i. p. 109). It had been used for 50 years in the drying of malt. The coal was "cowkified" by being piled up in large pyramidal form and charred.

There is an interesting mention of coking coal in Evelyn's diary under date July 11, 1656, "Came home," he writes, "by Greenwich Ferry, where I saw Sir John Winter's new project of *charring sea coale*, to burne without the sulphure and render it sweete. He did it by burning the coales in such earthen pots as the glasse-men melt their mettall, so firing them without consum-

ing them, using a barr of yron in each crucible or pot, which barr has a hook at one end, that so the coales being mealtd in a furnace with other crude sea coales under them, may be drawn out of the pots sticking to the yron, whence they are beaten off in great halfe-exhausted cinders, which being rekindl'd make a cleare pleasant chamber fire depriv'd of their sulphure and arsenic malignity. What success it may have time will discover."

William Bray, who edited Evelyn's diary in 1818, adds a footnote: "Some years ago Lord Dundonald revived the project, but with the projected improvement of extracting and saving the tar. Unfortunately his Lordship did not profit by it. The Gas Light Company sell the coal thus charred by the name of *coke*, for fuel for many purposes." So the inventive genius of Lord Dundonald sought to devise thus early a by-product recovery oven.

The quantity of coke imported into London—it was known as "Cinders" in the early days of its use—was in 1800, 7,939 chaldron or 10,122 tons, chiefly from the Tyne.

Coke Ovens.—Formerly coke was made from large coal piled in heaps with central chimneys like those of the charcoal burner, or in open rectangular clamps or kilns with air flues in the enclosing walls; but these methods are now obsolete, closed chambers or ovens being used. These vary considerably in construction, but may be classified into three principal types:—(1) direct-heated ovens; (2) flue-heated ovens, (3) condensing ovens. In the first class the heating is done by direct contact or by burning the gases off in coking within the oven, while in the other two the heating is indirect, the gas being burned in cellular passages or flues provided in the walls dividing the coking chambers, and the heat transmitted through the sides of the latter which are comparatively thin. The arrangement is somewhat similar to that of a gas-works retort, whence the name of "retort ovens" is sometimes applied to them. The difference between the second and third classes is founded on the treatment of the gases. In the former the gas is fired in the side flues immediately upon issuing from the oven, while in the latter the gases are first subjected to a systematic treatment in condensers, similar to those used in gas-works, to remove tar, ammonia and condensable hydrocarbons, the incondensable gases, or some portion of them, being returned to the oven and burned in the heating flues. These are generally known as "by-product recovery ovens."

Beehive Oven.—The simplest form of coke oven, but one now rapidly passing out of use, is the so-called "beehive oven." This is circular in plan, from 7 to 12 ft. in diameter, with a cylindrical wall about 2½ ft. high and a nearly hemispherical roof with a circular hole at the top. The floor, made of refractory bricks or slabs, is laid with a slight slope towards an arched opening in the ring wall, which is stopped with brickwork during the coking, but opened for drawing the finished charge. The ovens are usually arranged in rows or banks of 20 to 30 or more, with their doors outwards, two rows being often placed with a longitudinal flue between them connected by uptakes with the individual ovens on either side. A rail track along the top of the bank brings the coal from the screens or washery. The largest ovens take a charge of about five tons, which is introduced through the hole in the roof, the brick-work of the empty oven being still red hot from the preceding charge, and when levelled fills the cylindrical part nearly to the springing of the roof. The gas fires as it is given off and fills the dome with flame, and the burning is regulated by air admitted through holes in the upper part of the door stopping. The temperature being very high, a proportion of the volatile hydrocarbons is decomposed, and a film of graphitic carbon is deposited on the coke, giving it a semi-metallic lustre and silvery-grey colour. When the gas is burned off, the upper part of the door is opened and the glowing charge cooled by jets of water thrown directly upon it from a hose, and it is subsequently drawn out through the open door. The charge breaks up into prisms or columns whose length corresponds to the depth of the charge, and as a rule is uniform in character and free from dull black patches or "black ends." The time of burning is either 48 or 72 hours, the turns being so arranged as to avoid the necessity of drawing the ovens on Sunday. The longer the heat is continued the denser

the product becomes, but the yield also diminishes, as a portion of the finished coke necessarily burns to waste when the gas is exhausted. For this reason the yield on the coal charged is usually less than that obtained in retort ovens. Coals containing, at most, about 35% of volatile matter are best suited for the beehive oven. With less than 25% the gas is not sufficient to affect the coking completely, and when there is a higher percentage the coke is brittle and spongy and unsuited for blast furnaces or foundry use. The spent flame from the ovens is usually passed to a range of steam boilers before escaping by the chimney.

Retort Ovens.—The retort oven, which has so largely displaced the beehive form, is made in a great variety of forms, the differences being mainly in the arrangement of the heating flues, but all have the central feature, the coking chamber, in common. This is a tubular chamber with vertical or tapering sides and generally a cylindrical roof, about 30ft. long from 17 to 20in. wide, and 6 or 7ft. high, and closed at both ends by sliding doors which are raised by crab winches when the charge is to be drawn.

The general arrangement of a modern type of regenerative coke oven is shown in figs. 1 and 2. These show longitudinal and cross sections through the oven, which is of the vertical flued type. Fig. 1 shows a section through the oven chamber and the heating flues. The oven is a long rectangular chamber, the dimensions of which vary according to the class of coal to be carbonized and as to whether the coal is required to be carbonized in a compressed or uncompressed condition. For carbonizing dry uncompressed coal of normal character, the dimensions of the oven chamber would be 41ft. long by 13ft. high by 14in. wide at the bottom, tapering suitably to the top. Such an oven would take a charge of 12.5 tons and would have a carbonizing period of from 10 to 12 hours. The capacity would be, therefore, up to 20 tons per oven per day. For carbonizing wet compressed charges of coal, the ovens are designed to burn off in 16 to 18

BY COURTESY OF KOPPERS' COKE OVEN COMPANY

FIG. 1.—DIAGRAMMATICAL SKETCH OF A MODERN REGENERATIVE COKE OVEN

The coal is placed in the oven chambers and gradually carbonized. The gases are drawn to a by-product extraction plant, and after removal of tar, ammonia and benzol, are returned to the ovens. At the base of the flues, the gas mingles with heated air and combustion takes place. In this way the heat of the ovens is maintained. A valve system controls the regenerators, which are alternately heated by waste gases passing through them to outlet flues

hours, and have a carbonizing capacity of up to 10 tons of coke per oven per day.

The ovens are heated by the gas evolved from the coal during carbonization after it has passed through the condensing and scrubbing process incidental to the recovery of the by-products. The gas and air for combustion are separately distributed on each side and along the whole length of the oven, and combustion takes place in each flue. Separate regenerator chambers are provided for each oven so that each oven is independent of its neighbour (see fig. 2). This construction permits of the air for combustion and the chimney draught being separately regulated. In the older

type of regenerative ovens which were arranged with one set of regenerator chambers for a whole battery of ovens, there is a regulating damper over the passage leading from the regenerator chambers to the air distributing channel, which damper has to be set to serve the dual purpose of regulating the admission of air when the ovens are burning in one direction, and of regulating the chimney draught when the ovens are burning in the reverse direction.

The air for combustion passes into the regenerators through the inlet valves (fig. 1). In the regenerator the temperature of the air is raised to 1000° C., the highly-heated air passing out of the regenerators into the vertical heating flues through the openings (figs. 1 and 2). When normal coal is carbonized only from 35 to 40% of the gas evolved is required for heating the ovens. This is returned from the by-product recovery plant to the ovens by mains (fig. 1) running along the whole length of the battery of ovens on each side. Branch supply pipes (fig. 1) conduct the gas into the gas distributing channels (fig. 1 and 2) which are situated directly beneath the oven walls; thence it passes through the gas nozzles into each vertical flue where it ignites with the hot air entering through the passages (conduits). A jet is formed on the level of the oven floor along the whole length of the oven chamber. The supply pipes are each fitted with a regulating cock as well as a second cock fitted with a lever. All the levers are attached to a wire rope communicating with changing gear. The air is admitted to each regenerator by means of a cast-iron air valve which also serves to conduct the waste gases to the chimney flue. These valves are each fitted at the top with a lid connected, like the levers of the gas cocks, with a second wire rope, and the whole arrangement is such that when the changing gear operates, the gas cocks and valve lids on one side of the battery are closed simultaneously with the opening of the corresponding parts on the other side of the battery. When the gas is burning on one side of the ovens, the air valve is open and the air passes into the regenerator. A little below the valve lid there is a sliding shutter which can be set in any desired position and serves to regulate the quantity of air required for each oven.

When the gas is burning on the opposite side of the oven, the gas cocks and air valve lids are closed. The waste gases are, therefore, drawn through the cast-iron valve fitting into the chimney flue. At the base end of the cast-iron fittings there is a regulating damper which can be set in any desired position to regulate the draught on each oven. It will be seen, therefore, that by this arrangement, the quantity of air for each oven, and the chimney draught on each oven, can be separately regulated, which is not possible with ovens working with the older form of regenerators.

The employment of regenerators renders it necessary to reverse the heating process after a period of time, usually from 20 to 30 minutes, and the heating flues are divided into two sections so that combustion can take place alternately in each half of the oven wall. When the gas is burning in one half of the wall, the products of combustion pass up the flues and enter the top horizontal flue whence they make their way down the flues in the other half of the oven wall and enter the regenerator through the same passage by which the air is admitted to the flues when the direction of combustion is reversed. On issuing from the regenerators the waste gases pass into the flue leading to the chimney, after having given up their heat to the firebrick chequerwork. When the next half-hourly reversal is made, the heat is given up to the air entering for combustion.

The reversal of the heating process is effected by a simple winch arrangement placed at one end of the battery of ovens. The winch is operated automatically or by hand, and requires the least possible attention. When arranged to work automatically, the gear is so designed that should anything fail to act, an electric alarm is set in action and does not stop until the gear is again at work.

Two of the principal features of this type of oven are the sliding bricks and the openings in the top of the ovens which give access to them. The openings serve not only to provide means for regulating the dampers, but more particularly to give access to the gas nozzles.

In retort ovens when the gas is completely given off the doors are lifted and the charge is pushed out by the ram—a cast-iron plate of the shape of the cross section of the oven, at the end of a long horizontal bar, which is driven by a rack and pinion movement—on to the wharf or bank in front where it falls to pieces and is immediately quenched by jets of water from a hose pipe. When sufficiently cool it is loaded into railway wagons or other convey-

BY COURTESY OF KOPPERS COKE OVEN CO., LTD.

FIG. 2.—A CROSS-SECTION VIEW THROUGH SEVERAL KOPPERS' OVENS for removal. The ram, together with its motor, and boiler, when steam is used, is mounted upon a carriage running upon a line of rails of about 2 ft. gauge along the back of the range of ovens, so that it can be brought up to any one of them in succession.

In some cases instead of the small coal being charged through the roof of the oven and levelled by hand, it is forced into blocks by being stamped in a slightly moistened condition in a mould consisting of a bottom plate or peel on a racked rod like that of the ram, with movable sides and ends. This, when the ends are removed, is pushed forward into the oven, and the bottom plate is withdrawn by reversing the rack motion. The moulding box is mounted on a carriage like that of the ram, the two being sometimes carried on the same framing. The moulding is done at a fixed station in the centre of the range of ovens by a series of cast-iron stampers driven by an electric motor. This system is used for coals low in volatile matter, which do not give a coherent coke under ordinary conditions.

By-product Ovens.—In the distilling or by-product ovens the gases, instead of being burned at the point of origin, pass by an uptake pipe in the roof about the centre of the oven into a water-sealed collecting trough or hydraulic main, whence they are drawn by exhausters through a series of air and water cooled condensers and scrubbers. In the first or atmospheric condensers the tar is removed, and in the second ammoniacal water, which is further enriched by a graduated system of scrubbing with weak ammoniacal liquor until it is sufficiently concentrated to be sent to the ammonia stills. The first treatment by scrubbing with creosote or heavy tar oil removes benzene, after which the permanent gaseous residue consisting chiefly of hydrogen and marsh gas is returned to the ovens as fuel.

The number and kinds of coke ovens in use in Great Britain in the year 1926 were as follows:—

| | | | |
|-------------------------------|-------|-------------------------|-------|
| Koppers | 1,747 | Collins | 171 |
| Otto-Hilgenstock | 1,726 | Huessener | 262 |
| Simon Carvès | 1,650 | Carl Still | 72 |
| Semet-Solvay | 1,173 | Wilputte | 74 |
| Simplex | 471 | Makey Seymour | 32 |
| Coppée | 444 | Other kinds | 60 |
| Other kinds of ovens:— | | | |
| Coppée | 176 | Beehive Ovens | 2,229 |
| Tredegear | 120 | | |

The slow progress that was made in the direction of the replacement of "Beehive" by "Recovery oven" coke was apparently due to a rooted prejudice against its use in blast furnaces, but that has

now vanished, and fully three-quarters of the coal carbonized in Great Britain for metallurgical purposes is made in by-product recovery ovens.

Coke from retort ovens is not so dense or brilliant as that made in beehive ovens, but the waste being less there is a decided saving, apart from the value of the condensed products.

In the further treatment of the condensed products by distillation the tar gives burning oil and pitch, the benzene is separated from the creosote oil by steam-heated stills, and the ammoniacal liquor, after some lime has been added to decompose fixed ammonium compounds, is heated to vaporize the ammonia, which is condensed in lead or copper-lined tanks containing strong sulphuric acid to produce a crystalline powder of ammonium sulphate, which accumulates in the receiver and is fished out from time to time. The yield of coke and by-products obtained by the latest high temperature carbonization methods as applied in Great Britain is given below. (See Report of the Coal Carbonization Sub-Committee of the Coal Conservation Committee of 1919.)

Percentage Yields Calculated upon the Weight of Dry Coal Carbonized.

| Locality of the coal. | Coke. | Anhyd. tar. | Crude benzol. | Refined benzol. | Ammonium sulphate. |
|---------------------------|-------|-------------|---------------|-----------------|--------------------|
| Durham | 75 | 3.85 | 0.93 | 0.56 | 1.16 |
| South Yorkshire | 70 | 3.62 | 1.37 | 1.60 | 1.35 |
| Lancashire | 70 | 3.50 | 1.20 | 0.54 | 1.25 |
| South Wales | 80 | 2.62 | 0.60 | 0.35 | 0.95 |
| Scotland | 68 | 3.25 | 0.70 | ... | 1.00 |

After the ovens have been heated and steam supplied for the machinery of the condensing plant and the coke ovens, there is usually a surplus of gas, which may be used for lighting or driving gas-engines. For the latter purpose, however, it is necessary to remove the last traces of the tar, which acts very prejudicially in fouling the valves when the gas is not completely purified. The gas given off during the earlier part of the coking process is richer in heavy hydrocarbons and of a higher illuminating value than that of the later period when the temperature is higher. This property is utilized in several large coking plants in America, where the gas from the first 10 hours working is drawn off by a second hydraulic main and sent directly to town gas-works, where it passes through the ordinary purifying treatment, the gas from the second period being alone used for heating the ovens.

Nature of Coke.—Coke is essentially a partially graphitized carbon, its density being about midway between that of coal and graphite, and it should, therefore, occupy less space than the original coal; but owing to the softening of the charge a spongy structure is set up by the escaping gases, which acts in the other direction, so that for equal bulk coke is somewhat lighter than coal. It is this combination of properties that gives it its chief value in iron smelting, the substance being sufficiently dense to resist oxidation by carbon dioxide in the higher regions of the furnace, while the vesicular structure gives an extended surface for the action of heated air and facilitates rapid consumption at the tuyeres. Compact coke, such as that formed on the inner sides of gas retorts (retort carbon) can only be burned with great difficulty in small furnaces of special construction, but it gives out a great amount of heat.

The most deleterious constituents of coke are ash, sulphur and volatile constituents, including water. As the coke yield is only from two-thirds to three-quarters of that of the coal, the original proportion of ash is augmented by one-third or one-half in the product. For this reason it is now customary to crush and wash the coal carefully to remove intermingled patches of shale and dirt before coking, so that the ash may not, if possible, exceed 10% in the coke. According to the researches of F. Wuest (*Journ. Iron and Steel Inst.* 1906) the sulphur is retained in a complex carbon compound which is not destroyed until the coke is actually consumed.

The quantity of coal used in the manufacture of coke in Great Britain, taking the year 1925 as an example, is as follows:—

| | Tons. | Coke | Tons. |
|--|------------|----------|------------|
| In the manufacture of gas | 17,798,725 | produced | 11,832,842 |
| At coke ovens | 16,393,867 | do. | 11,008,686 |
| (See COAL; LOW TEMPERATURE CARBONIZATION.) (R. R.) | | | |

UNITED STATES

In the United States of America, the industry of coke-making has attained proportions greatly exceeding those in Great Britain, and has developed on somewhat different lines.

Beehive Coking.—As in Great Britain, so in America, beehive coking has been relegated to a minor rôle, and the principal share of the total coke production (in 1926, 78% and in 1927 about 86%) has of late years been in by-product recovery ovens. It is probable, however, owing to the very much lower cost of the beehive ovens, that they will for a long time continue to be used in such number as to supply an important proportion of the peak-load, surplus demand in a variable coke market. The lesser capital investment involved reduces very much the risk of loss from idle equipment. The rectangular or longitudinal form of non-recovery oven (as well as the "beehive" form) is used in the United States. This may take a charge of 8 to 10 tons, and usually employs a ram to discharge the coke. Waste heat is recovered at some of the large beehive coking plants and utilized in firing boilers. The amount of power recoverable in this way has been found by actual measurement to be 15 to 20 h.p. per hour from each oven. Roughly this amounts to 50 to 60% of the fuel energy recovered ordinarily in the by-products from by-product coke oven operations.

Disposal of Coke and Gas.—In England only about half of the total coke produced is used in making iron and steel, but in America, 75 to 80%. In other words, America devotes a much smaller proportion of her coke output to domestic and miscellaneous industrial uses, than does England, although in actual tonnage so disposed annually the two countries do not differ greatly. In the disposal of gas also from by-product coke ovens, the American practice is quite different from the British. Coke ovens in America are an important factor in the manufactured gas industry as a public utility. In 1925, they produced 77,500,000 cu.ft. or more than 20% of all manufactured gas publicly distributed in city mains, besides about 260,000,000 cu.ft. that was sold direct to industrial users and not included in distribution by public systems. In England practically none of the gas for public distribution is derived from coke ovens.

By-product Coke Ovens.—In America practically no distinction is made between the "retort oven" and the "by-product oven," the latter being the more common term. About 90% of all the by-product coke is made in ovens heated by vertical flues, employing the regenerative principle of utilizing waste heat, as distinguished from the horizontal-flued type and recuperative heat recovery.

Refractory brick of "silica" material are used in the oven wall construction, having almost entirely superseded clay brick for this purpose. This refractory, owing to its rigidity under load when highly heated, permits the use of higher temperatures in the flues and thus secures more rapid working and greater oven capacity than is attainable with fire-clay brick. Flue temperatures of 1,370° to 1,400° C (2,500° to 2,550° F) are sometimes used in modern American ovens, but their average practice would be at somewhat lower heats.

The modern by-product coke oven in America is a rectangular chamber of about 500–550 cu.ft. coal-charging capacity. It has a length of about 40ft., a height of 12 to 13ft. and an average width (tapering 2 or 3in. throughout the length) of about 14 to 17 inches. With this oven, using finely crushed but not "stamped" coal, a charge of 12 to 16 tons (2,000lb. each) is obtained, and a daily coking capacity of 20 to 25 tons of coal. The ovens are built closely adjoining one another in batteries or banks, usually about 40 to 60 in a battery, for convenience in operating. The rows of heating flues stand between the ovens, each row serving to heat two ovens, except in

set of flues on either side.

A favourite type of by-product oven in the United States is the Becker modification of the Koppers oven. The general arrangement of a typical installation of ovens and heating flues would have a battery provided with both producer-gas heating (from a lower and larger supply pipe), and coal-gas heating (*i.e.*, by surplus coke oven gas), from the upper and smaller supply pipe. These ovens are heated on the regenerative principle, the waste heat of the combustion gases being retained in checker brick chambers below the ovens and at intervals, on reversal of current, given up to the entering air or producer gas. The distinguishing feature of the Becker oven is its provision for conducting the gases of combustion from the top of a row of flues across over the oven and down the row of flues on the other side. The cross-over flues, of an inverted U shape, are in the upper part of the oven battery structure. They pass over alternate ovens only, and are generally six in number, evenly distributed throughout the length of the oven. In the six cross-over flue arrangement the waste gases are taken from a common horizontal duct into which they pass from 28 vertical flues in the row underneath. The horizontal duct is in two sections, each communicating with 14 vertical flues and carrying the gases into three cross-over flues. Special insulating bricks are placed around the cross-over flues to protect the oven tops from excessive heat.

The advantages of this type of oven are concerned chiefly with securing more uniform heating of the ovens and a more stable structure in the upper part of the flue wall. The burning of gases, when reversed in direction, at intervals, for the purpose of regeneration, is not reversed from one-half of a heating wall to the other as in the older types, but from an entire wall on one side to an entire wall on the other side of an oven. This makes for more uniform heating, end to end, of the oven walls. The old horizontal flue of large size (above the row of vertical flues) is, in the new type, very much reduced in size owing to the provision of the cross-over flues, which reduce the volume of gases to be carried in any one section of the horizontal duct. This allows heavier wall structure in this region and permits the heating flues to be built up higher without risk of overheating the oven tops, and the charge to be more evenly coked.

In Sept. 1926 there were, in the United States, completed and in operation, the following numbers of by-product ovens of the various types:—

| | |
|--|--------|
| Koppers (including Koppers-Becker) | 7,724 |
| Semet-Solvay | 2,174 |
| United Otto | 972 |
| Cambria-Belgian | 310 |
| Wilputte | 303 |
| Roberts | 104 |
| American (Foundation Co.) | 55 |
| Klönne | 42 |
| Morrissey | 25 |
| Piette | 8 |
| Total | 11,717 |

Coke is designated by the length of time that it is cooked or burned; by the ash and sulphur content and by size. The following sizes are commonly used: Egg, Large Stove, Small Stove, Chestnut, $\frac{3}{4}$ " Pea, $\frac{1}{2}$ " Pea, Dust Coke, Coke Dust or Coke Breeze. The first four grades are used for house heating, small forgings, etc., the Pea size for chemical works, etc., and Dust for covering the bottoms of soaking pits and crucible furnaces to protect the brickwork from melted scale.

The Vertical Oven.—On account of certain economies in operation and in ground space requirements, and especial adaptability to the needs of small installations for town's gas supply, the small vertical chamber oven, intermittently operated, is coming into use in the United States for the manufacture of coal gas. One type of this oven, installed in America, is heated by producer gas made in a specially arranged "built-in" producer, the air being pre-heated by recuperation. This type of oven is of rectangular shape about 12in. wide by 10ft. long and 22ft. high, in the larger size, or 6 $\frac{1}{2}$ ft. long and 18ft. high in the smaller size. It is built in benches of two to six ovens each, with six benches, or more, in a battery. It is adapted for steaming of the charge at the bottom.

This type of carbonizing equipment has the advantage of discharging its coke by gravity, doing away with the cumbersome pushing machines of the horizontal coke ovens; also a greater facility for utilization of the sensible heat of the coke discharge.

Carbonization Practice.—In America there are some points of difference in high temperature carbonization practice, as compared with that in Britain. When two kinds of coal are mixed, for by-product coking, as is frequently done, the coal is very generally "pulverized," *i.e.*, finely crushed, until at least 75% passes a $\frac{1}{16}$ in. screen. Even when using a single coal this is sometimes done, but now the crushing in that case is more often to about $\frac{1}{16}$ in. size. For many of the American "high-volatile" coals (31 to 38% volatile matter) it is found advantageous to add 15 to 30% of a lower volatile coal (so called "semi-bituminous" coal of 17 to 22% volatile matter) in order to obtain best metallurgical cokes.

Stamping, or compressing of the coal charge, is not practised in America.

The quenching of coke is now done very generally at a quenching station, a short distance away from the oven battery. The car containing the hot coke is quickly moved from the oven to the station, is there quenched with a carefully controlled amount of water, and then brought back to an inclined wharf along the oven battery where it is dumped and undergoes further cooling and drying. "Dry quenching," using inert gases (products of combustion) or steam, is being tried in several American plants, with a marked degree of success.

In the recovery of by-products, the so-called "direct process" of ammonia recovery has been adopted in the majority of American plants. This consists in passing the oven gases, after removal of their tar, directly through sulphuric acid, in lead-lined "saturators," whereby the ammonia is converted into solid crystalline ammonium sulphate.

The practice known as "gas separation" whereby the richer gases from the earlier part of the coking period are separately collected, was at one time carried on at a number of American plants, but is going out of use, owing to the general abandonment of lighting quality standards for gas.

The following yields of products in by-product coking, according to American practice, are an approximate average, as close as can be estimated under conditions varying so widely:—

Percentage Yields from a Mixture of 80% Pittsburgh and 20% Pocahontas Coal

(Dry Basis)

| | |
|---|-------|
| Coke (total) | 72.0% |
| Tar | 5.0% |
| Benzols, crude | 1.0% |
| Ammonium sulphate | 1.2% |
| Gas "surplus," per pound coal, B.t.u. content | 2,100 |

The production of coke in the United States, in 1926, in coke ovens (not including gas works coke from retorts) was as follows:—

| | Short Tons | Per cent. |
|-----------------------|------------|-----------|
| From by-product ovens | 44,376,586 | 78.0 |
| From beehive ovens | 12,488,951 | 22.0 |
| Total | 56,865,537 | 100.0 |

Approximately 2,500,000 tons additional were produced in gas retorts. (H. C. Pr.)

"COKE OF NORFOLK": see LEICESTER OF HOLKHAM, THOMAS WILLIAM COKE, EARL OF.

COL, in physical geography, generally any distinct depression upon a high water-parting offering easy passage from one valley to another. There are numerous cols on the Franco-Italian frontier, *e.g.*, the Little St. Bernard (2,188ft.) which carries the road from the Dora Baltea to the upper Isère. The col (Fr. for "neck," *Lat. collum*) is usually formed by the headwaters of streams eating backwards towards one another and lowering the water-parting between their valley-heads. In early military operations, the most convenient col controlled the route of the army's movement.

COLBERT, JEAN BAPTISTE (1619–1683), French statesman, was born at Reims, where his father and grandfather were merchants. Through a family connection with Michel le

Tellier, secretary of State for war, Colbert obtained a place in the war office before he was 20 and presently became private secretary to the minister. Twelve years later he became agent to Mazarin, driven from Paris (1651) during the supremacy of the Condé family, with the duty of keeping him informed of the progress of events. On his return, Mazarin gratified his agent with honours and places for various members of his family, and gave him his entire confidence. After Mazarin's death, Colbert secured the favour of Louis XIV. and became the chief power in the administration, though he did not at first hold an official position.

The king's new adviser set to work at once to reform the chaotic financial administration of France. He began by striking at the *surintendant*, Nicolas Fouquet, and secured his disgrace. The office of *surintendant* was abolished, and the control of finance was vested for a time in a royal council. Colbert, who contented himself with the title of *intendant*, was the ruling spirit of this council, but did not take over nominal direct control until 1665, when he was made controller-general. His first measures for cleansing the financial administration were ruthless enough. He set up a tribunal to deal with officials who intercepted money due to the treasury. Many were condemned to death, though the death sentences were not carried out; some 4,000 were compelled to disgorge their gains. The tribunal was disbanded in 1665, but it had purified the service. The public debt was handled by drastic methods. Some series of bonds were repudiated on the ground that only a small part of the money had been paid in; others were cancelled by paying the original sum invested less the interest paid. Colbert did not propose the abolition of privilege, but he drew into the net of taxation many who had hitherto escaped by revising the application of the *taille*, or direct tax. Indirect taxes were increased and the tariff revised in 1664, as part of a protective system. The various dues which existed among the provinces could not be swept away, but, although internal fiscal barriers were not destroyed, a measure of uniformity was secured in central France. His reforms in the farming out and collection of taxes and the jealous watch kept on the officials brought large sums into the treasury.

Colbert then turned his attention to the general increase of wealth by the encouragement of industry. He had a narrow conception of prosperity, which in his mind could not be real if neighbouring countries were prosperous. And in his encouragement of industry and trade he used the same minute method of centralized regulation which had brought order into the fiscal system. Every detail was to be controlled. This minute regulation probably accounts for the failure of the great trading corporations which he set up in 1664 for trading in India and in America (the East Indies and West Indies companies), while the British and Dutch monopolistic trading companies, with their operations untrammelled by the home government, prospered. He set up model factories, either financed by State funds as in the case of the Gobelins (founded 1667) or by concessionaries. He sought to standardize the production of staple commodities for all producers; faulty workmanship or deviation from the standard was punished by fine and by exposure in the pillory. These regulations hampered industry and annoyed the producers, and the encouragement given to industry tended to starve agriculture. French industry was to be developed by administrative measures and by a high protective tariff, and the proceeds accruing to the State were to be used for the development of communications and of external trade. The roads and canals were improved. The great canal of Languedoc was planned and constructed by Pierre Paul Riquet (1604–80) under Colbert's patronage.

The greatest and most lasting of Colbert's achievements was the establishment of the French marine. He became minister of the marine in 1669; then, in addition, of the colonies and the king's palace. The royal navy owed all to him, for the king thought only of military exploits. Colbert reconstructed the works and arsenal of Toulon, founded the port and arsenal of Rochefort, and the naval schools of Rochefort, Dieppe, and St. Malo, and fortified, with some assistance from Vauban (who, however, belonged to the party of his rival Louvois), among other ports those

of Calais, Dunkirk, Brest, and Havre. To supply it with recruits he invented his system of classes, by which each seaman, according to the class in which he was placed, gave six months' service every three or four or five years. For three months after his term of service he was to receive half-pay; pensions were promised; and, in short, everything was done to make the navy popular. There was one department, however, that was supplied with men on a very different principle. The galleys used in the Mediterranean service required oarsmen. Colbert wrote to the judges requiring them to sentence to the oar as many criminals as possible; and the convict, once chained to the bench, the expiration of his sentence was seldom allowed to bring him release. Vagrants, contraband dealers, political rebels, Turkish, Russian, and negro slaves, and poor Iroquois Indians, whom the Canadians were ordered to entrap, were pressed into that terrible service. By these means the benches of the galleys were filled, and Colbert took no thought of the long agony of those who filled them.

Encouragement was given to the building of ships for the mercantile marine by allowing a premium on those built at home, and imposing a duty on those brought from abroad; and as French workmen were forbidden to emigrate, so French seamen were forbidden to serve foreigners on pain of death.

Colbert was a patron of art and literature. He possessed a fine private library, rich in valuable manuscripts. He founded the academy of sciences, the observatory, which he employed Claude Perrault to build and brought G. D. Cassini (1625-1712) from Italy to superintend, the academies of inscriptions and medals, of architecture, and of music, the French academy at Rome, and academies at Arles, Soissons, Nîmes, and many other towns, and he reorganized the academy of painting and sculpture which Richelieu had established. He was a member of the French academy. In 1673 he presided over the first exhibition of the works of living painters; and he enriched the Louvre with hundreds of pictures and statues. He gave many pensions to men of letters, among whom we find Molière, Corneille, Racine, Boileau, P. D. Huet (1630-1721) and Antoine Varillas (1626-96), and even foreigners, as Huyghens, Vossius the geographer, Carlo Dati the Dellacruscan, and Heinsius the great Dutch scholar.

Colbert's industry was colossal. He found time to do something for the better administration of justice (the codification of ordinances, the diminishing of the number of judges, the reduction of the expense and length of trials for the establishment of a superior system of police) and even for the improvement of the breed of horses and the increase of cattle. As superintendent of public buildings he enriched Paris with boulevards, quays, and triumphal arches; he relaid the foundation stone of the Louvre, and brought Bernini from Rome to be its architect; and he erected its splendid colonnade upon the plan of Claude Perrault, by whom Bernini had been replaced. He was not permitted, however, to complete the work, being compelled to yield to the king's preference for residences outside Paris, and to devote himself to Marly and Versailles.

Amid all these public labours he directed personally the management of every farm on his estates. He died extremely rich and left fine estates all over France. He had been created marquis de Seignelay, and for his eldest son he obtained the reversion of the office of minister of marine; his second son became archbishop of Rouen; and a third son, the marquis d'Ormoy, became superintendent of buildings.

To carry out his reforms, Colbert needed peace and consistently advocated it, except in the case of the Dutch War, for which his commercial policy was partly responsible; but the war department was in the hands of his great rival Louvois, whose influence gradually supplanted that of Colbert with the king. Louis decided on a policy of conquest. He was deaf also to all the appeals against the other forms of his boundless extravagance which Colbert ventured to make (*Lettres*, vol. ii.). Thus, only a few years after he had begun to free the country from the weight of the loans and taxes which crushed her to the dust, Colbert was forced to heap upon her a new load of loans and taxes heavier than the last. Depressed by his failure, deeply wounded by the king's favour for Louvois, and worn out by overwork, his strength gave way at a

comparatively early age.

Colbert was a great statesman, who did much for France. Nevertheless, his rule was a very bad example of over-government. He did not believe in popular liberty; the parlements and the states-general received no support from him. The technicalities of justice he never allowed to interfere with his plans; and he did not hesitate to shield his friends. He trafficked in public offices for the profit of Mazarin and in his own behalf. He caused the suffering of thousands in the galleys. There was indeed a more human side to his character, shown to his own family, but to all outside he was "the man of marble." Madame de Sévigné called him "the North Star." To diplomacy he never pretended.

BIBLIOGRAPHY.—The most thorough student of Colbert's life and administration was Pierre Clément, member of the Institute, who in 1846 published his *Vie de Colbert*, and in 1861 the first of the 9 vols. of the *Lettres, instructions et mémoires de Colbert*. The historical introductions prefixed to each of these volumes have been published by Mme. Clément under the title of the *Histoire de Colbert et de son administration*, 3rd ed. (1892). The best short account of Colbert as a statesman is that in Lavisse, *Histoire de France* (1905), which gives a thorough study of the administration. See also Benôit du Rey, *Recherches sur la politique coloniale de Colbert* (1902). Among Colbert's papers are *Mémoires sur les affaires de finance de France* (written about 1663), a fragment entitled *Particularités secrètes de la vie du Roy*, and other accounts of the earlier part of the reign of Louis XIV.

COLBERT DE CROISSY, CHARLES, MARQUIS (1625-1696), French diplomatist, like his elder brother Jean Baptiste Colbert, began his career in the office of the minister of war, Le Tellier. In 1656 he bought a counsellorship at the parlement of Metz, and in 1658 was appointed intendant of Alsace and president of the newly-created sovereign council of Alsace. In this position he had to reorganize the territory recently annexed to France. The steady support of his brother at court gained for him several diplomatic missions—to Germany and Italy (1659-61). In 1662 he became marquis de Croissy and *président à mortier* of the parlement of Metz. After various intendantships, at Soissons (1665), at Amiens (1666) and at Paris (1667), he turned definitely to diplomacy. In 1668 he represented France at the conference of Aix-le-Chapelle; and in August of the same year was sent as ambassador to London, where he was to negotiate the definite treaty of alliance with Charles II. He arranged the interview at Dover between Charles and his sister Henrietta of Orleans, gained the king's personal favour by finding a mistress for him, Louise de Kérouaille, maid of honour to Madame, and persuaded him to declare war against Holland. The negotiation of the treaty of Nijmegen (1676-78) still further increased his reputation as a diplomatist, and Louis XIV. made him secretary of state for foreign affairs after the disgrace of Arnauld de Pomponne, brought about by his brother, 1679. He at once assumed the entire direction of French diplomacy. It was he, not Louvois, who formed the idea of annexation during a time of peace, by means of the chambers of reunion. He had outlined this plan as early as 1658 with regard to Alsace. His policy at first was to retain the territory annexed by the chambers of reunion without declaring war, and for this purpose he signed treaties of alliance with the elector of Brandenburg (1681), and with Denmark (1683); but the troubles following upon the revocation of the Edict of Nantes (1685) forced him to give up his scheme and to prepare for war with Germany (1688). The negotiations for peace had been begun again when he died, on July 28, 1696.

BIBLIOGRAPHY.—His papers, preserved in the *Archives des affaires étrangères* at Paris, have been partially published in the *Recueil des instructions données aux ambassadeurs et ministres de France* (since 1884). See especially the volumes:—*Autriche* (t.i.), *Suède* (t.ii.), *Rome* (t.vi.), *Bavière* (t.viii.), *Savoie* (t.xiv.), *Prusse* (t.xvi.). Other documents have been published in Mignet's *Négociations relatives à la succession d'Espagne*, vol. iv., and in the collection of *Lettres et négociations... pour la paix de Nimègue, 1676-77* (La Haye, 1710). In addition to the *Mémoires* of the time, see Spanheim, *Relation de la cour de France en 1690*, edit. E. Bourgeois (Lyons, 1900); Baschet, *Histoire du dépôt des affaires étrangères*; C. Rousset, *Histoire de Louvois* (1863); E. Bourgeois, "Louvois et Colbert de Croissy," in the *Revue Historique*, vol. xxxiv. (1887); A. Waddington, *Le Grand Électeur et Louis XIV.* (1905); G. Pagis, *Le Grand Électeur et Louis XIV.* (1905).

COLBURN, HENRY (d. 1855), British publisher. In 1814 he originated the *New Monthly Magazine*, of which at various times Thomas Campbell, Bulwer Lytton, Theodore Hook and Harrison Ainsworth were editors. Colburn published in 1818 *Evelyn's Diary*, and in 1825 the *Diary of Pepys*, edited by Lord Braybrooke, paying £2,200 for the copyright. He also issued Disraeli's first novel, *Vivian Grey*. His business was taken over in 1841 by Messrs. Hurst and Blackett. Henry Colburn died on Aug. 16 1855.

COLBY, FRANK MOORE (1865–1925), American editor, was born in Washington D.C., Feb. 10 1865. He received from Columbia university the degrees A.B. (1888) and A.M. (1889). He was acting professor of history at Amherst college (1890–91), lecturer and instructor in history and economics at Columbia university and Barnard college (1891–95) and professor of economics at New York university (1895–1900). In 1893 he joined the editorial staff of *Johnson's Universal Cyclopaedia*. In 1898 he became editor of *The International Year Book*, and he was one of the editors of *The International Cyclopaedia* and of the first and second editions of *The New International Encyclopaedia*. He served as American editor of *Nelson's Encyclopaedia* (1905–06), and after 1907 as editor of *The New International Year Book*. He died in New York City, March 3 1925. He wrote, among other works, *Imaginary Obligations* (1904); *Constrained Attitudes* (1910); and *The Margin of Hesitation* (1922).

COLCHAGUA, a province of central Chile, bounded N. by Santiago, E. by Argentina, S. by Talca, and W. by the Pacific. Its area, before annexations made in 1928, was 3,851 sq.m.; pop. (1920) 166,342. Pop. (1928), including that of the added territory, is about 300,000. Extending across the great central valley of Chile, the province has a considerable area devoted to agriculture, but much attention is given to cattle and mining. Its principal river is the Rapel, sometimes considered as the southern limit of the Inca empire. Its greatest tributary is the Cachapoal, in the valley of which, among the Andean foothills, are the popular thermal mineral baths of Cauquenes, 2,306ft. above sea-level. The State central railway from Santiago to Puerto Montt crosses the province and has two branches within its borders, one from Rengo to Peumo, and one from San Fernando via Palmilla to Pichilemu on the coast. The principal towns are the capital, Rancagua, San Fernando, Rengo and Palmilla. San Fernando is one of the several towns founded in 1742 by the governor-general José de Manso, pop. (1920) 10,753. Rengo is an active commercial town and had a population of 6,681 in 1920. The population of Rancagua was estimated in 1927 at 19,700.

COLCHESTER, CHARLES ABBOT, 1ST BARON (1757–1829), was born in Abingdon, and educated at Westminster school and Oxford. In 1795, after having practised 12 years as a barrister, he was appointed clerk of the rules in the king's bench and elected member of parliament. To his efforts were due the establishment of the Royal Record Commission, the reform of the system which had allowed the public money to lie for long periods in the hands of the public accountants, by charging them with payment of interest, and, most important of all, the act for taking the first census (1801). In March 1801 Abbot became chief secretary and privy seal for Ireland; and in 1802 he was chosen speaker of the House of Commons. In response to an address of the Commons, he became Baron Colchester, with a pension of £4,000. He died on May 8, 1829.

COLCHESTER, municipal borough, Essex, England; 52 m. north-east from London by L.N.E.R., on the river Colne, 12 m. from the open sea. Pop. (1931) 48,607.

The Roman town, *Colonia Victricensis Camalodunum* (or *Camulodunum*), was founded by Claudius, soon after the Roman conquest, as a municipality of discharged Roman soldiers. Under Boadicea natives burned the town and massacred the colonists; but Camalodunum soon rose again. Its walls, with remains of the guardroom at the principal gate, can still be clearly traced. Roman sculptures, inscriptions, pavements and pottery have also been discovered. Domesday mentions 276 burgesses and land *in commune burgensium*. The ruined castle-keep of the reign of William I. or William II. is quadrangular, turreted at the angles,

and is the largest of its kind in England. In the castle is a museum of Roman and other antiquities. The Augustinian priory of St. Botolph (early 12th cent.) retains part of the fine Norman west front (in which Roman bricks occur), and of the nave arcades; and there is the restored gateway of the Benedictine monastery of St. John, a beautiful specimen of Perpendicular work, embattled, flanked by spired turrets, and covered with panel work. The church of Holy Trinity has an apparently pre-Norman tower.

The first charter given in 1189 granted freedom of passage and pontage through England, free warren, fishery and custom as in the time of Henry I. The charters were confirmed and new grants obtained in 1447 and 1535. Colchester returned two members to parliament from 1295 until 1885. Fairs were granted by Richard I. in 1189 to the hospital of St. Mary Magdalene, and by Edward II. in 1319 on the eve of St. Denis and the six following days. In the 13th century Colchester was an important port, its ships plying to Winchelsea and France. Elizabeth and James I. encouraged Flemish settlers in manufacture of baize ("bays and says"). Both Camden and Fuller mention the trade in barrelled oysters and candied eringo-root. The town was held, apparently against the citizens' will, by Royalists in 1648 against Fairfax, and it was fined in consequence by the Parliament.

Charles I. granted a fresh charter, which was amended in 1653 and a new one granted in 1663; this one remaining in force with modifications until 1741. In 1763 George III. made the borough a renewed grant of its liberties. The town has long been an important military centre and is the headquarters of the Eastern military district. There is a free grammar school (founded 1539). Castle Park is a public ground surrounding the castle. Colchester is the centre of an agricultural district, and has extensive corn and cattle markets, with some small dependent industries. The oyster fisheries at the mouth of the Colne belong to the corporation, and are held on lease by the Colne Fishery Company. The harbour, with quayage at the suburb of Hythe, is controlled by the corporation. Since 1918 the municipal borough of Colchester together with the rural district of Lexden and Winstree (except the detached portion of Inworth Parish) form the Colchester Parliamentary Division of Essex. Area of municipal borough, 11,333 acres.

Colchester was made the see of a suffragan bishop by Henry VIII., and two bishops were in succession appointed by him; no further appointments, however, were made until the suffragan see was re-established under Victoria.

COLCHICUM, the meadow saffron, or autumn crocus (*Colchicum autumnale*), a perennial plant of the family Liliaceae, found wild in rich, moist meadow-land in England and Ireland, in middle and southern Europe and in the Swiss Alps. It has pale-purple flowers, rarely more than three in number; the perianth is funnel-shaped, and produced below into a long slender tube, in the upper part of which the six stamens are inserted. The ovary is three-celled, and lies at the bottom of this tube. The leaves are three or four in number, flat, lanceolate, erect and sheathing; and there is no stem. Propagation is by the formation of new corms from the parent corm, and by seeds. The latter are numerous, round, reddish-brown and of the size of black mustard-seeds. The corm of the meadow-saffron attains its full size in June or early in July. A smaller corm is then formed from the old one, close to its root; and this in September and October produces the crocus-like flowers. In the succeeding January or February it sends up its leaves, together with the ovary, which perfects its seeds during the summer. The young corm grows continuously, till in the following July it attains the size of a small apricot. The parent corm remains attached to the new one, and keeps its form and size till April in the third year of its existence, after which it decays. In some cases a single corm produces several new plants during its second spring by giving rise to immature corms. *C. autumnale* and its numerous varieties, as well as other species of the genus, are well known in cultivation, forming some of the most beautiful of autumn-flowering plants.

Colchicum or colchicine, applied to the skin, causes pain and congestion; inhaled, causes violent sneezing; and taken internally,

increases the amount of bile poured into the intestine. In larger doses it is a violent gastro-intestinal irritant, causing severe colic, vomiting, diarrhoea, haemorrhage from the bowel and ultimately death from collapse. This is accelerated by a depressant action upon the heart and nervous system similar to that produced by veratrine and aconite. The action of the drug upon the kidneys has been studied, but is not yet fully clear.

The sole medical use of colchicum is in gout. It has an extraordinary power over the pain of acute gout; lessens the severity and frequency of the attacks when given continuously between them, and benefits such symptoms of gout as eczema, bronchitis and neuritis, though inoperative against them when not of gouty origin. Veratrine, a constituent of the colchicum corm, is useless in the treatment of gout. The drug is generally given as *vinum colchici*, in doses of 10 to 30 minims. It is apt to render the patient low-spirited and tearful and must only be given with great care.

In *colchicum poisoning*, empty the stomach, give white of egg, olive or salad oil and water. Use hot bottles and stimulants, especially trying to counteract the cardiac depression by atropine, caffeine, strophanthin, etc.

COLCHIS, in ancient geography, a nearly triangular district of Asia Minor, at the eastern extremity of the Black Sea, bounded on the north by the Caucasus, which separated it from Asiatic Sarmatia, east by Iberia, south by the Montes Moschici, Armenia and part of Pontus, and west by the Euxine. The name of Colchis first appears in Aeschylus and Pindar. It was inhabited by a number of tribes whose settlements lay chiefly along the shore of the Black Sea. These tribes differed so completely in language and appearance from the surrounding nations, that the ancients originated various theories to account for the phenomenon. Herodotus believed them to have sprung from the relics of the army of Sesostris (*q.v.*), and thus regarded them as Egyptians. Apollonius Rhodius (*Argon*, iv. 279) states that the Egyptians of Colchis preserved as heirlooms a number of wooden *κύρβεις* (tablets) showing seas and highways with considerable accuracy. It is quite possible that there was an ancient trade connection between the Colchians and the Mediterranean peoples. We learn that women were buried, while the corpses of men were suspended on trees. The principal coast town was the Milesian colony of Dioscurias (Roman Sebastopolis; mod. Sukhum Kaleh), the ancient name being preserved in the modern C. Iskuriia. The chief river was the Phasis (mod. Rion).

Colchis was celebrated in Greek mythology as the destination of the Argonauts, the home of Medea and the special domain of sorcery. Several Greek colonies were founded there by Miletus. It seems to have been incorporated in the Persian empire, though the inhabitants evidently enjoyed a considerable degree of independence; in this condition it was found by Alexander the Great, when he invaded Persia. From this time till the era of the Mithridatic wars nothing is known of its history. At the time of the Roman invasion it seems to have paid a nominal homage to Mithridates the Great and to have been ruled over by Machares, his second son. On the defeat of Mithridates by Pompey, it became a Roman province. After the death of Pompey, Pharnaces, the son of Mithridates, rose in rebellion against the Roman yoke, subdued Colchis and Armenia, and made head, though but for a short time, against the Roman arms. After this Colchis was incorporated with Pontus, and the Colchians are not again alluded to in ancient history till the 6th century. It had been specially garrisoned by Justinian under first Peter, a Persian slave, and subsequently Johannes Tzibos, who built Petra on the coast as the Roman Headquarters. Tzibos took advantage of the extreme poverty of the inhabitants to create a Roman monopoly by which he became a middleman for all the trade both export and import. Chosroes I. succeeded in capturing Petra (A.D. 541). The missionary zeal of the Zoroastrian priests soon caused discontent among the Christian inhabitants of Colchis, and Gobazes, perceiving that Chosroes intended to Persianize the district, appealed to Rome, with the result that in 549 one Dagisthaeus was sent out with 7,000 Romans and 1,000 auxiliaries of the Tzani (Zani, Sanni). The "Lazic War" lasted till 556 with varying success.

Petra was recaptured in 551 and Archaeopolis was held by the Romans against the Persian general Mermeroes. Gobazes was assassinated in 552, but the Persian general Nachoragan was heavily defeated at Phasis in 553.

By the peace of 562 the district was left in Roman possession, but during the next 150 years it is improbable that the Romans exercised much authority over it. In 697 we hear of a revolt against Rome led by Sergius the Patrician, who allied himself with the Arabs. Justinian II. in his second period of rule sent Leo the Isaurian, afterwards emperor, to induce the Alans to attack the Abasgi. The Alans invaded Lazica, and, probably in 712, a Roman and Armenian army laid siege to Archaeopolis. On the approach of a Saracen force they retired, but a small plundering detachment was cut off. Ultimately Leo joined this band and aided by the Apsilian chief Marinus escaped with them to the coast.

From the beginning of the 14th to the end of the 17th century Colchis was governed by an independent dynasty, the Dadians, which was succeeded by a semi-independent dynasty, the Chikovans, who by 1838 had submitted to Russia, though they retained a nominal sovereignty. In 1866 the district was finally annexed by Russia. See GEORGIA.

For the kings see Stokvis, *Manuel d'histoire*, i. 83.

COLCOTHAR (adapted in Romanic languages from Arabic *golgotar*, which was probably a corruption of the Gr. *χαλκανθος* from *χαλκός*, copper, *άνθος*, flower, *i.e.*, copper sulphate), a name given to the brownish-red ferric oxide formed in the preparation of fuming sulphuric (Nordhausen) acid by distilling ferrous sulphate. It is used as a polishing powder, forming the rouge of jewellers, and as the pigment Indian red. It is also known as *Crocus Martii*.

COLD, subjectively the sensation which is excited by contact with a substance whose temperature is lower than the normal; objectively a quality or condition of material bodies which gives rise to that sensation. Whether cold, in the objective sense, was to be regarded as a positive quality or merely as absence of heat was long a debated question. Thus Robert Boyle, who does not commit himself definitely to either view, says, in his *New Experiments and Observations touching Cold*, that "the dispute which is the *primum frigidum* is very well known among naturalists, some contending for the earth, others for water, others for the air, and some of the moderns for nitre, but all seeming to agree that there is some body or other that is of its own nature supremely cold and by participation of which all other bodies obtain that quality." But with the general acceptance of the dynamical theory of heat, cold naturally came to be regarded as a negative condition, depending on decrease in the amount of the molecular vibration that constitutes heat.

The question whether there is a limit to the degree of cold possible, and, if so, where the zero must be placed, was first attacked by the French physicist, G. Amontons, in 1702-03, in connection with his improvements in the air-thermometer. In his instrument temperatures were indicated by the height at which a column of mercury was sustained by a certain mass of air, the volume or "spring" of which of course varied with the heat to which it was exposed. Amontons therefore argued that the zero of his thermometer would be that temperature at which the spring of the air in it was reduced to nothing. On the scale he used the boiling-point of water was marked at 73 and the melting-point of ice at $51\frac{1}{2}$, so that the zero of his scale was equivalent to about -240° on the centigrade scale. This remarkably close approximation to the modern value of -273° for the zero of the air-thermometer was further improved on by J. H. Lambert (*Pyrométrie*, 1779), who gave the value -270° and observed that this temperature might be regarded as absolute cold. Values of this order for the absolute zero were not, however, universally accepted about this period. Laplace and Lavoisier, for instance, in their treatise on heat (1780), arrived at values ranging from $1,500^{\circ}$ to $3,000^{\circ}$ below the freezing-point of water, and thought that in any case it must be at least 600° below, while John Dalton in his *Chemical Philosophy* gave ten calculations of this value, and finally adopted $-3,000^{\circ}\text{C.}$ as the natural zero of temperature. After J. P. Toule

had determined the mechanical equivalent of heat, Lord Kelvin approached the question from an entirely different point of view, and in 1848 devised a scale of absolute temperature which was independent of the properties of any particular substance and was based solely on the fundamental laws of thermodynamics (see HEAT and THERMODYNAMICS). It followed from the principles on which this scale was constructed that its zero was placed at -273° , at almost precisely the same point as the zero of the air-thermometer.

In nature the realms of space, on the probable assumption that the interstellar medium is perfectly transparent and diathermanous, must, as was pointed out by W. J. Macquorn Rankine, be incapable of acquiring any temperature, and must therefore be at the absolute zero. That, however, is not to say that if a suitable thermometer could be projected into space it would give a reading of -273° . On the contrary, not being a transparent and diathermanous body, it would absorb radiation from the sun and other stars, and would thus become warmed. (See J. H. Poynting, "Radiation in the Solar System," *Phil. Trans.* A, 1903.) The French physicists of the early part of the 19th century held a different view, and rejected the hypothesis of the absolute cold of space. Fourier, for instance, postulated a fundamental temperature of space as necessary for the explanation of the heat-effects observed on the surface of the earth, and estimated that in the interplanetary regions it was little less than that of the terrestrial poles and below the freezing-point of mercury, though it was different in other parts of space (*Ann. chim. phys.*, 1824, 27, pp. 141, 150). C. S. M. Pouillet, again, calculated the temperature of interplanetary space as -142°C . (*Comptes rendus*, 1838, 7, p. 61), and Sir John Herschel as -150° .

To attain the absolute zero in the laboratory, that is, to deprive a substance entirely of its heat, is a thermodynamical impossibility, and the most that the physicist can hope for is an indefinitely close approach to that point. The lowest steady temperature obtainable by the exhaustion of liquid hydrogen is about -262°C . (11° Abs.), and the liquefaction of helium by Prof. Kamerlingh Onnes in 1908 yielded a liquid having a boiling-point of about 4° Abs. which on exhaustion should bring us to within about 1° of the absolute zero. Liquid helium has since been solidified by Prof. Keesom (1926) at 1.3° Abs. under a pressure of 25 atmos. The freezing point rises to 4.2° Abs. under a pressure of 140 atmos. (See LIQUID GASES.)

COLD. The common cold (known technically as Acute Coryza) is an acute catarrhal inflammation of the upper respiratory tract, caused by infection with bacteria. The most careful bacteriological studies have failed to demonstrate a single specific germ as the cause of this disease; but the contagious character of many of these infections makes it almost certain that we are dealing with an infectious process. It is more likely that the common cold is not a specific infection like typhoid fever, which is always caused by the same micro-organism, but that it results from infection by any one of a number of different bacteria. The organisms most commonly found in the nasal secretions are the streptococcus, staphylococcus, pneumococcus and influenza bacillus. In addition to these well-known species, certain ultra-microscopic organisms have been isolated from the nasal secretions during colds.

Foster in 1916, and Olitsky and McCartney in 1923, described a filterable virus, which they claimed was capable of transmitting the common cold from infected individuals to healthy individuals. The fact that many species of bacteria are constant inhabitants of the healthy throat and nasopharynx has made bacteriological studies of the common cold extremely difficult, and it has been rather disturbing to find that this bacterial flora undergoes very little change in character during the acute stage of a cold. (Bloomfield, Dochez and others.) The common cold bears considerable resemblance to hay fever, and for this reason a prevalent theory as to its etiology is that acute coryza is an expression of a hypersensitive condition of the nasal mucous membrane to some protein, probably bacterial in nature.

The environmental factors causing the common cold are well-known. Unequal chilling of the body, sudden cooling after exer-

cise, wearing of wet shoes and wet clothing, fatigue and irritants in the air, all predispose to the onset of a cold. The exact effect of chilling of the body is not understood, but Mudd, Grant and Goldman have found that in experiments on human subjects, chilling of the skin invariably causes a lowering of the temperature of the skin, with a reflex lowering in temperature of the mucous membrane of the nose and nasopharynx. They believe that this drop in temperature depresses the resistance in the throat and thereby allows infection to take place.

Colds occasionally become epidemic. Epidemic colds are usually more severe than ordinary colds, and have been spoken of as grip, or influenza. It is probable that these epidemics are caused by some micro-organism, other than that producing the common cold.

The common cold usually starts in the posterior nares, or in the nasopharynx, but it may originate in any portion of the upper respiratory tract. The first symptom is a sensation of burning and discomfort in the part affected. As the infection spreads, the mucous membrane becomes red and swollen, the nostrils are occluded, and there is a profuse watery discharge from the nose. The patient complains of a dull headache, and a sense of congestion in the eyes, nose and throat. The voice is husky and the senses of taste, smell and hearing are impaired. The skin about the nostrils becomes red and excoriated. If the infection extends down into the bronchial tree, hoarseness develops and then a cough, which at first is dry and hacking, but later is accompanied by an expectoration of mucopurulent sputum. Involvement of the bronchial tree causes a sense of tightness and soreness in the chest, which may be increased with breathing.

The constitutional symptoms of acute coryza vary considerably with the patient, and with different infections in the same patient. In mild cases, there may be nothing more than slight languor and disinclination for exertion. In more severe cases there is some fever (100° to 102° F), rapid pulse, chilly sensations and aching in the back and extremities. Some patients develop gastro-intestinal symptoms, such as abdominal cramps, nausea, vomiting and diarrhoea. As a rule the common cold presents no diagnostic difficulty. Some of the infectious diseases, such as measles and scarlet fever, may begin with symptoms which are suggestive of coryza, but by the second or third day characteristic symptoms develop which make the differentiation easy. Grip and influenza are infections which are closely allied to the common cold. The differential diagnosis depends largely upon the severity of the symptoms. Grip is a term which is used rather loosely to designate an acute respiratory infection accompanied by some constitutional symptoms. It is really nothing more than a severe cold. Whether the causative agent is the same as that of the common cold is not known. Influenza is a highly contagious infection of the upper respiratory tract which occurs in large or small epidemics during which it spreads with remarkable rapidity. Many bacteriologists believe that it is caused by the influenza bacillus, but Olitsky and Gates have isolated a filterable virus, known as the *bacterium pneumocintes*, which they believe is the causative agent. The local symptoms of influenza are similar to those of coryza and grip, but the constitutional symptoms are much more marked. The fever is higher, and there is considerable prostration, associated with aching pains in the back and limbs. Influenza nearly always affects the bronchial tree, and a considerable number of patients develop influenzal pneumonia.

The complications of the common cold give the disease its medical significance. As a simple infection it runs a mild, short course, in many cases interfering but little with one's usual routine of life. The complications, however, are numerous and important. Bronchitis occurs so frequently that it can hardly be called a complication. Infection of the accessory sinuses is also extremely common, and sometimes brings on acute constitutional symptoms. More often a sinus infection simply means a prolongation of the nasal symptoms. Not infrequently the condition becomes chronic, and necessitates treatment by a nose and throat specialist. Involvement of the middle ear (otitis media) is a frequent complication, particularly in children, and may lead to a mastoiditis. Occasionally, the infection is not limited to the mastoid,

but extends through the bone and invades the meninges. When this happens, meningitis or brain abscess results. When the infection extends downward, bronchitis may be followed by bronchopneumonia or lobar pneumonia, and these in turn by pleurisy or empyema. In addition to these direct complications, the common cold may be the means of lighting up an old tuberculous process in the lungs, or, by lowering the resistance of the patient, it may lead to an exacerbation of some systemic condition, such as rheumatism, nephritis or heart disease.

TREATMENT

The common cold usually runs a definite course of three to ten days. If the nasal discharge persists longer than this, one should suspect a complicating infection of one of the sinuses. As recovery from the cold progresses, the congestion decreases, and the secretions become scanty and more purulent. The treatment consists largely in the relief of symptoms. Occasionally, a cold may be aborted in the early stage, but once the infection gets a start, efforts to check it are usually futile. Colds have been successfully aborted only when the infection has been checked at the very outset by the local application of some germicide, such as argyrol or silver nitrate. These applications should, of course, be made by a specialist, as it is almost impossible for the patient to reach the infected area with a gargle or spray. It has been claimed by some that measures which promote sweating sometimes check a coryza. The treatment usually advocated is a hot foot bath, some kind of hot drink, and a Dover's powder or a drink of whisky. Even if these measures fail, they tend to make the patient much more comfortable, and are certainly worth a trial. The best treatment for the common cold is rest in bed. Rest should be insisted upon if the temperature rises above 100° F, or if the patient is the victim of some chronic constitutional disease, such as diabetes or heart disease. The patient should be isolated as much as possible, not only to protect others, but to minimize the chances of acquiring a secondary infection at a time when the patient's resistance is at a low ebb. The diet should be simple and nutritious, and fluids should be taken in liberal amounts. Tobacco smoke, cold damp air and other irritants must not be allowed to enter the respiratory tract, as these tend to carry the infection down into the finer divisions of the bronchial tree. A saline cathartic is indicated, even when the bowels are active. Various drugs are used to counteract the unpleasant symptoms. Perhaps the most popular of these is aspirin, but phenacetin and codein are also popular. Locally, various sprays are used to lessen the irritation in the nose and throat. Most of the sprays have an albolene base to which has been added thymol, menthol or eucalyptol. If the infection invades the larynx or trachea, the voice should be rested as much as possible. If the cough becomes violent, some sedative, such as codein, is usually sufficient to control it. A favourite remedy is the old-fashioned croup kettle, containing a pint of hot water and a teaspoonful of compound tincture of benzoin. The patient is placed under a sheet and allowed to inhale the fumes from the steaming croup kettle. If there is much pain and tightness in the chest, counter-irritation with some stimulating liniment, or with a mustard plaster, often gives relief.

One of the most difficult problems which the modern health officer has to face is the prevention of the acute respiratory infections, particularly as the population tends more and more to concentrate in cities. Probably the most effective method of preventing colds is to reduce to a minimum contact with crowds. Yet such a measure is almost impossible to enforce in modern urban life. Antiseptic sprays and gargles have been advocated and are widely advertised, but their value is questionable. Most antiseptics strong enough to kill bacteria will cause irritation to the mucous membrane. Hardening the body by exposure to cold air or to cold water has been recommended to increase one's resistance to respiratory infections, but the value of this procedure has been very much questioned of late.

Vaccines are a very popular prophylactic and appear to have some value, particularly when prepared from the patient's own bacteria. Statistics by Park and Von Sholly among employees of the Metropolitan Life Insurance Company show that subjects

inoculated with "stock" vaccines contract colds about as readily as the uninoculated. For those, however, who suffer from repeated infections because of some chronic focus, an autogenous vaccine is well worth trying and often gives much relief.

L. C.)

COLDEN, CADWALLADER (1688-1776), American physician, historian and colonial official, was born at Duns, Scotland, on Feb. 17, 1688. He graduated at the University of Edinburgh in 1705, devoting himself to scientific studies there and in London, and emigrated to Philadelphia in 1710. There he engaged in general mercantile business until after a visit to Great Britain in 1715, when he began the practice of medicine. He was induced to move to New York by Governor Hunter, who appointed him the first surveyor-general of the colony and master in chancery. Becoming a member of the provincial council in 1721, he served for many years as its president; and from 1761 until his death was lieutenant-governor. He was acting-governor when in 1765 the stamped paper to be used under the Stamp Act arrived in the port of New York; a mob burned him in effigy in his own coach in Bowling Green, and he was compelled to surrender the stamps to the city council, by whom they were locked up in the city hall until all attempts to enforce the new law were abandoned. Subsequently Colden secured the suspension of the provincial assembly by an act of parliament. He understood, however, the real temper of the patriot party, and in 1775, when the outbreak of hostilities seemed inevitable, he strongly advised the ministry to act with caution and to concede some of the colonists' demands. When the war began he retired to his country seat near Flushing, N.Y., where he died on Sept. 28, 1776. Colden was widely known among scientists and men of letters in England and America. He was a lifelong student of botany, and was the first to introduce in America the classification system of Linnaeus, who gave the name *Coldenia* to a newly recognized genus. He wrote several medical works of importance in their day, the most noteworthy being *A Treatise on Wounds and Fevers* (1765); he also wrote an elaborate work on *The Principles of Action in Matter* (1751), which, with his *Introduction to the Study of Physics* (c. 1756), his *Enquiry into the Principles of Vital Motion* (1766), and his *Reflections* (c. 1770), mark him as the first of American materialists and one of the ablest material philosophers of his day. His *History of the Five Indian Nations* (1727, best ed. 1902) is one of the most valuable accounts that have been preserved of the relations with these powerful tribes and of the expansion of the English fur trade to the west.

Riley, *American Philosophy* (1907). Colden's *Letters and Papers* were published in the *Collections of the New York Historical Society* (1917-23).

COLD HARBOR, OLD and NEW, two localities in Hanover county, Virginia, U.S.A., 10m. N.E. of Richmond. They were the scenes of a succession of battles from May 31 to June 12, 1864, between the Union forces under command of Gen. U. S. Grant and the Confederates under Gen. R. E. Lee, who held a strongly entrenched line at New Cold Harbor. The main Union attack of June 3 was delivered by the 2nd (Hancock), 6th (Wright) 18th (W. F. Smith) Corps, and was brought to a standstill.

eight minutes. An order from army headquarters to renew the attack was ignored by the officers and men at the front, who realized fully the strength of the hostile position. These troops lost as many as 5,000 men in an hour's fighting, the greater part in the few minutes of the actual assault. In the constant fighting of May 31 to June 12 on this ground Grant lost 14,000 men. (See *WILDERNESS and AMERICAN CIVIL WAR*.)

COLD STORAGE: see REFRIGERATION.

COLDSTREAM, police burgh and parish, Berwickshire, Scotland. Pop. (1931), 1,922. It is situated on the north bank of the Tweed, here spanned by John Smeaton's fine bridge of five arches, erected in 1763-1766, 1½ m. south-west of Berwick by the L. N. E. R. The station is at Cornhill over the border. Owing to its position on the Border and also as the first ford of any consequence above Berwick, the town played a prominent part in Scottish history during many centuries. Here Edward I. crossed the stream in 1296 with his invading host, and Montrose with the Covenanters in 1640. Of the Cistercian priory, founded about 1165 by Cospatric of Dunbar, and destroyed by the 1st earl of Hertford in 1545, which stood a little to the east of the present market-place, no trace remains; but for nearly four hundred years it was a centre of religious fervour. Here the papal legate, in the reign of Henry VIII., published a bull against the printing of the Scriptures; but the site was occupied in the 19th century by an establishment, under Dr. Adam Thomson, for the production of cheap Bibles. At Coldstream General Monk raised in 1659 the celebrated regiment of Foot Guards bearing its name. Like Gretna Green, Coldstream was long a resort of runaway couples, the old toll-house at the bridge being the usual scene of the marriage ceremony. "Marriage House," as it is called, still exists. At Birgham 3 m. west, a place of no small importance, in 1188 William the Lion conferred with the Bishop of Durham concerning the attempt of the English Church to impose its supremacy upon Scotland; there in 1289 was held the convention to consider the marriage of the Maid of Norway with Prince Edward of England; and there, too, in 1290 was signed the treaty of Birgham, which secured the independence of Scotland. Seven miles below Coldstream on the English side, though 6 m. north-east of it, are the massive ruins of Norham Castle, made famous by Scott's *Marmion*, and from the time of its building by Ranulf Flambard in 1121 a focus of Border history during four centuries.

COLDWATER, a city near the southern boundary of Michigan, U.S.A., surrounded by beautiful lakes; the county seat of Branch county. It is on Federal highways 27 and 112, and is served by the New York Central railway system. The population in 1920 was 6,114; 1930 it was 6,735. It has large Portland cement plants, and manufactures furnaces, marine engines, grey-iron castings, brass, clothing, shoes, window-display fixtures, wooden sporting goods, sleds and lawn furniture. A State school and temporary home for children (opened 1874) is situated here. Coldwater (called Lyons until 1833) was settled in 1829, incorporated as a village in 1837 and as a city in 1861.

COLE: see ENNISKILLEN, WILLIAM WILLOUGHBY COLE.

COLE, SIR HENRY (1808-1882), English civil servant, was born at Bath on July 15, 1808. He was a leading member of the commission that organized the Great Exhibition of 1851, and then became secretary to the School of Design, which was transferred in 1853 into the Department of Science and Art. Under its auspices the South Kensington (now Victoria and Albert) Museum, London, was founded in 1855 and Cole practically became its director, retiring in 1873. He originated the scheme for the Royal Albert Hall, London. He was active in founding the national schools for cookery and music, the latter the germ of the Royal College of Music. He edited the works of Thomas Love Peacock. He died on April 18, 1882.

See *Fifty Years of Public Work of Sir Henry Cole*, ed. A. S. and H. Cole (1884).

COLE, THOMAS (1801-1848), American landscape painter, was born at Bolton-le-Moors, England, on Feb. 1, 1801. In 1819 the family emigrated to America, settling first in Philadelphia and then at Steubenville (O.), where Cole learned the rudiments of his profession from a wandering portrait painter named Stein. He went about the country painting portraits, but with little financial success. Removing to New York (1825), he displayed some landscapes in the window of an eating-house, where they attracted the attention of the painter Colonel Trumbull, who sought him out, bought one of his canvases, and found him patrons. From this time Cole was prosperous. He is best remembered by a series of pictures consisting of four canvases representing "The Voyage of Life," and another series of five canvases representing "The Course of Empire," the latter now in the gallery of the New York Historical Society. They were allegories, in the taste of the day, and became exceedingly popular, being reproduced in engravings with great success. The artist's genuine fame must rest on his landscapes. He had an influence on his time and his fellows which was considerable, and with Durand he may be said to have founded the early school of American landscape painters. Cole spent the years 1829-32 and 1841-42 abroad, mainly in Italy, and at Florence lived with the sculptor Greenough. After 1827 he had a studio in the Catskills which furnished the subjects of some of his canvases, and he died at Catskill (N.Y.) on Feb. 11, 1848. His pictures are in many public and private collections. His "Expulsion from Eden" is in the Metropolitan Museum in New York city: and is one of the most typical examples of his style.

COLE, TIMOTHY (1852-), American wood engraver, was born in London in 1852, his family emigrating to the United States in 1858. He established himself in Chicago, where in the great fire of 1871 he lost everything he possessed. In 1875 he removed to New York, finding work on the *Century* (then *Scribner's*) magazine. He immediately attracted attention by his unusual facility and his sympathetic interpretation of illustrations and pictures, and his publishers sent him abroad in 1883 to engrave a set of blocks after the old masters in the European galleries. These achieved for him a brilliant success. His reproductions of Italian, Dutch, Flemish, and English pictures were published in book form with appreciative notes by the engraver himself. Though the advent of new mechanical processes had rendered wood engraving almost a lost art and left practically no demand for the work of such craftsmen, Mr. Cole was thus enabled to continue his work, and became one of the foremost contemporary masters of wood engraving. He received a medal of the first class at the Paris Exhibition of 1900, and the only grand prize given for wood engraving at the Louisiana Purchase Exposition at St. Louis in 1904. He is an honorary member of the Society of Sculptors, Painters and Engravers, London, and a member of the American Academy of Arts and Letters. He is the author of *Notes to Old Italian Masters*, and other critical essays.

COLE, VICAT (1833-1893), English painter, born at Portsmouth on April 17, 1833, was the son of the landscape painter, George Cole, and in his practice followed his father's lead with marked success. He became an Academician in 1880, and died in London on April 6, 1893. Most of his subjects were found in the counties of Surrey and Sussex, and along the banks of the Thames. One of his largest pictures, "The Pool of London," was bought by the Chantrey Fund Trustees in 1888, and is now in the Tate Gallery.

See Robert Chignell, *The Life and Paintings of Vicat Cole, R.A.* (1899).
